HARMSWORTH SELF-EDUCATOR

1907

Vol. VII. Pages 5233—6096

A KEY TO THE HARMSWORTH SELF-EDUCATOR

At the heading of each article in the Self-Educator is the number of the group to which the article belongs, and a reference to this key indicates precisely the place of the article in the scheme of the book. This key, therefore, enables the student at any time to understand what has preceded and what is to follow any part of the work to which he may happen to turn.

Group 1.
Agriculture. Beekeeping. Gardening.

Farming. In all its Branches. Dairying. Poultry.
Beekeeping. A Practical and Commercial Course.
Gardening. How to Get the Most out of a Minimum of Land. Gardening for Pleasure and Profit. Market Gardening.

Group 2.
Art. Architecture. Glass. Earthenware. Carving.

Art. Theory and Training. Painting. Sculpture. Architecture (Theory. Styles. Practical Training). History and Ideals of Art.
Glass and Earthenware. Including Pottery.
Carving. Wood. Bone. Ivory. Horn. Tortoiseshell.

Group 3.
Biology. Psychology. Sociology. Logic. Philosophy. Religion.

Biology. Including Evolution, Palæontology, Heredity, Anthropology, Ethnology.
Psychology. Including Psychical Research.
Sociology. Including Political Economy.
Logic. The Science of Reasoning.
Philosophy. Systems of Thought.
Religion. History and Systems. Christianity.

Group 4.
Building. Cabinet Making. Upholstering. Fire.

Building. Excavating. Drainage. Manufacture of Bricks, Limes, and Cements. Bricklaying. Clay Wares. Reinforced Concrete Masonry. Carpentry. Slates and Tiles. Plumbing. Joinery. Foundry and Smiths' Work. Painting, Paperhanging and Glazing, Heating, Lighting, and Ventilation. Building Regulations Quantity Surveying. Building Abroad. In Business as a Builder
Cabinet Making and Upholstering. A Practical Course.
Fire. Fireproof Materials. Fire Prevention. Fire Extinction.

Group 5.
Chemistry and Applied Chemistry.

Chemistry. Inorganic and Organic. Chemistry of the Stars.
Applied Chemistry. Acids and Alkalies. Oils (Fixed Oils and Fats; Waxes; Essential Oils and Perfumes; Paints and Polishes). Candles. Soaps. Glycerin. Glues and Adhesives. Starches. Inks. Tar and Wood Distillation. Matches. Celluloid. Manure. Waste Products. Petroleum. Paper Making (including Paper Staining and Uses of Paper). Photography.

Group 6.
Civil Service. Army and Navy.

Civil Service. Municipal. National. Imperial.
Army and Navy. How to Enter Them.

Group 7.
Clerkship and the Professions.

Clerkship and Accountancy. Complete Training. Bookkeeping.
Banking. The Whole Practice of Banking.
Insurance. Life, Fire, Accident, Marine.
Auctioneering and Valuing. Practical Training.
Estate Agency. Departments and Officials of a Great Estate. Training a Land Agent.
Medicine. Training of a Doctor. Specialists. Veterinary Surgeons. Dentistry: The Dental Mechanic. Home and Professional Nursing.
Church. How to Enter the Ministry of all Denominations.
Scholastic. Teachers. Professorships. Governesses. Coaches. Tutors.
Secretaries, etc. Institution Officials. Political Organisations. Lecturers.
Law. Solicitors and Barristers. Personal and Commercial Law. Copyright.

Group 8.
Drawing and Design.

Drawing. Freehand. Object. Geometrical. Brush. Memory. Light and Shade.
Technical Drawing. For Engineers; Coppersmiths, Tinmen, Boilermakers; Architects; Stonemasons; Carpenters and Joiners; Plumbers.
Design. Book Decoration. Illumination. Textiles. Wall Papers and Stencilling.

Group 9.
Dress.

Dress. Dressmaking. Underclothing. Children's Clothing. Tailor- [illegible] Hats. Furs and Furriers. Feathers.

[illegible]

Electricity. Electrical Engineering. Telegraphs and Telephones (including operation of). Cables and Insulated Wire. In Business as an Electrical Engineer.

Group 11.
Civil Engineering.

Civil Engineering. Surveying. Varieties of Construction. Machines Employed. Roads. Bridges. Railways and Tramways. Water Supply. Sewerage. Refuse. Hydraulics. Pumps. Harbours. Docks. Lighthouses. Foreign Work. In Business as a Civil Engineer.

Group 12.
Mechanical Engineering. Military Engineering.

[illegible] Applied Mechanics. Workshop Practice. [illegible] Machine Tools. Portable Machine [illegible]

Military Engineering. Pontoons. Bridges. Fortifications. Rafts. Trenches. Passing Rivers. Conditions in [illegible] War.
Arms and Ammunition. Manufacture of Arms [illegible] Explosives.

Group 13.
Geography. Astronomy.

Geography. Physical. Political. Human. Commercial.
Astronomy. A Survey of the Solar System.

Group 14.
Geology. Mining. Metals and Minerals. Gas.

Geology. The Making of the Earth.
Mining. The Practice of Mining: Coal, Gold, Diamonds, Tin, etc.
Metals. Metallurgy. Iron and Steel. Iron and Steel Manufactures. Metal Work. Cutlery.
Minerals. Mineralogy. Properties of Minerals.
Gas. Manufacture of Gas.

Group 15.
History.

A Short History of the World from the Beginning.

Group 16.
Housekeeping and Food Supply.

Servants. Qualifications and Duties of Every Kind of Servant.
Cookery. A Practical Course, with Recipes.
Laundry Work. Washing. The Laundry as a Business.
Foods and Beverages. Milling. Bread-making. Biscuits and Confectionery. Sugar. Condiments. Fruit. Fisheries. Food Preservation Catering. Brewing. Wines and Ciders. Mineral Waters. Tea. Coffee. Chocolate. Cocoa.

Group 17.
Ideas. Patents. Applied Education.

Ideas. The Power of Ideas in Life. Brains in Business.
Patents and Inventions. How to Protect an Idea.
Applied Education. Application of Education in Daily Life. Finance.

Group 18.
Languages.

How to Study a Language. Courses in Latin, English, French, German, Spanish, Italian, Esperanto, Greek. A Table of Root Words.

Group 19.
Literature. Journalism. Printing. Publishing. Libraries.

Literature. A Survey of the World's Great Books and their Writers. Poetry. Classics. Fiction. Miscellaneous. How to Read and Write.
Journalism. A Guide to Newspaper Work, with Practical Training.
Printing. Composing by Hand and Machine. Type Cutting and Founding. Engraving and Blocks. Bookbinding and Publishing.
Libraries. Officials and Management of Libraries.

Group 20
Materials and Structures. Leather. Wood Working.

Materials. The Characteristics and Strength of Materials.
Structures. The Stability of Structures.
Leather. Leather Industry. Leather Belts. Boots and Shoes. Saddlery and Harness. Gloves. Sundry Leather Goods.
Wood Working. Design and Operation of Wood Working Machinery. Wood Turning. Miscellaneous Woodwork.

Group 21.
Mathematics.

Mathematics. Arithmetic. Algebra. Geometry. Plane Trigonometry. Conic Sections.

Group 22.
Music. Singing. Amusement.

Music. Musical Theory. Tonic Solfa. Tuition in all Instruments. Orchestration. Conducting. Bell Ringing. Manufacture of Musical Instruments.
Singing. The Voice and Its Treatment.
Amusement. Drama and Stage, including Elocution. Business side of Amusement. Sports Officials.

Group 23.
Natural History. Applied Botany. Bacteriology. Natural Products.

Natural History. Botany: Kingdom of Nature—its Marvels, Mechanism, and Romance; Flowers, Plants, Seeds, Trees, Ferns, Mosses, etc. Zoology: Animals, Birds, Fishes, Reptiles, Insects.
Applied Botany. Tobacco & Tobacco Pipes. Forestry. Rubber and Gutta Percha. Basket Making. Cork, Wattle. Cane Work. Barks. Brush Making.
Bacteriology. Pathological and Economic.
Natural Products. Sources. Values. Cultivation.

Group 24.
Physics. Power. Prime Movers.

Physics. A Complete Course in the Science of Matter and Motion.
Power. A General Survey of Power. Natural Sources. Liquid and Compressed Air.
Prime Movers. Engines. Steam. Gas. Heat. Turbines.

Group 25.
Physiology. Health. Ill-health.

Physiology. Plan of the Body. Digestive. Circulatory. Respiratory, Locomotor and Nervous Systems. The Senses.
Health. The Five Laws of Health. Personal Hygiene. Environment. State Medicine and the Public Health.
Ill-health. General Ill-health. Its Special Forms. Common Ailments and Domestic Remedies.

Group 26.
Shopkeeping. Business Management. Publicity.

Shopkeeping. A Practical Guide to the Keeping of all Kinds of Shops.
Business Management. The Application of System in Business.
Publicity. Advertising from all Points of View As a Busin[illegible]

Group 27.
Shorthand and Typewriting.

Shorthand. Taught by Pitmans.
Typewriting. Working and Management of all Machines.

Group 28.
Textiles and Dyeing.

Textiles. The Textile Trades from Beginning to End.

Group 29.
Travel and Transit.

Travel. How to See the World. The Business Side of Travel.
Transit. A General Survey of Means of Communication.
Vehicles. Construction of Air, Land and Sea Vehicles. Business of a Liveryman, Carrier, etc. Driving.
Railways. The Management and Control of Railways.
Ships. Shipbuilding. Shipping. Management of Ships.

SOME EXAMPLES OF MODERN POTTERY

A. Striated Opalescent glaze. B. Rouge Flambé and Hare[illegible] C, D, G, K, O, P, Q, and S. Rouge Flambé and Mottled. E. Green Sun-stone glaze with small golden crystals. F. Apple green glaze (like the Chinese). H. Purple glaze. J. Fiery Crystalline glaze. L. Opalescent glaze, resembling the glazes of the early Sung porcelains of the Chinese. M. Flambé glaze of rich green, with cloudings of mulberry colour. N. Rouge Flambé flower pot. R. Pure Rouge Flambé. From examples executed by Pilkington's Tile and Pottery Co., Ltd., Manchester, and Messrs. Doulton & Co., Ltd., Burslem. [See POTTERY.]

MOULDING AND FIRING CLAY

Manipulation of the Clay. Biscuit Ovens and Biscuit Firing. How Glaze is Prepared and Applied to Biscuit Ware

Group 2
EARTHENWARE
2
POTTERY

continued from page 5162

By MARK SOLON

THE moulding of the clay into the various forms required may be done in a great many ways, according to the shape and size of the piece.

Throwing. The most ancient method, and one still in use, is by means of a *thrower's wheel*, a modern type of which is shown in **8**. The thrower sits over the revolving disc, A, into the centre of which he throws the piece of clay. By pressing the sides or the top of the mass while in motion he raises or depresses it, or may hollow it out by the pressure of his fingers, making any regular circular shape he wishes.

The speed at which the disc is driven is regulated by the movable driving cone B, which is actuated by the lever C. The operator, by working the lever alters the pitch of the driving cone B, bringing a larger or smaller driving surface to bear upon the cone D; thus, by pressing down the lever the base of the driving cone is brought into contact with the apex of the cone D, increasing the speed of the disc, and by reversing the movement the speed is accordingly decreased. The cone B is driven by a rope passing round the pulley E.

The operator regulates the machine to the size of the piece he is throwing, decreasing the speed for the larger pieces and accelerating it for the smaller.

Turning. After the rough form has been *thrown*, it is placed in a heated chamber and allowed to dry until sufficiently hard to handle. It is then finished, and the accurate shape given to it on a turner's lathe [**9**]. This lathe is similar to that employed by a wood-turner. The pieces are fixed upon the horizontal spindle, A, in the manner shown in the diagram, the mouth of the article being forced on to a wooden cone. When set in motion the superfluous clay is cut away with small steel tools and the piece turned to the correct shape. The spindle is then made to revolve in the opposite direction and the surface of the clay polished with flat pieces of steel.

The other processes of moulding the clay and those most extensively used are *pressing*, by machine and by hand, and *casting*.

Machine Pressing. The *pressing* of plates is perhaps the simplest form of mechanical pressing, the machine being called a *flat jigger* [**10**, A]. It consists of a revolving spindle to the head of which is attached an iron frame or ring; on this ring is placed the plaster mould, which is an exact replica in plaster of Paris of the inside of the plate. Working in conjunction with the flat jigger is a *batting machine* [**10**, B], which mechanically prepares the slab or bat of clay with which the plate is to be made. It consists of a revolving spindle, upon which is fixed a round plaster block, B [see diagram **10**, B]; the piece of clay is thrown into the centre of the block, which is put in motion; the steel "spreader," C, then descends, flattening out the clay to the proper size and thickness.

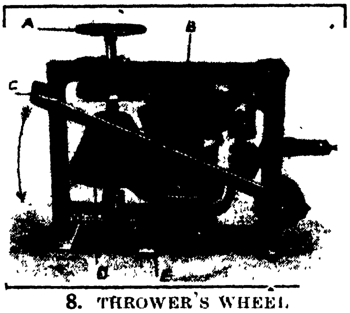
The workman places the bat of clay upon the mould and puts the latter on to the ring, D [see diagram **10**, B], which forms the head of the jigger.

A steel profile, A, which works upon a hinge, is brought to bear upon the clay, pressing it against the mould and at the same time giving the shape to the back of the plate. The mould, with the shaped piece of clay upon it, is put into a heated chamber and dried. The face of the plate is afterwards polished with fine sandpaper and the edges rounded with small steel tools.

Jollying. Another form of machine pressing is known as *jollying*, and is employed in the production of circular hollow pieces. In this case the plaster mould forms the outside of the article and the steel profile the inside. The machine [**11**] is of similar construction to the flat jigger. The head, however, is in the form of a metal cup, and the mechanical arrangement for introducing the profile is different. The mould is made in two parts, which are held together by an outer plaster frame. This frame fits accurately into the hollow metal head of the machine.

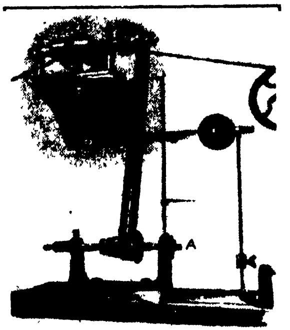
After the slab of clay has been formed by a batting machine as already described, it is roughly shaped upon a circular block of plaster which is covered by a loose flannel cap. The block, with the clay upon it, is inverted into the hollow mould, and on being withdrawn leaves the shaped piece of clay resting within the mould. The machine is then set in motion, and the operator with the wet sponge presses the clay against the mould, expelling the air from between them; the steel profile is then introduced, which gives the correct shape and finish to the inside of the piece.

Hand Pressing. The foregoing processes only apply to circular shapes; square and irregular pieces must be pressed by hand. If we take as an example of this method an ordinary jug, the mould is made in two pieces [**13**]. Flat slabs or *bats* of clay are beaten out by the workmen upon a plaster block, with a mallet of the same material, and placed upon the mould; the clay is then pressed against the mould by means of wet sponges and flat pieces of india-rubber. Both sides of the mould having been lined in this way with clay, the two halves are put together and the seam between them filled in with a small roll of plastic clay. The handle of the jug is pressed from a solid roll of clay between two plaster moulds. After being partially dried, it is fitted to the shape of the jug, the ends are dipped into thick slip, placed in position on the jug, and by gentle pressure made to adhere. After drying, the rough edges are trimmed with a knife, and the surface finished with fine moist sponges.



8. THROWER'S WHEEL

Casting. In the process of casting, instead of using the plastic clay we take the slip before the superfluous water has been filtered from it. This method is resorted to when either very thin or highly ornamented pieces of intricate shape are required. Having taken the hollow plaster mould, which is naturally extremely absorbent, it is filled with slip. Immediately, the plaster absorbs the water from the slip which comes in contact with it, coating the mould with a thin film of clay; the superfluous slip is then emptied from the mould, the clay piece remaining in it until hard enough to remove. After drying, it is finished in the usual way with moist camel-hair brushes and fine sponges.



9. TURNER'S LATHE

Reference has been made to plaster moulds which depend the shape and modelled ornamentation of pressed or cast pieces. These moulds, which are made of plaster on account of the case with which it can be manipulated and its power of absorbing water, are cast successively from clay or plaster model by pouring the liquid plaster (plaster mixed with water) round the model, and allowing it to set. In this way the ornamentation or relief worked upon the original can be reproduced in any quantity.

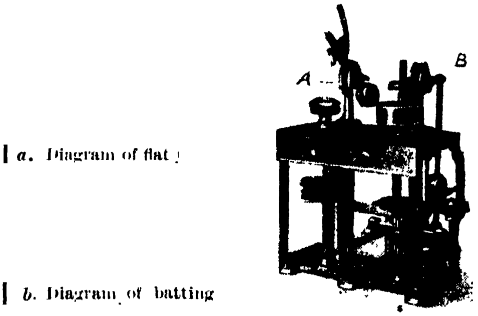
Drying. After the clay has been moulded by any of the foregoing methods the pieces are hardened by *drying*, so that they may be safely handled for finishing. In other words, the water, which to a large extent has been artificially introduced to aid plasticity, is driven off. This brings about a diminution in the bulk of the clay, which is called contraction or shrinkage.

In each workshop is built a stove, or drying chamber, heated from the floor by means of steam pipes. The interior of the chamber is fitted with shelves upon which the moulds are put. When a large number of moulds are used, as in the case of plate and saucer making, the shelves are arranged upon an upright spindle, which revolves inside the stove [12]. The shelves are constructed in distinct sections, which, on turning the spindle, present themselves in rotation at the opening of the stove. In this way only one section at a time is exposed in the workshop, and this, when filled with moulds, is turned into the heated chamber. The shelves are thus filled and emptied continuously, the time taken for each revolution of the spindle being sufficient to dry the clay thoroughly.

It is necessary in drying that the evaporation of water should take place evenly and slowly, otherwise the clay will have a tendency to twist and crack, giving way always in the weakest part. The speed with which the drying may safely proceed depends upon the amount of water to be expelled, or the extent to which the body is liable to contract. This varies according to the proportion of plastic materials it contains. The higher the proportion the greater the contraction, and consequently the more slowly and carefully must the piece be dried.

Biscuit Firing. We come now to the most difficult and important process in pottery manufacture—*biscuit firing*, or hardening of the clay in order to make it durable and capable of being glazed. This hardening, or vitrification, is characterised by a further contraction due to the chemical combination of the ingredients in the body under the influence of heat. In order to raise the clay to the desired temperature, furnaces, or *biscuit ovens*, as they are called, are built, capable of holding a considerable quantity of ware. The construction of these ovens varies considerably, but the simplest forms, and those generally adopted, are the *up-draught* and *Minton's Patent*. We must bear in mind in studying the construction of these ovens that the main object is the uniform and economical distribution of heat through the entire mass.

The Up-draught Oven. The up-draught oven [14] consists of a circular chamber round the base of which are from 8 to 12 fire holes or mouths. The chamber is built within a large conical chimney. On leaving the mouths, the fire ascends through the oven by upright



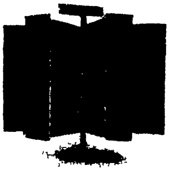
10. PRESSING AND BATTING MACHINE
(W. Boulton, Ltd., Burslem)

and horizontal flues ; the former serve to heat the outside circumference, while the latter convey the flame to the centre. The products of combustion from both escape through holes in the dome top. The fires are fed with coal through openings at the top of the mouths.

These openings are fitted with iron doors or fireclay slabs, which, being entirely or partially closed, regulate the amount of air passing into the oven.

The Down-draught Oven. The Minton's Patent, or *down-draught* oven [15], differs considerably from the up-draught in construction and principle. The general arrangement of the fire holes is the same, but it will be noticed that there is no independent chimney or hovel, the chimney being built upon the body of the oven itself. The great difference in principle, however, is the course taken by the flame. The fire holes are connected with the interior of the oven by upright flues only ; on leaving these flues, the flame ascends to the top of the dome. The opening, A, however, being closed, the products of combustion are reflected to the floor, and, passing through holes in the bottom of the oven, B, escape eventually by the vertical flues, C, built in the walls. The course taken by the flame in this case is much more lengthy than in the case of the up-draught oven, and results in more perfect combustion and consequent economy of fuel.

The Saggers. Having briefly described the construction of the oven, we will pass on to the method in which the clay ware, already dried, is placed in the inner chamber and fired. In order to protect the clay from the fire, and also so that the oven can be properly filled, the pieces are first of all put into fireclay boxes, or *saggers*. These saggers are made from coarse local marls which occur in the coal districts, and are of size and shape to suit the particular class of goods for which they are intended. The marl, after being mined from the pit, is crushed between metal rollers and mixed in a horizontal pug mill with about a third of its weight of previously fired marl, the requisite amount of water being added to make the mixture plastic. In practice, the saggers, which have already been fired and become useless or broken, are ground up and used to mix with the marl. The object of introducing the fired material is to reduce the contraction and enable the saggers to withstand sudden changes of temperature when the oven is cooling. Up to recently, these saggers have been almost universally made by hand, but latterly machines have been designed which, although not perfect, will doubtless eventually supersede the hand methods



12. REVOLVING SPINDLE FOR DRYING MOULDS

13. JUG-MAKING

The prepared marl is first of all beaten by hand with wooden mallets on an iron table into flat sheets of about 1 in. thickness. The sheets are then cut with a knife into strips, the width of the strip corresponding to the height of the sagger required. The shape is given by wrapping these strips round wooden boxes or drums, which are afterward placed upon flat bats of marl the size and shape of the bottom of the sagger. The strips which form the sides are then worked into and welded to the bottom, thus forming a complete box ; these are then slowly dried and sent to the oven to be fired.

11. JOLLYING
(Boulton & Co., Ltd., Burslem)

Filling the Oven. The clay ware is simply placed inside the saggers, packed as closely as possible, clean sand being used to support it where necessary. The saggers are arranged one upon the other in the oven as shown in 18, those containing such pieces as ewers, jugs, cups, and the majority of small hollow ware being placed in the hottest parts of the oven, while the plates, dishes, etc., are kept in the centre, away from the fire holes. After the entire oven has been filled as solidly as possible with saggers, the entrance is built up and made air-tight.

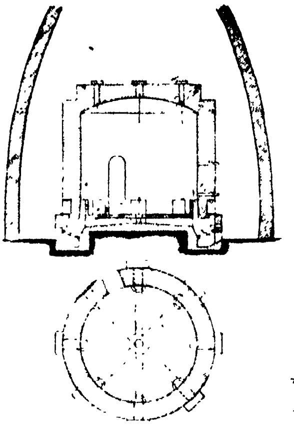
Firing the Biscuit Oven. The firing, as we have already said, must proceed slowly and evenly, our object being to raise the entire mass in the oven to one uniform heat, and to bring about the contraction of the clay equally and continuously. The time taken to fire a biscuit oven is from 48 hours to 60 hours, and may be divided into three stages.

During the first stage, or *smoking*, the fires are very slight, as it is only necessary to create a gentle heat in the oven just sufficient to drive off any free moisture which may have remained in the ware or unfired saggers. This treatment lasts for about twelve hours, until the whole of the oven is thoroughly warmed.

During the second stage the heat is gradually raised for about 24 hours. The clays now lose their combined water, which is driven off at about red heat. The body, however, does not undergo any marked change, and remains about the same size, but losing a little of its density. Great care must be taken not to increase the heat too rapidly, otherwise the outer part of the oven will become very much hotter than the centre, a difference which cannot afterwards be rectified.

The third stage, which we might consider as the firing proper, begins with the contraction of the body. The fireman controlling the oven must then be guided by whatever pyrometer he is using as to the correct manner to treat his fires in order to bring about the entire shrinkage in an even and regular manner.

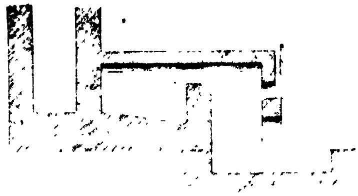
Pyrometers. The *pyrometers*, on which depend, to a great extent, the ultimate result of the firing, may be divided into two classes—those indicating the heat required, and those showing the effect of the heat on the material.



14. UP-DRAUGHT BISCUIT OVEN

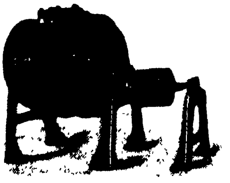
Of the first class, the "Seger cones" are the most generally used and the most reliable. They are composed of more or less fusible felspathic mixtures so adjusted that they bend or melt at given temperatures. Having placed a number of them in the sight-holes of the oven, the fireman, by making periodical observations, sees exactly what heat he has attained.

In the second class, the actual material being fired is used. Small pieces of the dried body, or "trials," are put in the oven as before, but arranged in such a way that they can be easily drawn out and examined. The fireman then judges the heat by measuring the contraction of the trials or by observing the texture of the fracture when the piece is broken. The latter method is extensively used. By allowing the small pieces to cool very quickly, they split. The denser the body, the closer the particles; consequently, the smoother the fracture. The appearance of this fracture becomes then an indication of the density of the body, or of the heat to which it has been submitted.



16. FRITTING FURNACE

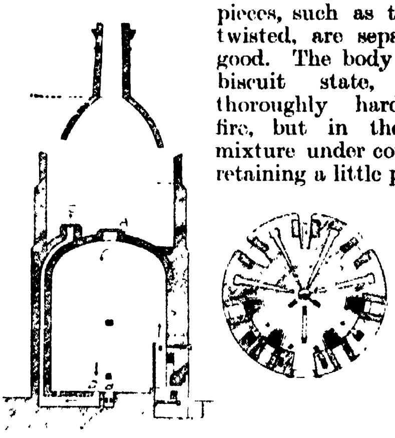
The second class is undoubtedly the more reliable one, as the increase in heat does not always correspond with the molecular work done in the body. There are certain periods during the firing when chemical combinations take place in the body which bring about the shrinkage, so that, in order that the contraction of the ware should occur evenly, the heat at these periods must be to a certain extent withheld.



17. ALSING CYLINDER

After the right temperature has been reached, the oven is allowed to cool slowly.

Should the cooling proceed too rapidly, the larger and thicker pieces of ware will have a tendency to split, the outside of the piece becoming cold while the centre is still hot, and causing an unequal contraction. When the whole of the oven has become thoroughly cool, the ware is drawn out and examined, and the faulty pieces, such as the cracked and twisted, are separated from the good. The body is now in the biscuit state, having been thoroughly hardened by the fire, but in the case of the mixture under consideration, still retaining a little porosity.



15. MINTON'S PATENT OR DOWN-DRAUGHT BISCUIT OVEN

Glazing. The foundation of all glazes is the silica or flint rendered fusible by the addition of fluxes, such as borax, carbonate or oxide of lead, lime, soda, and potash. These materials, mixed in suitable proportions and melted together, produce a glass which harmonises with the biscuit to which it is applied.

Equal Contraction and Expansion. It is particularly necessary that the glaze should be so composed that it has a similar contraction and expansion to the body which it covers. The glaze, like the body, expands with heat and contracts with cold, and unless the body and glaze contract and expand simultaneously, two faults are developed. In the first place, should the glaze contract on cooling more than the body, it breaks up, the surface becoming covered with fine cracks or *crazes*. If, on the other hand, the body contracts more than the glaze, it is apt to compress the glaze, which, after it has been compressed beyond the limit of its elasticity, acquires sufficient pressure to break the piece.

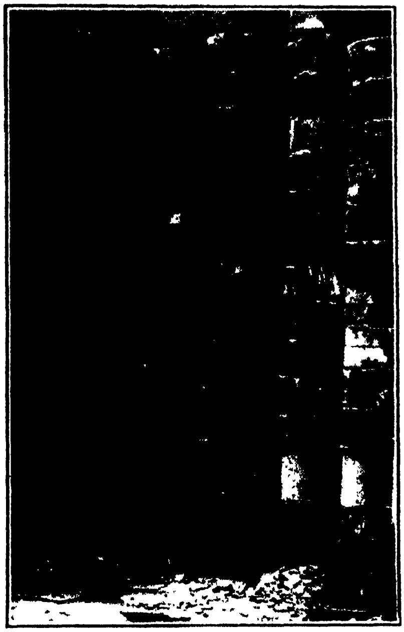
The peculiar properties of the various fluxes used in combination with the flint are as follows:

The *borax* gives brilliancy and hardness to the glaze, and has the property of covering a large surface in proportion to its weight. The *lead* makes the glass elastic and lustrous, and at the same time forms a more stable glass, which is not so easily affected by subsequent repeated fires. The lime is introduced for its stability and transparency when in combination with the silica and borax. *Soda* and *potash* are the most fusible fluxes, and greatly affect the melting point of the glaze.

It must be borne in mind that these properties are due to the *combination* of the ingredients and to their effect upon one another when melting.

Preparation of the Glaze. Our object now is to produce a mixture from the above materials which, when ground to a finely divided state, shall be stable, and in no way soluble in water. However, certain of the ingredients necessary for the glass, such as borax, soda and potash, are extremely soluble in water, and the first process in glaze-making is to render them insoluble by combining them with certain proportions of silica, Cornish stone, lime, china clay, etc. This is done by intimately mixing together the materials and melting them in a specially constructed furnace [16]. This process is called *fritting*, and the glass so produced the *frit*. A further quantity of flint, lead, and stone is then added to the frit, and the whole mixture ground in water.

The mill already described has, till recently, been used for glaze grinding, but it has now been superseded by the "Alsing cylinder," a rotary mill [17]. This machine takes considerably less power to drive, and grinds more rapidly. It consists of a cylinder lined with chert porcelain, or wood, which is half filled with small flint boulders. The frit and mixture is introduced into the cylinder with a certain amount of water. On making the cylinder revolve slowly the flints rub against each other, and the glaze lying between and about the boulders is ground by the friction between their surfaces. After it has been passed through fine silk sieves, and the metallic iron extracted from it by ordinary magnets, the liquid glaze is delivered into tanks.



18. METHOD OF ARRANGING SAGGERS IN BISCUIT OVEN

Applying the Glaze to the Ware. The liquid glaze is applied to the ware by plunging the porous pieces of biscuit into the liquid, the porousness ensuring the retention of a sufficiently thick coating. The evenness of the coating depends upon the manner in which the piece is dipped into the liquid and the superfluous glaze shaken from it.

After being thoroughly dried, the ware is again placed in saggers, which are built up in the oven in the manner already described for biscuit firing, with the exception that the joint between every sagger is made airtight by the insertion of rolls of plastic clay.

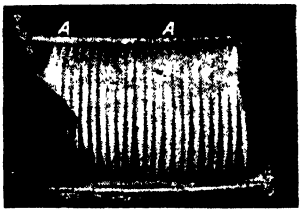
The method of placing the ware, however, is different, as the pieces must be kept from contact with one another or with the sagger, to prevent the glaze, when molten, causing them to adhere. To accomplish this the articles are separated by various shaped small pottery supports called *thimbles, stilts* and *saddles*. Fig. 19 shows the arrangement for placing plates or saucers, the thimbles, A, being so formed that they can be built up one on another, so that the ware only comes into contact with the pointed arm.

After the glaze has been cleaned from the foot, hollow pieces, such as jugs, cups, ewers, etc., are placed on the bottom of the sagger, upon which some small flint chippings have been previously strewn. These chippings provide small pointed supports for the pieces, and so prevent them from adhering to the bottom of the sagger.

The composition of the glaze suitable for the body given at the beginning of this article is as follows:

Frit—	
Borax	30
Flint	18
Stone	18
Whiting	10
China Clay	8
Carbonate of lead	16
Mixture to mill—	
Frit	55
Stone ..	32
Flint	5
Carbonate of lead	8

Glost Firing. The *glost firing*, or remelting of the glaze upon the surface of the biscuit, must proceed briskly, and occupy from about 18 to 24 hours. The fireman gauges the progress of the heat by drawing from the oven periodically small rings, or trials, made of a lightly fired red marl and dipped in a soft-red glaze, which darken as the heat increases. It is extremely important during the whole process of glost firing that the atmosphere inside the oven should be kept as oxidising as possible. In other words, if insufficient air for combustion be admitted through the fire holes, the products of combustion become laden with carbon, which, in order to burn, will rob the lead and other compounds in the glaze of their oxygen and so affect the brilliancy of the piece. For this reason the ovens are cooled very quickly, allowing as much air as possible to pass through the oven while the glaze is still in the molten state. It must be understood that the brilliancy of the glaze on the ware depends to a very great extent upon the oxygen which is contained in the fluxes.



19. PLATES ARRANGED FOR GLOST FIRING *a.* Thimbles

When it has been drawn from the oven the ware is carefully examined for faults, the small rough places, where each piece has been supported during firing, being dressed and smoothed with steel tools.

HISTORY
37

NAPOLEON

A Short Story of a Great Career. Napoleon's Triumphs and his Fall. The Restoration of the Bourbons. France Again Under a Republic

By JUSTIN McCARTHY

THE movement of the great French Revolution was brought to a close, for a time at least, by the career of Napoleon Bonaparte. Napoleon may be ranked as soldier, conqueror, and dictator even with Julius Cæsar, although he had none of Cæsar's gifts as historian, orator, and statesman. He came of an ancient Corsican family, and was born at Ajaccio, August 15th, 1769. When ten years old, he was sent to a military academy, and five years afterwards was removed to a school of the same order in Paris. He entered soon after a regiment of artillery as second lieutenant. His rise was so rapid that in February, 1796, he was appointed General in command of the army in Italy, which had then for its chief enemies the forces of Austria.

He won many victories over the Austrians and Piedmontese, and at the famous battle of Lodi gained a complete victory over the Austrian forces, and entered Milan in triumph. The contest, however, was still continued with great obstinacy on the part of the Austrians. The great European powers now began to regard Napoleon as the enemy of all states and sovereignties outside France, and alliances were formed against his ambition and genius. Napoleon soon had arrayed against him the armies of Austria, Prussia, and Russia, and it was becoming evident that before long England would join the coalition. His expedition to Egypt began in May, 1798, and he accomplished the capture of Cairo in July. His fleet, however, was destroyed on August 1st by Nelson at the battle of the Nile.

Peace Overtures. There were domestic troubles in France meantime, and Bonaparte returned to take part in forming a new constitution. With some other leading Frenchmen, he established a new constitution, under which the Government of the country was invested in three Consuls. Napoleon was nominated First Consul for ten years. He now made overtures for peace to England and to Austria, and he endeavoured to convince these Governments that he was a sincere friend of peace. It is contended by some English writers that if Bonaparte's overtures had been accepted, an abiding peace might have been won for Europe.

France was still profoundly influenced by resentment for the attitude which most of the European monarchial states had adopted towards the French Revolution, and she believed she had reason to regard Europe in general as her enemy. Napoleon took command of an army, which he led through Switzerland, across the St. Bernard, into Italy; he occupied Milan, and defeated the Austrians at the battle of Marengo. Austria offered terms of peace by giving up the greater part of North Italy; a treaty with Germany followed in February, 1801, and the Treaty of Amiens, with England, in 1802. Napoleon was then elected First Consul for life, and set himself to work for the reconstruction of the whole civil constitution of France. She was, however, no nearer to peace than she had been before. Napoleon was possessed by the conviction that England felt for him an irreconcilable enmity, and the English believed that Napoleon was planning some treacherous attack upon them.

Three Great Battles. On May 18th, 1804, Napoleon assumed the title of Emperor of the French, and it soon became evident that a great European war was at hand. Napoleon appears at one time to have been maturing a plan for the invasion of England, but her naval superiority made this design futile, and he led his armies through Hanover, won a great victory over the Austrians at Ulm on October 15th, 1805, and on December 2nd following he won the great victory at Austerlitz over the allied Russians and Austrians. He had, during this campaign, inflicted defeats on the Prussian Army. Prussia, however, still held out, and got together a new army; but it was to little purpose, for Napoleon won another great victory at Jena. At last a peace was made by which Prussia had to surrender nearly half her territory. Napoleon sent an army into Portugal under General Junot, and another to Spain under Murat, who captured Madrid.

Napoleon made his brother, Joseph, King of Spain. Joseph had already been created by him King of Naples, but Napoleon thought it now more fitting to transfer him to the rulership of the defeated Spaniards. The Spaniards kept up a continuous rebellion, against which Joseph, who was a kindly-hearted and humane man, found himself unable to contend, and he soon withdrew from the troubles of Royalty to a life of peace.

The Retreat from Moscow. Napoleon endeavoured to carry on his conquests, but a new figure had arisen on the scene in the person of Arthur Wellesley, afterwards Duke of Wellington. He began by defeating Junot and other of Napoleon's marshals, and the event marked the opening of a change in his career. He took a fatal step by invading Russia with an army of 600,000 men, because it would not assent to his annexation of Holland and Westphalia. He won his first battle, which he followed up by taking possession of the city of Moscow. Here he met with unexpected resistance, for a vast fire broke out, destroying the greater part of the city and rendering a retreat unavoidable. The retreat from Moscow was one of his greatest disasters—it was the beginning of the end.

Napoleon returned to Paris to raise a new army, but the day of his greatness was over. He received a crushing defeat at Leipzig, and then began the invasion of France by the Allies. Wellington was now leading his army across the Pyrenees, and Napoleon, feeling that the game was over—at any rate, for the time—offered to abdicate in favour of his son. The offer, however, was not accepted, and he was compelled to make an unconditional abdication.

The Allies offered to confer upon him, on condition of his withdrawal from France, an empire of a somewhat diminutive order. He was to be created sovereign of Elba, with the title of Emperor. This arrangement Napoleon accepted on April 5th, 1814, as he had at the time no means of resisting. Outside France, he had aroused all Europe against him, and his enemies had him in their power. He had, therefore, to accept terms which practically made him an exile. But he soon began to make secret arrangements for a return to the scene of his Imperial power. He escaped from Elba with some followers in a little fleet of hired vessels, landed in France on March 1st, 1815, and received a rapturous welcome throughout the country, the army receiving him with undivided enthusiasm. The Empire was restored as by magic, and Napoleon once more entered Paris in triumph at the head of his army.

Waterloo. The coalition against him had in the meantime become relaxed in its cohesiveness, and when Napoleon returned to France, only a mixed force in Belgium under Wellington and a Prussian army commanded by Blucher, along the Rhine, were ready to oppose him. Napoleon gained a victory over Blucher, but lost some time before following it up. Napoleon then led his forces to attack Wellington, who had already defeated, at different times, most of the Emperor's ablest marshals, and he now had the advantage owing to Napoleon's want of promptitude in a decisive movement. With the help of the Prussians, who had joined him, Wellington won a complete and crushing victory over Napoleon on the Plains of Waterloo.

Napoleon, knowing that his last hopes were gone, fled to Paris, and, with the intention of seeking refuge in America, went to Rochefort: but, either changing his purpose or finding the project impracticable, he gave himself up as a prisoner to the captain of the British war vessel, the Bellerophon, and was brought to England, and from thence banished by the British Government to St. Helena. He arrived on October 15th, 1815, and there he spent the remainder of his life.

The Restoration of the Bourbons. When Napoleon left Paris after the defeat at Waterloo, Louis XVIII. entered it, and the family of the Bourbons was restored for the time to the throne. A decree was passed excluding for ever all members of the Bonaparte family from France. Louis XVIII. died in 1824, and was succeeded by Charles X., who distinguished himself only by his efforts to restore the absolute system of the old French monarchy. But the principles of the Revolution had spread too widely and deeply among the French people to admit of any return to the ancient systems. The settlement made at the Congress of Vienna by the victorious European sovereigns, with the object of maintaining the old-fashioned system of monarchy, was made with no regard to the development of human intelligence, the spread of education, and national sentiment. Charles X. tried to maintain his power by passing the Proclamation of Ordinances, announcing a new system of elections, restricting liberty of speech and publication, and abolishing the charter which the Bourbon family consented to accept on their restoration. The King also dissolved the Parliament which had but recently been elected as a protest against the tyrannical measures he was introducing. The result was that the people of Paris rose in armed resistance, and the King had no course left than to abdicate—on August 3rd, 1830. He died in exile.

Louis Philippe. Louis Philippe, the eldest son of the Duke of Orleans, was born on October 6th, 1773. When the revolution broke out and the Republic was established, he and his father joined the popular movement. He served in the wars of the Republic, but soon got into political trouble, and sought refuge in Austria, and afterwards in Switzerland, where he made a living as a teacher. He spent some years in the United States, and afterwards settled near London. On the restoration of the sovereignty in France, he was enabled to recover his estates, and on the abdication of Charles X. was raised to the crown. He was popular for a while, because he was believed to be a constitutional sovereign; but he disappointed popular expectations, and when public disappointment showed itself in constitutional fashion, he had recourse to the old measures of reaction—the dissolving of Parliaments, the suppression of hostile newspapers, the secret interference with trial by jury, and intrigues with foreign Governments. There was a rising against him in the February of 1848. He was forced to abdicate, and took refuge in England, where he died on August 26th, 1850. After his flight, a Republic was proclaimed. Among the rising figures in the new Republic was that of Louis Napoleon, the son of Louis Bonaparte, the great Emperor's brother.

Louis Napoleon. Louis Napoleon had lived in exile and had written and published some military and political treatises. By the death of the Duke of Reichstadt, only son of Napoleon I., he became the head of the family. He made two unsuccessful attempts to create a Napoleonic restoration, and for the second he was sentenced to perpetual imprisonment in the fortress of Ham. He escaped after five years and came to England. When the revolution of 1848 broke out in France, he returned, and was elected a member of the Constituent Assembly; he afterwards became a candidate for the Presidency, and was elected by an immense majority. For a time he played the part of a constitutional and republican chief magistrate, but his ambition sought a higher sphere and more complete authority, and he succeeded in obtaining the confidence of the Army. On

December 2nd, 1851, he abolished the existing constitution, so far, at least, as it prevented the creation of a dictatorship. This was an open act of military power, but it appeared to have had the support of the country, for when the vote was taken, Louis Napoleon was re-elected President for ten years by a suffrage of over seven millions.

The Empress Eugénie. He soon assumed the title of Emperor, and was again supported by the country in general. He now made it his work to recommend himself especially to the army, the democracy, and the clergy. He insisted on the right of peoples to chose their own rulers, but he imposed the severest restrictions on the liberty of the Press. On January 29th, 1853, he married Eugénie de Montijo, a Spanish countess of remarkable beauty, who made a brilliant figure at the Imperial Court, and who lived to see the fall, to share the exile, and to kneel by the grave of her husband. The policy of Napoleon throughout seems to have been directed to propitiate the popular vote and to conciliate the Army. He undoubtedly effected much good work towards the improvement of the cities and towns of France, and established Treaties of Commerce with many foreign states. The commercial treaty with England was prepared by Richard Cobden for England and by Michel Chevalier for France. He exerted all his power towards the repression of republican opinion and all independent opinion in the Press or on the platform. He formed military alliances with other European states; and with England, Sardinia and Turkey he helped to carry on the Crimean War against Russia. He also carried on a successful war against Austria, which did much towards the emancipation of Italy.

Louis Napoleon and Mexico. Most unfortunate was his attempt to convert the Republic of Mexico into an empire under the rule of the Archduke Maximilian of Austria. This began as the result of many just complaints made by the English, French, and Spanish Governments of the ill-treatment of foreigners in Mexico, and the non-payment of arrears due to foreign fund holders. The three Governments resolved to enforce their claims; but Louis Napoleon's project for the creation of an Empire in Mexico was disapproved by the English and the Spanish Governments. The French Emperor carried it on alone and the Archduke Maximilian entered Mexico as Emperor under his protection. The Mexicans held out with irrepressible resistance and the Government of the United States came to their aid, supporting this action by the terms of the famous Monroe doctrine, and Napoleon's Government found it necessary to withdraw their troops.

Maximilian carried on the resistance to his Mexican opponents, and sanctioned the execution of several Mexican generals in the service of the Republic who had maintained the cause of their country in arms. When Maximilian's attempt to found an empire thus utterly failed, he was, in his turn, tried by court-martial, ultimately condemned to death, and shot.

War with Prussia. Louis endeavoured to recover his lost prestige by finding a pretext for quarrelling with Prussia, against whom he declared war in July, 1870. That war proved the crowning failure of his policy. The Prussians won victory after victory, and at last occupied Paris, Napoleon III. being captured and held as prisoner until the settlement of that Peace which brought about the formation of a new French Republic. In March, 1871, he came over to England, and lived there with his wife at Chiselhurst, in Kent, where he died on January 9th, 1873. Their son, Eugène Louis, had served in his father's army during the fatal war of 1870, and afterwards accompanied his parents to England. He served as a volunteer with the English forces in Zululand in 1879, and lost his life in the campaign.

The new French Republic was founded under conditions which might have seemed hopelessly discouraging. The enemy was still in possession of Paris and a great part of the country; and, further, a great socialistic revolt was springing up among the French people, chiefly among the population of the cities. The Commune was actually proclaimed, and some fearful riots took place, among which several French generals who had fought for their country against the Germans, and were now fighting for the Republic against the Commune, were done to death. The Archbishop of Paris, Monseigneur Darboy, was murdered. The Communists held Paris for a time, and when this became impossible they burnt down many of the great public buildings. The Republic conquered in the end, and severe punishments were inflicted.

The New Republic. The President, M. Thiers, had to undertake with the opening of his presidency the task of concluding peace with the German invaders and bringing the civil war to an end. Both tasks were accomplished, and the Republic began its work of peaceful civil government. But even in the Constitutional Assembly there was a still strong monarchial party; indeed, two parties—one in favour of restoring the old Legitimist dynasty and the other supporting a restoration of the Orleanist dynasty. Thiers, although a monarchist at heart, maintained that a new monarchy was impossible at the time, and allied himself with the Republicans. Leon Gambetta, a great democrat and orator, who, during some of the recent troubles, had been in all but name Dictator of the country, maintained the cause of the Republic, and the Republican party had a complete victory. Thiers died during the course of the electoral struggle which decided the victory. The Third Republic was founded with a succession of elected presidents, for a fixed period of years, to be its presiding magistrates. That Republic has already lasted much longer than either of the two which preceded it, and there does not at present seem any indication that the public mind of France is likely to turn with favour again to any project for the foundation of a Monarchy or an Empire.

MANY TELEGRAMS ON ONE WIRE

Duplex and Quadruplex Working. Various Methods of Transmission. Sending Two or Four Messages Simultaneously on one Wire

Group 10

TELEGRAPHS

7

Continued from page 5178

By D. H. KENNEDY

It is safe to say that nothing excites the wonder of the young telegraphist more than duplex working, the system which enables messages to be sent simultaneously in opposite directions on a single wire. Most of the English circuits are worked on what is called the *differential system.* Let us approach the subject from familiar ground.

Consider a single-current circuit as shown in **30**, page 5067. How can we modify it so as to enable it to be used for duplex working? As we wish to be able to receive a signal at the same time as we are sending, it is clear that we must alter the position of our relay so as to include it in the line circuit. We may do this by connecting No. 3 terminal to No. 1. and No. 2 to earth. Now we find that our own signals affect our relay, and we come to the real crux of the problem—that is, how can we signal through our relay without affecting it? For this purpose the relay is arranged with differential windings. First, we must adjust the brass straps so that both are connected across between Ⓓ and U. Now rearrange the circuit connections as shown in **45**.

Duplex Working. Now we have one winding of the relay Ⓓ to Ⓤ included in the line circuit, and currents sent through it would, as before, reproduce our marks. A little consideration will, however, enable us to see that we can arrange to send through the winding U to D a current of the same strength as that in Ⓓ to , so that the relay armature will be unaffected To do this we must connect the bridge of the key to D by a suitable resistance—that is, a resistance equal to that of the line, the distant apparatus, and our own galvanometer.

The Artificial Circuit. The circuit is now as shown in **46**. The part between U, D and the key may be called the *compensation circuit* or *artificial circuit,* and we see that our signals to the distant station pass through our own relay, but leave it entirely unaffected Now we extend our considerations to both stations, arranging them similarly. On examination we find, first, that each station can signal to the other one without affecting his own apparatus. Secondly, we must consider what changes take place when, the key at A being already held down, that at B is also depressed. For this purpose we take another diagram [**47**], omitting everything except relays and batteries.

The circuits may be shown as three rectangles, X, Y and Z; and since X was made equal in resistance to Y, and Z was also made equal to Y, all three are of equal resistance. The current from battery A divides equally between X and Y, as shown by the single-headed arrows. Similarly, the current from B, which is of the same strength as A, divides equally between Y and Z, as indicated by double-headed arrows. As a result of the joint action of A and B, the current in the line circuit Y is double that in either of the compensation circuits X or Z. As a consequence the Ⓤ to Ⓓ winding of each relay is traversed by current double the value of that in the compensation circuits, so that both "mark." Each station can therefore signal through his own relay without affecting it, and

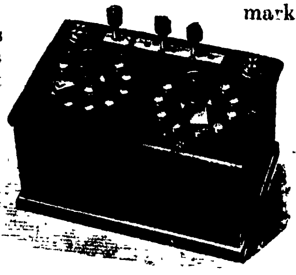
DUPLEX WORKING

45-48. Evolution of the Duplex from the Simplex

49. Single-current sounder circuit with relay and switch for Duplex or Simplex working

50. Connections of D pattern rheostat can energise the distant relay whether the distant station battery is in or out of circuit. To facilitate adjustment, the galvanometers are also differentially wound, and the interpretation of their deflections has been explained in the practical section.

Battery Resistance. It has been stated that when both batteries are introduced into the line circuit the current is doubled. In order that this may be quite true, the doubling of the electromotive force must take place without any alteration of the total line resistance. The batteries, however, may have considerable resistance, so recourse is had to the expedient of introducing resistance coils, which take their place in the circuit alternatively with the battery. A complete skeleton diagram is given in **48**.



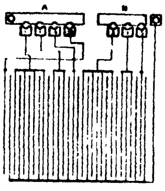
51. RHEOSTAT—D PATTERN

Duplex and Simplex Switch. On many circuits, especially provincial, it is necessary to work duplex only during the busy hours. To economise battery power a switch is provided by means of which the connections can be altered as required.

Fig. **49** is a diagram of the arrangement, and shows also the usual positions of the various parts on the instrument table. To add to his memory stock the student should take the switch terminals as times on a clock, beginning at 8 a.m., thus:

8 o'clock *split* of relay
10 ,, *three*
12 ,, *two*
2 ,, *rheostat*
4 ,, *one*
6 ,, *zinc* of battery

The italicised words can easily be strung together and retained as a mnemonic.



52. CONDENSER CONNECTIONS

Rheostats. Variable resistance under this name are always used for the artificial circuits. They are made up of resistance coils [see page 7891], connected so as to allow of any required resistance within certain limits being introduced into the circuit. The latest pattern, known as the D Rheostat, is shown diagrammatically at **50**, while **51** shows its external appearance.

Double-current Duplex. To alter a circuit from single-current to double-current duplex, it is necessary only to introduce a double-current key and to remove the single-current key and the battery resistance block. We proceed, therefore, in the direction of simplification, and all new duplex circuits in the Post Office administration are made double-current.

Long Circuits. For long circuits, however, it is necessary to modify the artificial circuit. When the line exceeds 100 miles, the difference between the capacity of the long and comparatively thick line wire and the negligible capacity of the few coils of small wire in the artificial circuit becomes sufficiently marked to interfere with the signals. Artificial capacity is therefore introduced in the shape of condensers.

A *condenser* is a development of the Leyden jar. For telegraphic purposes it is made by arranging a large number of layers of tinfoil and paraffined paper. Odd-numbered tinfoils are then connected together to form one surface, and even-numbered tinfoils to form an opposing surface.

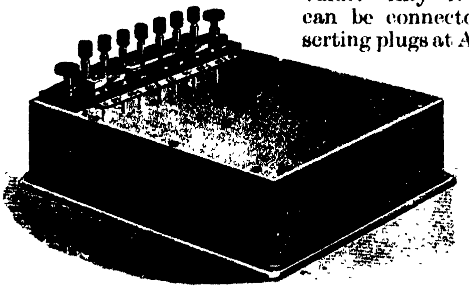
It was pointed out on page 5178 that the capacity of lines varied as their surface, and inversely as their distance from the earth.

In the condenser artificial circuit, one metallic surface represents the line and the other represents the earth, and by reducing the distance between the surfaces to the smallest practical limits, the necessary amount of surface to provide a given capacity is surprisingly small.

The capacity of an ordinary aerial wire is about ·015 microfarads per mile.

Two microfarad condensers are made, having dimensions 7½ in. by 4½ in. by ¼ in., so that in this small compass we have capacity representing 133 miles of line. For use in the artificial circuit, the condenser must be adjustable.

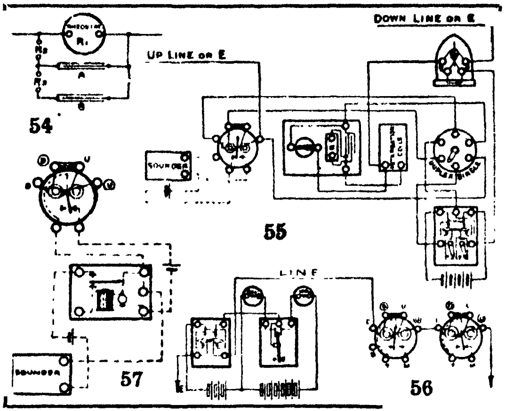
The Condenser. Figure **52** shows the internal arrangement of a 7¼ microfarad condenser, and **53** its exterior. C and D [**52**] are the terminals. The parallel lines represent layers of tinfoil, and the intervening spaces layers of dielectric. One surface of each section is connected to D, the remaining surfaces being each connected to a brass segment marked with the appropriate value. Any required number of these can be connected to terminal C by inserting plugs at A or B. It will be observed, however, that there is a break between A and B. This is for the purpose of allowing what is called a *retardation coil* to be inserted.



53. CONDENSER—7¼ MICROFARAD

The need for this will be seen if we consider the simultaneous charging of a long line, and the corresponding artificial circuit. The resistance of the line limits the maximum value of the charging current, and so lengthens the time necessary for the charge to reach its maximum.

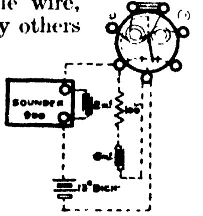
Consider **54**, which represents the artificial circuit. R is the rheostat, and R2 and R3 are retardation coils. The section A of the condenser is charged through the resistance R1, while section B is charged through both R1 and R2. A therefore corresponds to the near portion of the line circuit, and B to the more distant portion. Now if R2 and R3 were not present to slow down the rate of charging the condensers during the first instant of the charging process, the current to charge the artificial circuit would greatly exceed the current charging the line circuit, and would therefore affect the relay in the way we wish to avoid.



54. Arrangement of artificial circuit 55. Connections of double-current duplex. 56. Principle of Diplex system 57. Quadruplex—B side—uprighting sounder

Figure **55** is a diagram of the complete connections of a double current duplex. The student who has memorised the preceding examples will not find this difficult. In the mnemonic system, the right-front terminal of the key becomes No. 4, the rear-middle terminal No. 3, and the left-front may be called 0. The switch terminals will now read, "split, 3, 2, rheostat, 1, 0."

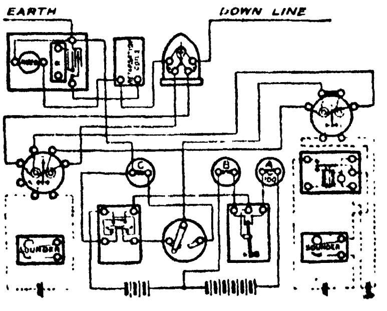
Quadruplex Working. The success of the duplex system led to further efforts to enhance the traffic capacity of a single wire, and although it had been suggested by others at an earlier date, it was Edison who first produced a practical system, in 1874. The main advance upon previous knowledge consisted in devising the diplex system, which enables two messages to be sent simultaneously in one direction.



58. QUADRUPLEX CONDENSER—B SIDE

Diplex Working. This is accomplished by providing, at the receiving end, two relays, one polarised and one non-polarised, connected in series to the line, while at the sending end there are two keys connected in series. One of them is a reversing key, similar in principle to the double-current key, while the other is an increment key.

It will be kept in mind that a polarised relay is affected by the direction of the current. The non-polarised relay is affected by currents of sufficient strength, irrespective of direction, but it is in this case specially arranged so that it requires a current three times as great as that used normally for working the polarised relay. Figure **56** illustrates the principle.



59. QUADRUPLEX UP-OFFICE CONNECTIONS

The relay A is worked by the key A, exactly as in ordinary double-current working. Only one-third of the available battery power is being used, and the non-polarised relay B is unaffected. Immediately the key B is depressed, the strength of the current is trebled, and relay B is energised. The increase of current causes, of course, no inconvenience to the A set, as the *direction* of the current is still controlled by the A key.

Now if we imagine this arrangement modified for duplex working by using differential relays and an artificial circuit, we at once jump to the conception of the quadruplex system.

Diplex Difficulties. Such difficulties as are experienced in quadruplex working are connected with the diplex principle, so it will be well to dispose of them first.

So far it has been tacitly assumed that under all circumstances a current, either strong or weak, is flowing in the line. Consequently key B must be arranged so that it makes contact with the larger battery before breaking with the smaller. For the smallest practicable space of time the two ends of the larger section of the battery are connected by the increment key.

Spark Coil. To prevent the sparking which would ensue owing to the heavy current produced under such circumstances, a spark coil of 100 ohms resistance is inserted between the positive pole of the battery and the increment key. This removes any possibility of trouble from the variation in the strength of the current.

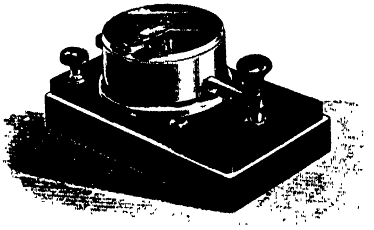
When the B key is properly adjusted, the A signals are good. We have still to consider how the working of A key affects the B signals.

As the A key reverses the direction of the current, it is evident that for an instant we have zero current, and if this occurs in the middle of a signal on the B instruments there is a tendency to splitting which has to be specially dealt with.

Uprighting Sounder. A very ingenious method for overcoming this difficulty was devised by Mr. Gerritt Smith, and is illustrated in **57**, in which the non-polarised relay, the uprighting sounder, and the reading (ordinary) sounder are shown.

It will be noticed that the relay is arranged so that it normally closes the circuit of the uprighting sounder, which in turn closes that of the reading sounder. In the ordinary case of relay and sounder, considered at page 5067, the sounder is not actuated until the relay tongue travels over to the marking stop. In this case, however, we see that immediately the relay tongue *leaves* the right-hand stop the reading sounder is affected.

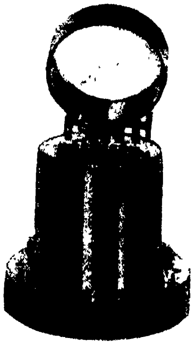
The important fact, however, is that under the influence of a signal current the tongue lies on the left stop. If any break in that signal occurs, *unless* it is so long as to allow the tongue to travel back to the right-hand side, *no* break in the signal on the reading sounder occurs. In practice, good working is easily attained.



60. QUADRUPLEX INCREMENT, OR B KEY

Condenser B Side. Recently, however, it has been found possible to dispense with the uprighting sounder, and its battery, by taking advantage of the use of a condenser [58].

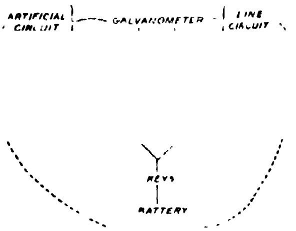
The reading sounder has coils of 1,000 ohms resistance shunted by a coil of 9,000 ohms (joint resistance 900 ohms). Its terminals are connected to a 2-microfarad condenser. A 100-ohm resistance coil and a half-microfarad condenser are joined across the relay contact terminals to prevent sparking. It will be seen that in this device the capacity effects which in the line caused trouble are used to good purpose. The sounder can now be worked directly from the relay, and any small breaks in the signals are bridged over by the discharge from the condenser.



61. NON-POLARISED RELAY C

The A key is similar to that shown in **12**, page 4607, but it has no "send and receive" switch, and consequently the middle-rear terminal provided in a double-current key is not needed here. Figure 60 illustrates the B or increment key. The A side relay is of the Post Office standard form already described on page 5067. On the B side a larger instrument, known as a non-polarised relay C, is used, as shown in **61**. The armatures are placed obliquely between the pole-pieces, and currents in either direction tend to attract them against the tension of the spiral spring. Each armature is divided into two sections, which are brazed together. This magnetic separation tends to rapidity of action. Differential winding is employed, and the terminals are marked in the same manner as the Post Office standard relay.

Connections. Figure **59** is a diagram of a quadruplex upstation, showing all the "connections," as it is usual to call them. The student who has given some reflection to the arrangement of the duplex will quickly see the system followed in arranging the "quad." He will see that the current divides at the non-polarised relay, and follows in succession through the A relay and the galvanometer. The arrangement can, in fact, be symbolised in the manner shown in **62**.



62. ARRANGEMENT OF MAKING UP QUADRUPLEX STATION

The two-way switch between the keys is the line and earth switch referred to in the last section as being used during the balancing process. When turned to the right it cuts off the battery to facilitate adjustment at the distant station. At the same time it substitutes the resistance coil shown connected to its right terminal. Its value is made equal to the resistance of the battery and spark coil combined.

Current Values. The current strengths required for quadruplex working are, for the A side, 15 milliamperes, and for the B side 45 milliamperes. This gives a ratio of three to one between the B and A currents, and practice has shown this to be the most suitable value. Bichromate cells are used for the main and local batteries. For the uprighting sounder and the relaying sounder three cells each are used. When the uprighting sounder is substituted by the condenser method of arranging the B side a battery of 13 bichromate cells is used for the local circuit.

Although the quadruplex came to us from America, much of its present good working is due to subsequent English improvements, and there are now over 500 sets at work in the United Kingdom.

Manual versus Automatic Systems. All of the systems so far dealt with have been of the manual order—limited as to speed by the expertness with which the operator could, letter by letter, form the signals. We shall now proceed to discuss various systems in which automatic methods of making the signals at high speed are employed. It should, however, be noted that in the manual system the three operations of forming the signals, transmitting the currents, and transcribing the signals are performed simultaneously, whereas, in the automatic systems they must be performed seriatim. These facts have exercised a strong influence in favour of manual systems and continue to do so to such an extent that in this country the manual sets outnumber the automatic, so far as the Post Office is concerned, by 25,492 to 585.

It can easily be seen that where towns separated by, say, 500 miles are concerned, the inducement to save the expense of additional lines by using automatic methods is considerable, but even the longest circuits in the United Kingdom are worked manually.

THE LIFE NOT WORTH LIVING

The Degradation of the Bee-hive Conception of Society. Is an Ant-hill Worth While? The Supreme End of Society is the Development of Personality

Continued from page 5100

By Dr. C. W. SALEEBY

WE are now quite ready to accept the doctrine of Carlyle: "Man is created to fight; he is perhaps best of all definable as a born soldier; his life 'a battle and a march,' under the right general. It is forever indispensable for a man to fight; now with necessity, with barrenness, scarcity, with puddles, bogs, tangled forests, unkempt cotton; now also with the hallucinations of his poor fellow-men." We have seen how, even in the spiritual type of society which we have imagined, this born soldier, man, will have to fight with and ultimately command Nature ("only by obeying her"), and, still more, must ever fight against the weaknesses of his own nature. There will be room for the soldierly qualities until the end of time.

The Spiritual Type of Society. But now we must consider from another point of view this spiritual type of society, in which military and even industrial warfare will have ceased, and must endeavour to express its characters in strictly sociological terms—that is to say, in terms of the relation between individuals and society. Here we can certainly find no better guide than Professor Höffding. In a recent lecture to the Sociological Society in London, the great thinker of Copenhagen thus expresses the sociological ideal ("Sociological Papers," 1905. Macmillan):

"If the single individual in developing itself in its own peculiar way gives the best possible contribution to the whole life of society, and if, on the other hand, society is organised in such a manner that a free and full development is possible for all individuals, then we are approaching to the ethical ideal."

In the same great thinker's "Philosophy of Religion," which is surely the greatest work of the greatest thinker now alive, we find the same ideal well expressed (English Translation, Macmillan, page 359):

"Self-assertion is no longer exhibited as the opposite of love. For magnanimity possesses strength enough to support not only the individual's own life, but also the life of other men. And the highest virtue is justice, in which both self-surrender and self-assertion are included. *The ideal is a kingdom of personalities, in which each individual unfolds his personality in such a manner that in this very act he helps others to unfold their own.* This conception offers free scope to all those ethical elements fostered by Christianity which are of lasting value." The italics are ours.

The Four Kinds of War. At present, observe, even though we hear less of military warfare, we hear only too much of internecine warfare within the society itself. That famous old Dutch writer, Grotius (1583-1645) distinguished four kinds of war—the individual against the individual, society against society, society against the individual, and the individual against society. It is the two latter kinds of which we hear so much to-day, and we see that in the ideal state as pictured by Höffding these have vanished. The ideal is only the sociological expression of Spencer's great discussion of the ultimate reconciliation of egoism and altruism.

We must go back to classical English, however, for the finest expression of our ideal, which Spencer and his followers have detailed in these scientific times. Altering its application, we may remind ourselves of the fine phrase "whose service is perfect freedom." In the ideal state of society we shall see no more of any of the four kinds of war which Grotius distinguished. Each man's service of his fellows will be compatible with his own perfect freedom. In a word, the social ideal is anarchy—the higher anarchy. To this we may hope to return.

The First Fact about Society. We have now discussed war as fully as our space will permit. We have seen in it a means which has been employed in the organisation and development of society. Even the wars of religion, perhaps, may show to the seeing eye the "soul of good in things evil." We have refuted the popular doctrine that men decay unless they fight, and unless they fight with fist or gun; but have admitted that man must always struggle or strive, and we have endeavoured to point to the direction which the evolution of human strife is taking. Now, having considered the fundamental social institution—marriage and the family—and this great factor of struggle between and within societies, we must turn our attention to the larger outlines of the constitution of society, and though we may begin with far-away biology, we shall find ourselves, before long, grappling with the most urgent political question of the hour.

The fundamental fact of sociology, which constitutes the *differentia* of our science, is that society is not an aggregate but an organism—not a heap of bricks, but those bricks built up into a building. Thus, the problems of society are not simply the problems of the individual multiplied by the number of individuals within the society. This is the first fact which we have to study in regard to the constitution of society. It is fundamental because it is true of all societies, and is not affected by forms of Government. It is true of a democracy or a monarchy, of a communistic or an individualistic state; and this study of society as an organism yields us facts and principles of universal application by which we may be enabled to judge the relative worth of such varying forms of external constitution. Similarly, for instance, the biologist has to study such markedly contrasted organisms as an oak and a horse; but though the external constitution of the two is so different the fundamental fact of the two is the same—the interdependence of the unit and the whole.

St. Paul as a Sociologist. The idea of comparing society to a living creature is very old and very celebrated; and the significance of the comparison has been found to grow with the growth of any sound sociology. If we go back even to Socrates, the immortal founder of the supreme science of ethics, we find his pupil Plato, to whom we owe all that we know of the teaching of Socrates, conceiving of society as an organism. A few centuries later, we find St. Paul, who was a philosophical genius of the highest order, repeatedly employing the image in question. Through the whole of his epistles we find him comparing the early Christian Church to a living body, and using the comparison as the basis of many valuable arguments. The present writer thinks that sociologists have not adequately recognised the place of St. Paul in the history of this subject. We may quote from the twelfth chapter of the Epistle to the Romans a typical instance of St. Paul's employment of this figure: "For as we have many members in one body, and all members have not the same office: so we, being many, are one body in Christ, and every one members one of another."

From the same age and from Rome itself, we may quote the classical fable of the rebellion of the rest of the body against the privileges of the stomach: "There was a time when all the body's members rebelled against the belly." Shakespeare uses this with great skill in "Coriolanus," Act i. Scene 1, where he makes Menenius employ this argument against the discontented citizens, saying. "The senators of Rome are this good belly and you the mutinous members," and contemptuously calling one of the complainants who was prominent but contemptible, "the great toe of this assembly."

In more recent times we have that remarkable genius, Hobbes, who wrote the great book "The Leviathan," in which, as the title suggests, he compares the State to a huge animal.

The Social Organism. But it is not until the time of Herbert Spencer that we find this ideal worked out with adequate knowledge. For one thing, his predecessors had not known enough about the structure of individual organisms to enable them to make anything but merely general or poetic comparisons. When Spencer came to the subject, certain great facts had lately been discovered, and he used them like the consummate genius that he was. The cell theory had lately been advanced. Fortunately, there is no need for us to discuss its meaning here, since the reader has been well prepared by other courses. In 1850, then, in his first book, "Social Statics," and notably in his great essay on "The Social Organism," published in 1860, and now to be found in the first volume of his republished essays, Spencer introduced that phrase "the social organism"—conveniently contrasted with the individual organism—which, like so many of his ideas and phrases, is now employed every day as an instrument of argument and of thought.

A society of electrons constitutes an atom, as we have lately been studying, a society of atoms a molecule, a society of molecules a living cell, a society of cells an individual organism, and a society of individuals a social organism.

A Great Man's Great Error. As we pass upwards in this scale, and reach the three living units which constitute its last three terms, we find illustrated more and more abundantly that great principle which Milne-Edwards, the French student, called the "physiological division of labour"—the differentiation of function and of structure, so that the part becomes not merely or not at all an end in itself, but merely a servant of the whole. We have seen how completely this was recognised by St. Paul, and in the Roman fable, as true of the individual organism and of the social organism. We now know that it is absolutely true of the cells—with nucleus, centrosome, and so on—which constitute the units of all individual organisms; and if we recognise the family as the unit of all higher societies, we can recognise the physiological division of labour in it also, only it is now more than physiological and has become sociological: the mother has one function and the father another.

Only very briefly here need we consider the working out of the last and most important part of our analogy—the analogy expressed by Hobbes, though with many fundamental errors, when he speaks of "the great leviathan called a Commonwealth or State, in Latin *civitas*, which is but an artificial man." The last word in the whole world that is true here is the word artificial. Both Plato and Hobbes fell into this fundamental error—that societies are artificial structures "to be consciously put together by men, just as a watch might be."

Societies are Natural and Inevitable. As Spencer points out, they thought that "what is in its nature an organism is in its history a machine!" We see exactly the immeasurable difference between Spencer's conception—the conception of the author of the idea of *natural* evolution—and that of his predecessors when we discover that Hobbes "even goes so far as to compare the supposed social contract, from which a society suddenly originates, to the creation of a man by the Divine fiat." We now know that man was not so created—nor any societies. We utterly reject the hypothesis of manufacture in both cases, and we believe it to be true of man as well as societies that "constitutions are not made but grow." Furthermore, the growth of societies is as inevitable a consequence of the laws of Nature—which, as we must never forget, include the laws of human nature—as is the growth of individual organisms. In Spencer's words: "While each citizen has been pursuing his individual welfare, and none taking thought about division of labour, or conscious of the need of it, division of labour has yet been ever becoming more complete. . . By steps so small that year after year the industrial arrangements have seemed just what they were before—by changes as insensible as those through which a seed passes into a tree—society has become the complex body of mutually-dependent workers which we now see. And this economic organisation, mark, is the all-essential organisation. Through the combination thus spontaneously evolved, every citizen is supplied with daily necessaries; while he yields some product or aid to others. That we are severally alive to-day, we owe to the regular working of this combination during the past week; and could it be suddenly abolished, multitudes would be dead before another week ended."

Individuals and Societies. We need not now concern ourselves with the comparisons of Hobbes, some of which are very good and some very bad. Nothing could be worse than his comparison of the sovereignty to "an artificial soul as giving life and motion to the whole body." On the other hand, this is good: "Councillors, by whom all things needful for it to know are suggested unto it, are the memory. . . . Concord, health; sedition, sickness; and civil war, death."

In the light of modern knowledge we may venture to quote our own comparisons: "The governing mechanism of a society corresponding to the nervous system; the manufacturers to the glands, permanent officials to the bones, traders to the circulatory apparatus, soldiers and scavengers to the white blood cells—and so on."

But now we come to that which gives the whole analogy its value—that for which we are lastingly indebted to Spencer. His summary of the *points of resemblance* between the individual organism and the social organism is well worthy of quotation, especially as it can only be obtained in a very expensive volume. We give it here; and then we would ask the reader, before proceeding any further, to see whether he cannot anticipate for himself the equally important question of the *points of difference*.

Herbert Spencer's Comparisons. The points of similarity between societies and individual organisms are these:

1. "That, commencing as small aggregations, they insensibly augment in mass, some of them eventually reaching ten thousand times what they originally were.

2. "That, while at first so simple in structure as to be considered structureless, they assume in the course of their growth a continually increasing complexity of structure.

3. "That, though in their early, undeveloped states there exists in them scarcely any mutual dependence of parts, their parts gradually acquire a mutual dependence which becomes at last so great that the activity and life of each part is made possible only by the activity and life of the rest.

4. "That the life of a society is independent of, and far more prolonged than, the lives of any of its component units, who are severally born, grow, work, reproduce, and die, while the body-politic composed of them survives generation after generation, increasing in mass, in completeness of structure, and in functional activity."

The Difference between Individuals and Societies. It is to be hoped that the reader has anticipated what we are about to say. At a certain point the analogy between the individual organism and the social organism breaks down utterly, and the value of the analogy lies in its demonstration of the point of difference. There are other points of difference discussed by Spencer, but they are relatively trivial; there is only one which is vital. We recognise it directly we ask ourselves the end or object in either case. The object of the individual organism is *its own life*. Let the reader take his own case. All the cells and parts of his body have no meaning, purpose, or value as ends in themselves; they are means merely to one end—*his* life. He cares nothing for any part of his body except as it ministers to his well-being. "In washing my hands I write an indistinguished *finis* below the history of millions of my cutaneous cells; yet I never waste another thought on them. *I* prefer my hands clean, and there's an end on't." We may turn again to the Bible for the supreme expression of this truth—the truth that no part of the body is of any worth or meaning except as it serves the self: "If thy hand or foot offend thee, cut them off and cast them from thee. . . And if thine eye offend thee, pluck it out and cast it from thee." The hand, the foot, the eye have no claims on their own account, and may be destroyed—nay, must be destroyed—if they do not serve their owner.

Society has no Self. And here is where the analogy breaks down. We know what we mean by the welfare of the self, but what do we mean by the welfare of the State or body-politic? Society or the State has no *Self*. Says Spencer: "It is well that the lives of all parts of an animal should be merged in the life of the whole, because the whole has a corporate consciousness capable of happiness or misery. But it is not so with a society, since its living units do not and cannot lose individual consciousness, and since the community as a whole has no corporate consciousness. This is an everlasting reason why the welfares of citizens cannot rightly be sacrificed to some supposed benefit of the State, and why, on the other hand, the State is to be maintained solely for the benefit of citizens. The corporate life must here be subservient to the lives of the parts instead of the lives of the parts being subservient to the corporate life.

This conclusion of Spencer's is absolutely in accord with the fine expression of the social ideal which we lately quoted from Professor Höffding. That ideal fully recognises that the welfare of the State, unless it mean the welfare of its individual citizens, is nothing. "Only in the consciousness of individuals can the value of life be experienced." Life is personal or nothing—human life, that is to say. A few chapters ago we alluded to a contrast which will serve us here.

Man and the Beehive. In our brief attempt to cover an infinite subject we have been able merely to allude to that department of it which we may call Comparative Sociology. This study is only in its infancy, even though a good deal of attention has lately been paid to the societies of the social insects. Yet even already, as it seems to the present writer, we may learn a lesson from the beehive.

In this case the evolution of society has taken a course of its own. Life is no longer personal life, but communal life. In the beehive the individual unit is of no importance as an end in itself, and the same is true in the ant-hill. Neither of these institutions will give anything for our doctrine that "only in the consciousness of individuals can the value of life be experienced." The beehive does not care a straw for the consciousness of individuals. The individual worker or drone is of just the same importance to it as a cell of your skin is to you. When the cell has done its work you wash it off and cast it to the drains. Similarly, when the individual of the beehive has outlived its usefulness, it is quietly made away with, just as savage tribes make away with their old people. The beehive shows us the analogy between the individual and the social organism carried out to the uttermost. The welfare of the individual is naught here as compared with the welfare of the State. The analogy that breaks down so signally in the case of human society holds here all along the line, and Spencer's "everlasting reason" is null and void.

Beyond a doubt, the consequence of the subordination of the individual to the society achieves the end for which it is compassed, and there can be little doubt that the same would be true in human society. In coming years, it seems, we shall be making the experiment, as if the whole of the history of life, including the life of the bee, did not already include a record of this experiment.

Life at the Level of the Ant-heap. In general, life obtains what it strives for. In this case the object is the security and stability of the society. To this object the individual is ruthlessly sacrificed, and this object is attained. The ant-hill and the beehive are typical instances of social stability and efficiency. They can hold their own against other societies, and they have persisted for millions and millions of years. Bees and ants, be it remembered, are not even vertebrates; they are mere *Insecta*, and had their origin before even the earliest fishes, and they thrive to-day.

But what is it all worth ? The whole existence of such a society, where the individual is nothing, is itself nothing. What is lost if the ant-heap be destroyed ? Simply an ant-heap—simply a living machine which had sacrificed everything else, everything that makes life worth living, to the mere maintenance of a life that was not worth living. No more horrible prospect can be conceived for human society than its degradation to the level of the ant-heap or the beehive—a level which, despite its beauty of organisation and its success, we will yet call degraded. Estimate it in terms of worth, estimate it in terms of ethics, in terms of consciousness, and it is naught. It is merely an animated machine which has sacrificed to life all that makes life worth living.

The Worth of the Individual. Yet, again, what do we find in the society which has completely carried out the analogy between the individual and the social organisms, in which the individual is not an end in itself any more than the cell of the reader's epidermis is an end in itself ? If such a state of things were to lead to something higher, then, though we might deplore it as an end, we should welcome it as a means to the higher end. What, then, is the condition of such a society in relation to progress ? The answer is that the constitution of such a society involves the utter destruction of all the factors of progress. In such a society there is no place for individuality, character, or genius. It will burn or hang or poison its genius as surely as the Athenians poisoned Socrates, and it will never advance an inch. Such a society lives only in name ; it is a clever and efficient machine, but it is as essentially and spiritually dead as the engine of a motor-car. Men and women, living personalities such as ourselves, can pronounce no other verdict upon it. Life is either a matter of personality or a stage towards the development of personality—or else it is mere "putrefaction of the dust":

> "A tale
> Told by an idiot, full of sound and fury,
> Signifying nothing."

Society is More Than an Efficient Machine. The society, then, in which the welfare of the individual is no end in itself, in which individuality and personality are criminal nuisances, such a society may be as efficient as a beehive and as persistent as the insects; but it has said to itself, "Thus far and no further," and it is as dead as any steam-engine. Worse, indeed, is its state, for there is no spectacle so lamentable as that of life, whether insect life or human life, which has thrown away the substance for the shadow—the society wherein men and women toil for that which is not bread merely in order that the social organism may be an efficient machine, military or industrial.

It now remains for us to ask ourselves the conditions under which we may hope to realise the ideal expressed by Höffding. The beehive and the ant-heap show us the perfect fulfilment of the first half of that ideal. "The single individual, in developing itself in its own peculiar way [cf. the unsexed worker-bee], gives the best possible contribution to the whole life of society." But the other half of the ideal, the consecration of the "whole life of society" to the worthy, full and free development of each individual—this has been made for ever impossible.

How is it to be made possible for us ?

Continued

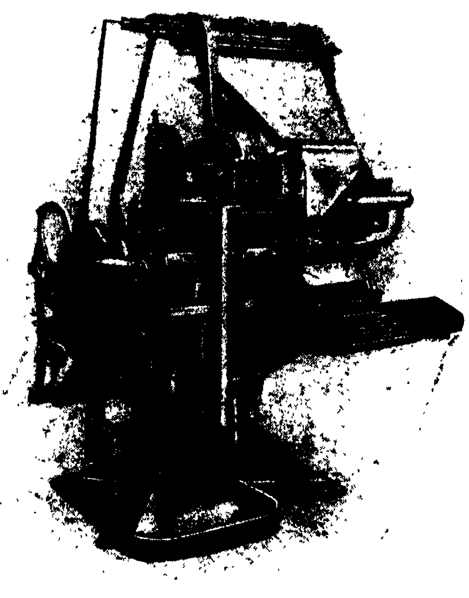
A MARVELLOUS MACHINE

The Linotype and Monotype Machines. How they Cast and Set Up Type. The Furniture of the Composing-room

Continued from page 5159

By W. S. MURPHY

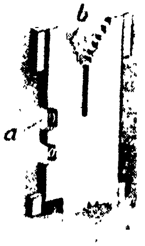
DURING the latter half of the nineteenth century, when machinery was revolutionising trades formerly considered impregnable to the cunning of the inventor, the compositor, secure in the belief that type-setting required a combination of hand and eye, foresight and judgment only possible to the human brain, viewed the efforts of mechanics to invade his province with amused indifference. Invent a machine that can think, and you will make a mechanical compositor, said the printing trade to the inventor, little thinking that the challenge would be accepted.



10. LINOTYPE MACHINE

The Linotype. In the year 1886 news came from America that the problem of mechanical type-setting had been solved, and, in 1889, a Linotype machine was brought over to this country and set to work. Though not the perfected machine now operating in newspaper and book offices all over the country this early specimen demonstrated that the main problems had been solved, and that the mechanical compositor was an accomplished fact.

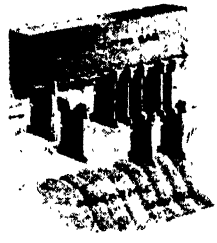
Like nearly every mechanical invention of importance, the Linotype composing machine [10] is a growth, a combination, and an adaptation of devices previously existing. At the front of the machine is a keyboard, borrowed from the piano-keys, applied early by type-setting inventors and brought into practical use by the typewriter, and at the side you see what is actually a type-founding machine, while in the middle are the matrices and matrix channels variously developed [14]. The makers of the Linotype thus describe its evolution: "First in order were matrix machines, designed to punch letters one after another in lead or papier-maché, and thus produce a page or column matrix, from which to cast a stereotype at a subsequent operation. Next came machines in which a number of dies were composed in a line, the line justified, and the entire line then impressed at one operation in some matrix material. During the development of the matrix machine the revolutionary step was taken of casting from the machine-made matrices independent type lines, or slugs, now known the world over as 'Linotype.' Last, the typewriter keyboard was applied, and the machine completed."



11. LINOTYPE MATRIX
a. Letter-die *b.* Grooves

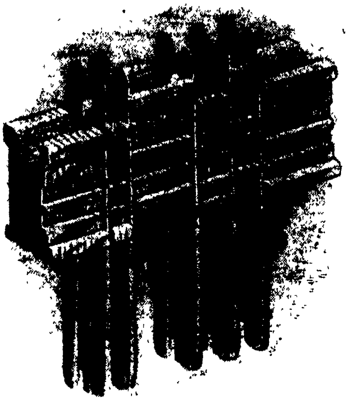
What the Machine does. The mind of the hand compositor is occupied with reading the copy, selecting the letters, placing them in the setting-stick, spacing out lines, and justifying. Now let us see what this intelligent machine does. The Linotype is not yet able to read copy or spell words; but it selects the matrices, places them in line, spaces out, and justifies correctly.

Complex as the Linotype machine is, it is not difficult to understand, because every part acts directly. The *keyboard*, D [14], has 90 type keys and a space key, J. The operator has set his copy in the holder, and taken a phrase into his mind. He taps letter after letter on the keyboard till a word is spelt out, then touches the space key, and on to the letters again. At every click of the keys there is the clink and slide of brass, and yellow metal flashes along the endless belt, F, running at a slant above the keyboard. The belt extends under a series of vertical channels, E, short at the right, and lengthening to the left, and above rests a broad, flat box, almost triangular in shape. This is the matrix magazine, A. Within the box lie long grooves containing winged plates of brass;



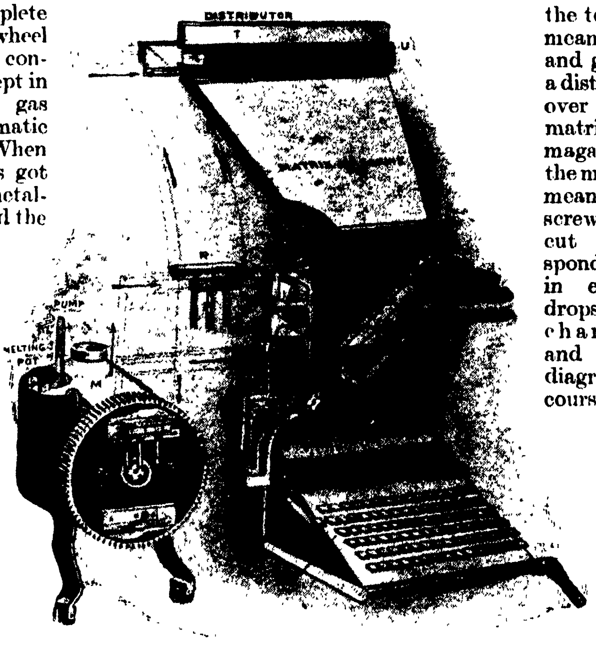
12. DISTRIBUTION OF MATRICES

these are the matrices. In the vertical edge of the little plate a die of a letter is deeply cut [11*a*]; the triangular cut in the head is grooved [11*b*], and the proportions of the grooves in every matrix are different. The motion of the key rods, C, releases B, the check escapement of the matrices, letting the proper matrix drop down the channel below, and on to the flying belt, which bears it to the assembling block, G, at the side. The space wedges, I, come from a box, H, through a channel of their own, but in obedience to a similar call, and slip between the words.



13. LINE OF MATRICES
Showing method of spacing

The Moulding of the Type. Though scarcely full, the line will not hold another word or syllable. But the operator does not pause to justify; he merely presses down a handle on the right of the keyboard, and begins another line, and the neglected line moves on to the face of the mould-wheel, K, where the wedge-like spaces are driven up to fill out the line [13]. The mould-wheel carries a mould in which a slot is cut, the exact breadth and depth of the type, and on to this the matrices clamp, forming a complete mould. Behind the wheel is the metal-pot, M, containing type metal, kept in a liquid state by a gas burner, with an automatic plunger pump. When the mould-wheel has got into position, the metal-pot comes forward and the spring plunger jerks a jet of metal into the mould, casting the line of type. This done, the mould-wheel turns round and sets the line on end, level with the trimming knives. From behind comes a pushing blade that drives out the line into a little galley in front of the machine.



14. DIAGRAMMATIC VIEW OF LINOTYPE MACHINE

While all this has been going on our operator has been setting another line, and before it is complete, the mould-wheel is waiting to begin another round. The older engineers could not trust their contrivances to do more than purely mechanical work under constant supervision, but here one act brings on another, and even impetus is taken advantage of with cunning skill. Take, for example, that slanted belt and the matrix channels lengthening from right to left. The assembling block is at the left side, and if not otherwise guarded against, the matrices on the right side of the machine would have to travel more than double the distance of those on the left. Note, however, that the channels on the left are nearly as long as the breadth of the magazine, while those at the right side are shorter. The comparative brevity of the channel, and the speed of the flying carrier belt, enables the most distant matrix to arrive at the assembling block in the same time as the nearest. Say capital X is at the far side, and small "e" is just above the assembling block. X has to drop down its short channel and fly along the belt, while "e" has only to drop down its long channel; but no matter how quickly you strike "e" after X, the X will get there first.

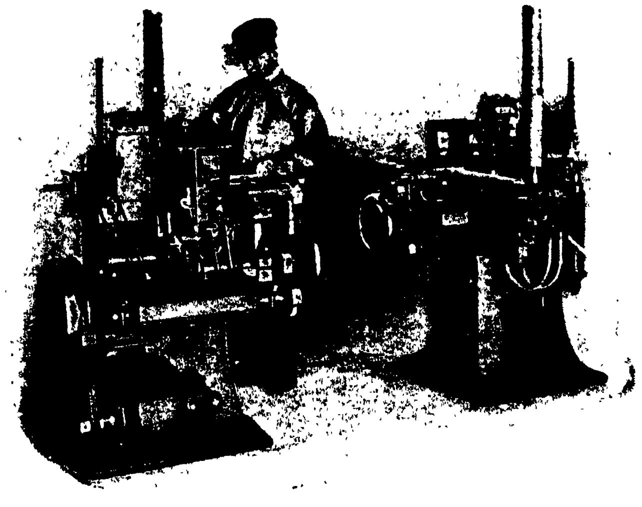
Distributing by Machinery. When a line is *cast*, the matrices must be distributed, or cleared out of the way, and here again the automaton acts without direction. The used matrices are lifted up to the top of the machine by means of an elevator, R, and given into the grip of a distributing bar, T, fixed over the mouths of the matrix channels [12] of the magazine. Along this bar the matrices are moved by means of three endless screws, and, the bar being cut into wards corresponding to the grooves in each matrix, each drops into its proper channel. The arrows and dotted lines in the diagram indicate the course followed by the matrices.

To get the most out of a machine so finely adjusted, the operator should not merely learn his keyboard, but should make himself acquainted with all its parts, so as to feel the least hitch and remedy it at once. He must also keep in mind that even the smallest correction involves the resetting of a line, and an "out" may call for setting a whole paragraph over again. The machine has great advantages and small disadvantages, and the latter can be minimised by careful workmanship. An average Linotype operator is able to produce as much as five hand compositors, but an expert will easily double that speed. The illustrations 10-14 have been supplied by the Linotype and Machinery, Ltd.

The Monotype. The Monotype is another triumphant combination of modern mechanical ideas. The typewriter, the pneumatic tube, the telegraphic ribbon, the cone drum, the Jacquard weaving apparatus, and several other new ideas have been utilised by the inventor of the Monotype. Properly speaking, it is not one, but two machines, the one with the keyboard producing the record [15], and the other casting the type [16]. The keyboard is of vast extent, having no fewer than 257 keys, thirty being space regulators, 225 for letters, spaces, and signs, and the other two for justifying scale and reversing actions. At the back of the board is a ribbon of paper, rolling off one spool on to another, and, unseen below, rest 31 punches. A pneumatic pump drives air into the keybank at a pressure of 15 lb. to the square inch. These are the tools of our machine, and now see how they work.

15. MONOTYPE COMPOSING MACHINE

Punching the Ribbon. When a key is depressed, it releases the current of air, which drives one or two punches into the ribbon, as the case may be. Every key releases a different pneumatic combination of punches, making different patterns on the ribbon, translating the copy into a perforated record, similar to the telegraphic tape or the phonographic cylinder. The spacing and justifying arrangement is ingenious. When the line is set, or rather punched, to within four ems of the end, a bell rings, and as the operator puts in the last letter he can get into the line, he touches a green key that indicates two numbers on the justifying scale drum. Obediently he presses these, and the intelligent machine, having previously kept count of the number of spaces in the line, proceeds to make a record on the paper which will give exactly the proper addition in thickness to each space.



Back view

Front view

16. MONOTYPE CASTING MACHINE

Casting and Moulding. The spool with the ribbon record is now taken to the casting machine, which looks very complex, but is in reality simplicity itself, the machine really being three put in one. First, there is the casting machine proper, with its pot of molten metal and forcing-pump and valve, set below the mould holder. Secondly, the die case ready to direct the matrices on to the mould as required. And thirdly, pneumatic apparatus that directs the setting of the die on the mould, under the direction of the perforated paper or ribbon record. Now we can follow the whole action. The perforated tape moves forward one marginal perforation under the air-pressure bar, releasing the air to propel the mechanism of the die-case, and placing the matrix [17] required into its proper position to the mould; the matrix-case [18] adjusts itself to the mould, to the top of which the matrix is clamped; the force-pump injects the molten metal and the type is cast; the matrix-case lifts itself from the mould, and the carrier bears the type into a channel, where the line builds itself up. At the end of the line the casting operation and type-pusher stops and the galley gate lifts to permit of the line being automatically pushed into its place on the galley.

Whilst one type is being delivered into the channel another is being cast in the mould, hence the rapidity of the whole operation.

So long as type-metal and perforated paper are supplied to the machine the production and composition of type continues unchecked. The illustrations 15-18 have been supplied by the Lanston Monotype Corporation, Ltd.

On the relative merits of these two thought-saving machines it is not our province to give an opinion. The Linotype is probably the handier and better suited for newspaper work: the Monotype is the more mobile, and presents a larger range of letters at one time. Movable type has its advantages, but the solid line is more easily handled. Looking at them both, the wonder in our minds takes the form of the inquiry, What next? The transition from the monotype record to the phonographic record is very small. Will any genius make the bridge, and change spoken words into solid type?

17. MONOTYPE MATRIX (Much enlarged)

A Look Round the Composing-room. It must not be understood that a composing-room is only a place for setting type, and wholly furnished with composing frames. Set at places convenient for the business, stand tall frames called racks, holding as many as thirty-five cases in them. These cases are filled with various kinds and sizes of type, some holding large sizes, some small type rarely used, and others fancy types of all sorts and sizes. We have mentioned the leads, the slips of metal which the hand compositor uses to make space between the lines of type; there is a rack containing nothing but cases of leads, ranged between slips of wood in sizes from four-ems up to sixty. When the compositor needs leads, he goes to this rack, draws out the case containing the size he wants, and lifts out a handful.

The Brass Rules. In many offices, there is another set of cases most important to the compositor. These are what they call the *brass-rule cases.* Here, in neat boxes, exactly fitted to the varying and graded lengths of the rules, lie the slips of brass that print the column lines, cross-lines and other sorts of lines, needed in tables, or matter that requires marks of separation between one part and another. One case holds the thin brasses—eight-to-pica, as they are named—and on the side the length of each is engraved, usually running from two-em up to 40. The next case holds thicker brass rules, six-to-pica. Another is full of what are called fancy brasses, thick and thin, long and short, waved, starred, double, triple, and variously designed, for ornament. Then, in all newspaper and most other offices, there are what they call column rules, generally two-to-pica, but graduated to a thin line on the face. To produce the heavy black lines in obituary notices the column rules are just turned bottoms upward.

The Furniture. Borders, fancy dashes, and other ornaments belong to the jobbing department, and we shall see them when that department is entered. But there are many things yet to be seen in the composing-room, necessary to all printers. The spaces between pages, blank pages in books, and large breaks in between one piece of type and another, are all filled in with what is called *furniture.* Furniture is made of wood and metal. Look at a case of metal furniture first. It is made up to pica both in length and thickness, and begins at four-em broad by one-em thick. Next are the two-em thick, and these seem like two pieces cast together; the three-em have holes in the middle, and the four-em are made hollow squares. This principle is followed in all sizes of metal furniture, for obvious reasons of economy and to render the weight of metal as light as possible. Excepting the smaller sizes, every breadth of furniture runs up to eight-ems thick, and a solid bar of lead 15 in. long by about 2 in. thick would be rather difficult to handle. Wood furniture is made of seasoned oak and supplied in lengths which the printer can cut up to suit himself, the thickness being graded in the same way as the metal furniture. Metal furniture is more liable to break in use, but is more rigid, and better suited for small spaces.

Galley and Forme Racks. Round the room there are numerous other racks and stands. This tall, narrow frame is a *galley rack,* and into it are slipped the galleys full of type awaiting making up into pages, author's corrections, or sometimes a dilatory compositor's correcting. Beside it stands the *galley press,* an iron stand like a long, narrow table, railed on both sides with a heavy iron roller covered with felt resting on the rails. The galley to be proofed is laid on the table, rolled with ink, covered with a slip of paper, and run over with the heavy roller, the result being a slip galley proof.

18. MONOTYPE MATRIX MOULD

Then there are *forme racks,* holding in vertical position sets of pages of type locked firmly in iron frames technically called *chases;* racks for keeping in good order the iron chase frames themselves; long tables covered with type, some of it tied up for keeping, some of it awaiting distribution; and, most conspicuous of all, the large, heavy tables, iron-topped, called *imposing stones,* the uses of which we describe at length on a later page.

Continued

A SHORT DICTIONARY OF TERMS USED IN PRINTING

ACCENTS—Accented letters.
Ads.—Advertisements.
Apron—Flap of paper pasted on matrix.
Ascending Letters Letters with heads extending above body, as b, d, f, h.

BACK MARGIN—Inner edge of page.
Bank—Bench for sheets of hand press.
Bastard Fount—Type with body out of proportion to face.
Bastard Title—Abbreviated title-page.
Beard—Space on body of type allowed for ascending and descending letters; also called shoulders.
Bearer — Type-high metal, used to modify impression.
Bed—Type-carriage.
Bevel—Sloped edge of stereotype plate.
Bill—A poster.
Bind—Obstruction of type in locking-up.
Blanket—Impression pad of wool, felt, or rubber.
Blocks—Mounted plates, or woodcuts.
Board—Flat piece of wood for holding type.
Bodkin—An awl used in correcting.
Body—Shank of a letter; page without headlines, folios, or footnotes; book, without preface, title-page, &c.
Bourgeois—Size of type 9 points).
Boxes—Divisions of type-case.
Brace—Sign of inclusion, coupling.
Brass Rules—Slips of brass used for printing lines.
Break—End of a paragraph.
Brevier—Size of type (8 points).
Brilliant—Size of type (3 points).

CAP.—Capital letter.
Case—Shallow wooden tray divided into compartments for holding loose type.
Cast—Moulded metal, type or plate.
Cast Blackening of sheet at second impression by cylinder or tympan fouled by ink from first printing.
Casting-box—Iron box, forming, with the matrix, the mould of type or stereotype plate.
Cast-off—Calculating length of MS.
Catch-line—Words at head of galley denoting contents.
Chase—Iron frame in which type is locked.
Clicker—Workman who distributes copy and makes up pages or columns.
Clump—Type-high metal, put round pages to be stereotyped.
Coffin—Type-carriage of press or machine.
Copy—Manuscript.
Cuts—Woodcuts, or illustrations.
Cylinder—Horizontal roller on printing machine.

DESCENDING LETTERS—Letters with tails below the body, as g, p, q, y.
Dis.—Type ready for distributing back into case.
Dressing—Placing forme on machine, and preparing cylinder.

ELECTRO—Electrotype plate of page or picture.
Em-quad—Space the square of depth of type body
English—Size of type (14 points).
En-quad—Half of em.

FACE—The letter on the type.
Footstick—Half-wedge put at bottom of type in chase, for lock-up.
Fore-edge—Outer margin of page.
Forme—Type locked in chase; specially applied to groups of pages.
Frame—Wooden or iron structure holding type-cases, forming bench for cases in use.
Friar—A light mark on printed sheet.
Frisket — Paper-covered frame, with opening cut to size of type; folded on the tympan to protect the sheet.
Furniture—Metal or wooden blocks for spacing between pages.
Flong—Substance of stereotype matrix.

GALLEY—Tray for holding type when it is set.
Galley Press—Press for proofing type on galley.
Galley Proof—Slip printed from galley.
Gem—Size of type, (4 points).
Great Primer—Size of type (18 points).
Gripper—Bar set on cylinder to take on sheets.
Gutter—Space between pages in forme.

HAIR SPACE—Thinnest of spaces, eight to the em.
Hand Roller—Ink roller of hand press.
Hoe—A rotary printing machine.
Hot Plate—Steam-heated plate for drying stereo matrix.

IMPOSING STONE—Table on which set type is prepared for printing or stereotyping.
Imposing Schemes—Method of placing pages so that they will print in order.
Impression—Stamp of type on paper.
Impression Cylinder—Cylinder carrying and impressing the sheet on type.
Imprint—Name and address of printer.
Indent—Space shortening first line of paragraph.
Inferiors — Index figures or letters, smaller than type body, ranging with bottom of letters.
Inner Forme—Set of pages containing the second and second last pages of a sheet.
Italic—*Sloping type, like this.*
Inset—Supplementary matter.
Inverted Commas—Quotation marks.

JOB—Any work not a book or pamphlet.
Jobbing—Doing odd work; commercial printing; small jobs.
Justify—Spacing out the line; setting different sizes of type to each other.

KISS—Rollers coming into contact.
Knocking-up—Making sheets lie evenly over each other.

LAY OF CASE—Arrangement of type in case.
Leads—Lead slips used for putting spaces between lines.
Linotype—Type-setting machine, producing solid lines.
Locking-up—Wedging type in chase.
Long Primer—Size of type (10 points).
Lower-case—Small letters of the alphabet; the case used for the small letters.
Lye—A type-cleansing liquid, usually made of potash.

MS.—Author's copy.
Make Even—Finishing copy at end of line
Make-up—Putting type together into pages or size of job.
Making Ready—Preparing tympan or impression cylinder for printing.
Matrix—Mould of type or plate.
Measure—Length of line, expressed in ems of pica.
Minion—Size of type (7 points).
Minnikin—Size of type (3½ points).
Modern—Plain Roman type.
Monk—Black spot on sheet, caused by inkstain or other dirt.
Monotype — Machine which moulds, casts, and composes type in single letters.

N.P.—New paragraph.
Nicks—Marks on front of type shank.
Nonpareil—Size of type (6 points).

O.S.—Old style. Modern imitation of antique type.
Octavo—Sheet folded into eight leaves.
Outer Forme—Forme containing first and last pages of a sheet.
Overlay—Sheet patched to produce good impression.
Over-run—Altering the measure of type to take in corrections, or to go round an illustration.

PACKING—Sheets of paper and blanket in tympan or on cylinder to graduate impression.
Pearl—Size of type (5 points).
Pitch—Adjustment of type to cylinder.
Pica—Size of movable type first used; standard of measurement (12 points).
Pie—Type thrown into disorder.
Planer—Flat block of wood for levelling down type.
Platen—Impression plate of hand press or machine.
Point—One-twelfth of pica.
Points—Steel pins fixed on forme to secure register of pages.
Process Blocks — Illustrations produced by a photographic process.

QUADS—Spaces larger than em.
Quarto—Sheet folded twice, giving four leaves.
Quoin—Wedge for locking type in chase.

RACKS—Holders for cases, chases, and tools.
Reader—A corrector of proofs.
Register—Printing pages of one leaf on the back of each other.
Reglet—Wood slips for spacing bill lines.
Rollers—Ink distributors.
Roman—Common type, not *italic.*
Rotary—Type-cylinder machine.
Rough Proof—Rough impression of type pulled for correction.
Ruby—Size of type (5½ points).

SANSERIF—Form of type without fine strokes at terminations of lines. Like this: **SANSERIF.**
Screw-chase—Chase fitted with screws for locking up instead of wedges and quoins.
Serif—Fine lines at ends of letters.
Setting-stick—Tool into which the compositor sets type.
Setting-rule—Slip of brass against which the compositor sets, shifting it line by line.
Shooter—Wedge for driving quoins.
Sidenotes—Notes on margin of page.
Sidestick — Half-wedge laid on side of page for locking-up.
Signature—Printer's letter to mark number of a sheet—*i.e.*, in a book, &c.
Small cap.—Capitals same depth in face as lower case.
Small Pica—Size of type (11 points).
Slur—Defective impression.
Sorts—Special letters of a fount
Spaces—Type without face for making space between words.
Superiors—Index figures or letters, very small, and cast to range with top of letters.

TAKE—A share of copy.
Thick Space—Space, three to the em.
Thin Space—Space, five to the em.
Tweezers—Small pincers for picking out letters.
Tympan—Parchment-covered frame on hand press that carries the sheet on to type.

UNDERLAY—Sheet or patchings put under type to regulate impression.
Upper-case—Capitals; the case used for capital and small capital letters, figures, etc.

VIBRATOR ROLLERS—Rollers conveying ink from ductor to ink slab.

WAVER ROLLERS — Rollers set diagonally to distribute the ink.
Web Machine—Machine supplied with paper from a reel.
Wrong Fount — Letter of different character from the fount being used—marked w.f. on proof.

THE SHIPS OF THE WORLD

Shipbuilding. The Evolution of the Modern Ship. Early Types of Ships. Sailing and Steam Ships. Wood, Iron, and Steel Ships

By Dr. J. BRUHN

THERE are few professions more interesting and fascinating than that of the shipbuilder. To be familiar with all the various details and conditions affecting the immensely complex floating structure that constitutes a modern ship requires a general knowledge of nearly every natural law, and more or less proficiency in other branches of engineering science. Moreover, its connection with the sea will probably, to most young minds, give this profession additional charm. The builder of ships has existed almost as long as the builder of dwellings; he has held as honourable a position in human society, and added his share to the progress of the world, although his material was not, in the past, so durable as that of his brother builder on land: and his structures have, therefore, and on account of the precarious nature of the sea, not been left for successive generations to admire.

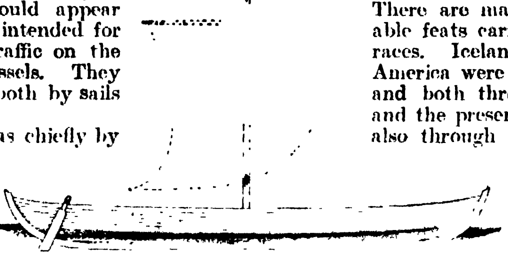
How to Become a Shipbuilder. One who wants to become a shipbuilder ought, in the first instance, to aim at a sound general education. It will form the broad basis for the specialised knowledge required to grasp the principles underlying all the many intricate problems with which a naval architect is called upon to deal, and it will give the breadth of view necessary to ensure progress by the throwing off of the fetters of inherited methods, when such action is desirable. Having acquired, as far as possible, a good general education, the best way to become a naval architect is to begin to serve an apprenticeship in a shipbuilding yard. All the technical teaching at schools and colleges cannot be a substitute for the practical training in a place where actual building operations are being carried on. A general knowledge of ships and the art of building them will be acquired during the apprenticeship prior to beginning theoretical studies, and it is desirable that this should be the case, as it is only while engaged in such real work, that the want of other knowledge makes itself felt, and the want of it is a great lever in acquiring it. It is desirable that the apprentice should get as all-round a training as is possible in the various branches of this many-sided profession, but the chief weight ought to be laid on the operations connected with the manipulation of the main structural material. Having become fairly familiar with practice, the apprentice may profitably begin his theoretical training either by being alternately at the shipyard in the summer and at college during the winter, or by being engaged at the works during the day and studying at night. In thus alternating the instruction, the two sides will naturally complement each other, and a one-sided training will be avoided. With regard to the selection of technical subjects to be studied, it will be well not to confine it too narrowly to those more directly connected with shipbuilding. Mathematics ought to be given a leading position. This subject is, unfortunately, often looked upon as something of no practical value. This view originates in the failure to appreciate its nature and its bearing upon practical questions. Mathematics is, in reality, merely the instrument of all rational comparisons and estimates when they are of so complex a nature that none but a genius could carry them out by a direct inspection. As an instrument, mathematics requires careful handling and a mind to guide it. It cannot be worked mechanically with success. Statics, dynamics, kinematics and all the other branches of applied physical science are built up entirely upon mathematics. The knowledge of this subject is, however, valuable not only on account of its direct application, but it trains the mind generally to work logically or rationally. In addition to applied mechanics it will be well for the student to fortify himself as far as possible with a general knowledge of the other branches of engineering, such as civil, mechanical and electrical engineering.

The Evolution of Shipbuilding. The practice of the art of shipbuilding represents the sum of the knowledge of the past on that particular subject, and it is indispensable to be familiar with it But, in addition, a knowledge of how it was arrived at by successive modifications in previous practice is also of great value to the naval architect, as it will enable him better to formulate reasonable opinions as to how the practice will develop in the future, while he himself will be connected with it.

In a course of instruction like the present it is, therefore, desirable to begin with a historic outline of the art of shipbuilding, showing broadly how it arrived at its present-day conditions. Following this a description will be given of modern steam and sailing vessels, to give a prospective naval architect a general idea of existing ships before he seeks to know how to build new ones.

From the earliest times ships have played an important part in the progress of the world. In them the sparks of civilisation were carried from established centres to other lands, as they carried with them a sacred fire kindled at the home temple. They have then spun the threads of attachment between mother and daughter civilisation until the latter grew up to become independent. This function of the ship as the tie between nations has been well described by John Ruskin, when he says: "The nails that fasten together the planks of the boat's bow are the rivets of the fellowship of the world."

The Cradle of Shipbuilding. It is probable that the early civilisation of the plains of the Euphrates and the Tigris created some measure of shipping on the rivers and in the Persian Gulf; but it was not until the development reached the eastern shores of the Mediterranean that the production of sea-going ships became common. Here stood, therefore, the cradle of the ancient shipbuilding which should develop into the modern industry. The Phœnicians, who inhabited the strip of sea border nearest to the Babylonians and Assyrians, naturally became the first to build ships and make extensive voyages in them across the seas, where they founded colonies and created cities at the most distant parts of the Mediterranean. It was only through their shipping that the Phœnicians became such a powerful nation, the traces of which remain to this day. In addition to their country's favourable position they possessed an abundant supply of excellent shipbuilding material in the forests of Lebanon. What their ships were exactly like we cannot say, but from the fact that they made long voyages we can conclude that they must have been of a fair size and reasonably strongly built. The Egyptians, with their high civilisation, found it necessary to employ ships even for extensive voyages, although most of their shipping was no doubt carried on on the Nile. More information exists with regard to the Egyptians' ships than those of the Phœnicians, as the former were in the habit of recording much interesting information in the highly durable material of the Libyan stone. The pictorial representations of ships that have been preserved in this way are, however, not to be relied upon for exact information as to size and proportions. These ships would appear to be more sailing barges, intended for carrying on the heavy traffic on the river, than sea-going vessels. They were, as a rule, propelled both by sails and oars.

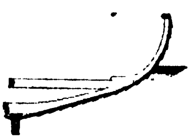


1. VIKING SHIP

Greek Ships. It was chiefly by the ships of the Phœnicians that the earlier civilisation was carried across the Mediterranean to Greece. The Greeks did not, however, improve much upon the ships of the Phœnicians, although their shipping developed considerably from the necessity of keeping in contact with all the many colonies they founded on the coast of Asia Minor and Africa. The ships of the Greeks have often been found pictorially represented upon the vases of that day which have been unearthed in recent times. But, as in the case of the Egyptian ones, these representations cannot be relied upon for exact information regarding size and proportions, as they consisted of more or less conventional outlines intended more for decorative purposes than for correct information with regard to the ships. It would appear that these vessels must have been small—at any rate, compared with more modern ones. Usually they were practically open or without a deck to protect the crew and cargo from the weather. They were probably propelled by sails only when the wind was right aft, as the art of utilising a beam wind to the greatest advantage was not discovered until later. The land was rarely left out of sight on the voyages, a course being followed from promontory to promontory. From Greece, civilisation was again carried westwards, this time to Italy, by means of ships, and the Roman republic, later on the Roman Empire, became the centre of the world's maritime as well as other interests. Like the Greeks, the Romans carried on extensive intercourse with their colonies in Africa and Spain. For a long time a keen rivalry was carried on with Carthage, which owed its foundation to the earlier activities of the Phœnicians, but eventually the Carthaginians were subdued.

Roman Ships. The ships of the Romans were to a greater extent imposed by immense activities in other directions than objects constructed for the love of maritime pursuits. Their character remained very much the same as that of the Greek ships. They were more like land structures made to float than shipshape creations. Above the water they were of a fantastic construction, with erections for fighting-men, protective hoods for officers, etc. At the waterline they had rams for damaging the vessels of the enemy, and rows of long oars gave them the appearance of huge multipedes. The Roman colonies in Spain and in the South of France became after a time more directly interested in shipping than the mother country. The inhabitants of the west coast of France were particular adepts in the art of shipbuilding, according to the very circumstantial reports written by Julius Cæsar while extending the power of Rome in these regions.

The Ships of the Vikings. About the time of the fall of the Roman Empire an independent development in shipbuilding took place elsewhere. The people who inhabited Northern Europe had by this time also developed a considerable amount of civilisation, and in the art of shipbuilding they had attained a high degree of perfection. There are many records of the remarkable feats carried out by these northern races. Iceland, Greenland, and North America were reached towards the west, and both through the English Channel and the present Straits of Gibraltar, and also through the rivers of Russia, the Mediterranean and Black Sea were reached.



2. VIKING SHIP, CROSS SECTION

Less is known of the buildings erected on land by these people than of those in the south, as they were of wood, easily subject to decay and fire. On the other hand, more is known about the ships in the north, as it was there a frequent custom to bury, with a dead chief, in huge mounds of earth, his ship and other things belonging to him. In recent times two vessels have thus been found, and others have been discovered in wood-preserving peat bogs. In this way, very reliable information is obtained with regard to the ships of Northern Europe at that date. One of these viking ships, as they are called, was discovered in Norway in 1880. It is represented by 1 and 2, which show a side view and a cross section respectively of the restored vessel. She was 78 ft. long, 16 ft. 7 in. broad, and 5 ft. 9 in. deep. The keel was the main timber, being 14 in. deep and 4½ to 7 in. thick. The vessel is what is called *clinker built*—that is, the outside planks overlap each other, as shown by 2, and as is usual now in the case of rowing boats and other lightly-built crafts. The planks are only 1 in. thick, and are clinched together with iron nails. They are, however, not clinched to the frame timbers in the now usual way, but are tied to them by means of tough roots. The necessary holes in the planks for this purpose are made in thick protuberances, left on the inside when the wood was prepared. By this ingenious method the builders avoided the necessity of having holes in the outside planks, at the back of the frame ribs, where a leak would be liable to occur, and where it could not be readily got at and stopped. The foundation for the mast, which was a heavy concentrated weight to be carried in a craft of so light construction, was of a design that has hardly, if at all, been improved upon in the most modern yacht construction, where the same problem of distributing a concentrated weight over a very light structure has to be dealt with.

Early Efficiency in Construction. These early shipbuilders were also well aware of the principle that where a minimum of material is to be sufficient, there must be a high degree of excellence of workmanship. It may be doubtful whether vessels have at any time been built which, taken all in all, were more efficient for the intended purpose than these viking ships of a thousand years ago. They possessed the highest degree of strength with the minimum of material. Lightness was of the greatest importance in these vessels from the fact that they had often to be hauled up on land. So easily were they handled that it is even recorded that on occasions when something could be gained thereby, they were transported on rollers for considerable distances on land. They had to be propelled by oars, to be able to run up rivers and creeks, and at the same time they could utilise the wind when it was well aft. The general form adopted to give sufficient stability and a minimum of resistance to propulsion under these conditions is such that it would be practically impossible to improve upon it now, in spite of all the development of modern science.

The deep keel is designed in the most efficient way to protect the vessel when taking the ground, which was necessary when landing was effected in those days of no harbours. The rudder is hung on the starboard, or right side, of the vessel, and could easily be unshipped, and would in any case, with the arrangement adopted, take no damage if touching the ground. It is practically the same arrangement as that adopted in many lifeboats of the present day, designed with a view to the difficulties encountered in landing on an unsheltered shore. In these swift and handy vessels the Vikings swept down upon the remainder of Europe, and the influence of the North was being carried to the eastern shores of Great Britain at the time the Romans were still keeping up communications with the southern ones. The intermingling of the ideas of the classical nations with those of the North may not have been without influence on the development of the maritime affairs of the country which was to become, in modern times, the centre of the world's shipbuilding industry.

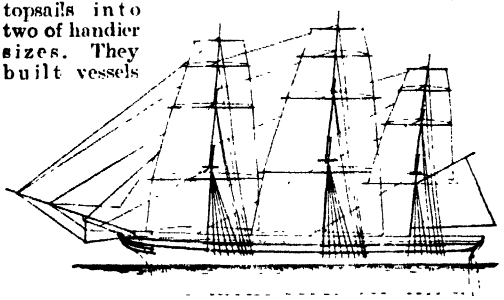
Ships of the Middle Ages. During the early part of the Middle Ages, shipping interests were still chiefly centred in the Mediterranean. It was more particularly the Italian republics that developed the maritime pursuits. The Venetians possessed an extensive fleet of merchant vessels, and kept up a brisk trade with the East. Their ships were, however, more fantastic and picturesque than highly efficient, and no very radical improvements were introduced. The Genoese were, later on, the keen rivals of the Venetians. In Northern Europe the Hanseatic League took the lead in maritime affairs. There was, however, right through the Middle Ages, very little development in the art of shipbuilding. The old ideas were perpetuated, and ships remained very much of the same character as before. With their fantastic trappings, and with their often irrational designs, they were not nearly so efficient for their purpose as the earlier ships of the vikings.

The Genoese were the first to use more scientific methods of navigation, and more rational methods in handling their ships. They are usually credited with discovering the way to utilise a beam, or side wind, to the greatest advantage. With that discovery the use of oars as a means of propelling seagoing vessels ceased to be a necessity, and the time became ripe for the extensive navigation of the high seas. It was at this time that Columbus, after leaving Genoa, prevailed upon the King of Spain to fit out the expedition that led to the discovery of America. This was, however, only one of a long series of discoveries made by Spanish and Portuguese sailors, and, as a consequence, the centre of shipping interest moved again westwards. When Spain and Portugual declined, the Low Countries took the lead, and finally it passed to England. At this time, improvements in ship construction were still very slow. The general character of the ships remained unchanged, although the increased experience caused modifications in details.

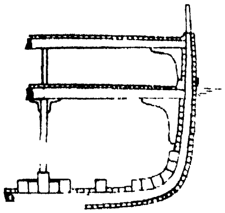
Developments in the Nineteenth Century. The very earliest ships were propelled entirely by oars, and for ages this method of propulsion was retained as a stand-by when there was no wind. Eventually, with the increased knowledge of how to manage the sails, the use of oars was discarded for seagoing vessels. By the beginning of the nineteenth century the steam engine had been invented, and put to use for various purposes on land. It was not long before it was realised that there was here a power which might, with advantage, take the place of the sails and the uncertain wind as a means of propelling ships. The idea of providing a vessel with the power to move it by other than human labour occurred even to the Romans, who, it is reported, had some vessels propelled by paddle wheels worked by oxen. It was not, however, until physical science, in the eighteenth century, had developed sufficiently to make a reasonably efficient steam engine possible that the employment of mechanical power for the propulsion of ships became common. For a long time after the introduction of steam power into ships sails continued to be used in the majority of vessels, and even in those where steam engines were fitted, sails were extensively carried in those days as a stand-by in the event of the coal giving out or the engines failing. The outline of the history of the sailing ships may therefore be continued up to the present day, before the evolution of the steamship is sketched.

East and West Indiamen. In the early part of the nineteenth century a rivalry sprang up between England and the United States of America in the matter of shipping similar to that which had existed between Greece and Rome and their respective colonies. The English merchant vessels were up to this time built entirely on the old, established lines. They were of bluff forms at the ends and consequently of slow speed. On the other hand the underwater part amidships was of a rounded form which did not admit of a large amount of cargo being carried in a vessel of given dimensions in spite of the fulness of the extremities. In the rig and general arrangement these vessels still retained some of the old fantastic features, then thought to be indispensable in a ship. This type of sailing vessel was best represented by the so-called "East Indiamen," owned by the old East India Company, and trading to the East. They carried a relatively small cargo, and a large crew, and could be utilised as ships of war if required. Later on another type developed—namely, the so-called West Indiamen—which were somewhat more efficient from a commercial point of view as they carried a larger amount of cargo, and had a much smaller crew.

American Influence on Sailing Ship Construction. In the creation of a more efficient type of sailing ship the Americans came to contribute considerably. They had the great advantage over the inhabitants of the mother country of being a young nation unfettered by previous conventional ideas with regard to the construction of ships. In addition to this advantage the Americans were favoured by abundant supplies of wood conveniently at hand. It was therefore natural that they should take the lead. In the first instance they improved the speed of ships by making the form of the vessel sharper towards the extremities, while they at the same time increased the cargo-carrying capacity by making the form amidships straighter in the side of the vessel and fuller under water. In other words, they utilised the space better than had been done before, and made a vessel of given dimensions more efficient all round. The Americans also introduced labour-saving appliances in the handling of the sails. They were thus the first to divide the large square topsails into two of handier sizes. They built vessels of larger tonnage, and relatively longer, than had been done before, and as the sails which these ships would have required, if provided with only the usual three masts, would have been too large, they introduced an additional one. Figures **3** and **4** show a typical example of American wood sailing ships of the period just prior to the introduction of the double topsails. Before the introduction of railways across the continent an extensive trade was carried on by these sailing ships between the Eastern States and California, and some famous passages were made on this extensive course right round Cape Horn.

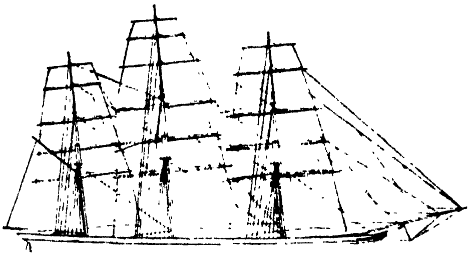


3. EARLY AMERICAN WOOD SHIP



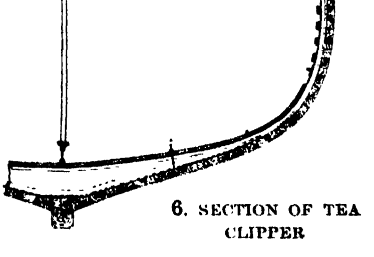
4. SECTION OF EARLY AMERICAN WOOD SHIP

Tea Clippers. The English and Scotch shipbuilders were not slow to adopt these improvements in their new vessels, and in the race from China with tea for the London market the English shipowners were soon able to beat the Americans. These so-called *China clippers* were the fastest merchant sailing vessels built. As the ships of the Vikings came to mark the final development in the combined sailing and rowing seagoing craft, so the China tea clippers may be considered as the highest development of the pure sailing-ship type. They carried on the last struggle of sails against steam in the quick transit across the ocean. After that date sailing ships continued to be built, and they are still being built, but only for trades where cheapness of transit is of greater importance than speed. From this point of view of sailing efficiency, there has been little improvement, if any, since the tea clippers were built. The modifications that have taken place have been in the direction of the economical working and building of the ships all round and in the direction of carrying a larger amount of cargo in a vessel of a given length, breadth, and depth. Figures **5** and **6** represent one of the most famous tea clippers. It will be noted that the spread of canvas is very large in proportion to the size of the vessel. The form of the midship cross section [**6**] shows by its fineness that they could not carry a large amount of cargo, particularly as the form was also very sharp towards the ends of the vessel. They were of the so-called *composite* construction, where the frames, beams, and general internal structure are of iron and only the outside planking and decks of wood. This arrangement was adopted in view of the difficulty of obtaining the necessary strength by a purely wood construction in vessels of such fine form and lofty rig.



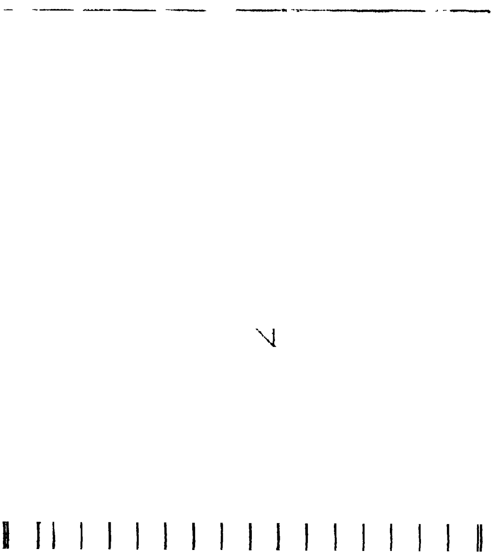
5. TEA CLIPPER

Warships. While the merchant sailing ships developed, so also did warships, but to a much smaller extent. Owing to the large crew that these ships always carried there was not the same inducement to reach a higher degree of efficiency in the arrangement and handling of the sails and in the general working of the vessel. The weight of the structure was also not of the importance it is now in a warship. On the other hand, height of platform for handling the guns was essential, and also



6. SECTION OF TEA CLIPPER

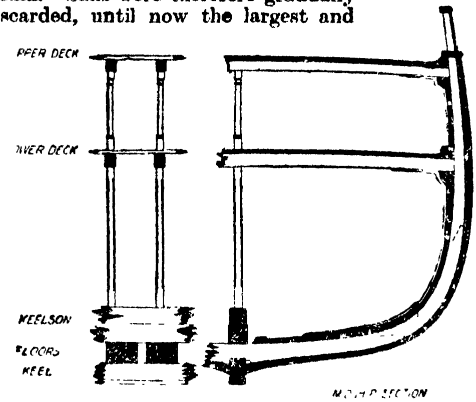
handiness in manœuvring. The consequence was that the wooden sailing men-of-war retained to the last their short, towering, bluff form that can yet be seen at the mouth of most English rivers, where these vessels are now commonly used as training ships for boys. It was such a beautiful ship of the line that inspired John Ruskin, when he wrote of man's capabilities as a gregarious being: "Into that he has put as much of his human patience, common-sense, forethought, experimental philosophy, self-control, habits of order and obedience, thoroughly wrought handwork, defiance of brute elements, careless courage, careful patriotism, and calm expectation of the judgment of God, as can well be put into a space of 300 ft. long by 80 ft. broad."



Steam Propulsion. It was not until the steam engine had reached a certain amount of efficiency that its introduction into ships as the propelling power could become profitable. That point may be said to have been reached by James Watt's invention of the double acting engine. The idea of utilising the power of steam for ship propulsion originated in several minds, probably more or less independently, but Symington may be said to have first realised it in the Charlotte Dundas, a small steam vessel which made its trial trips on the Forth and Clyde Canal in Scotland, in 1802. It was appropriate that the River Clyde should thus see the birth of the first mechanically successful steamer, as this river should afterwards become the world's centre for the production of steamships. It was not, however, until the year 1807 that Robert Fulton, in America, succeeded, by the vessel Clermont, in producing a commercially successful steamer, which could ensure and did ensure the continuous development of steam power as applied to ship propulsion. The beginning of commercial steam navigation took place, therefore, on the other side of the Atlantic; but it was not long before steamers were extensively adopted by British shipowners, and it was by the growth of its steam tonnage that the British mercantile navy should reach the enormous development during last century whereby it outdistanced by far the fleets of all other nations. To begin with, the dimensions of steamers were small. Those of the Clermont were: length, 130 ft., and breadth 16½ ft. Only vessels for rivers and sheltered waters were fitted with the new power of propulsion.

Paddle and Screw Steamers. After a time had elapsed steam was, however, also applied to ocean-going vessels. So far the only method of applying the power had been by means of paddle wheels on the sides of the vessel, and although these proved themselves very satisfactory for river steamers, they were not so for ocean-going ships, where the large wheels were exposed to the blows from the seas and where the rolling might often alternately dip the wheel on one side too deep in the water, or lift it entirely out of the water, in both of which cases the propelling power would be largely lost. In 1839, the screw propeller had been invented by Mr. Smith, and was applied to the Archimedes, a vessel of fair size. This was a great improvement in the method of propulsion as applied to ocean-going steamers, because the screw could be placed low down in the water, where its action was less liable to be interfered with by the movements of the ship or the waves. Although paddle steamers were at that time crossing the Atlantic, they soon died out for that purpose, and the screw propeller has been victorious down to the present moment. Since its introduction the developments have been gradual, and have been principally in the direction of improved engines and boilers. The greater efficiency of the propelling machinery was obtained chiefly by a continuous increase in the pressure of the steam in the boilers and by its more economic use in the engines, first by passing from the simple double-acting arrangement to compound engines, then to triple expansion, and, finally, to quadruple expansion. The principle of the multiple expansion of the steam as it passes from the maximum pressure in the boiler to the minimum in the condenser is simply to get a more gradual, and therefore more economical, supply of work from the steam. This question will, however, be dealt with under Prime Movers. The very latest method of applying the power of steam to ship propulsion is by means of turbines, where reciprocating machinery is entirely done away with, and the steam is made to act directly on a rotary fixed to the propeller shaft much in the same way as water acts on a horizontal turbine wheel, or the wind on the sails of a windmill. By this method the propelling agent remains the screw, but it is usually found advantageous to employ a greater number of them than before—usually two, three, or four are fitted.

Discarding Sails. The first ships for ocean-going purposes to be fitted with steam retained their full complement of sail, in order to save coal when the wind was favourable and to have a stand-by should the engines break down. By the development of more economic, particularly more coal-saving, machinery, and by its being perfected so as to be more reliable, the use of sails became of less importance. In many instances where the speed was high the tall masts, yards, and rigging added materially to the resistance, and reduced, therefore, the speed when under steam. Sails were therefore gradually discarded, until now the largest and most important steamers have only masts for the purpose of carrying signal flags and lanterns, or for supporting cargo derricks. The introduction of the twin screw, with its two independent sets of engines, gave increased safety, and aided in bringing about the above-mentioned result. The consequence is that not only are sailing ships disappearing rapidly, but sails for other than steadying purposes are also vanishing, or have vanished, from steamships.

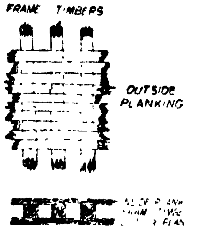


7. USUAL CONSTRUCTION OF WOOD SHIP

The Disappearance of Sailing Ships. The extent to which sailing ships are still being built is shown graphically by the upper diagram on the preceding page. The bottom curve gives the percentage of sailing ship tonnage built throughout the world in each year, the top curve the corresponding percentage of steam tonnage, the horizontal divisions representing years and the vertical divisions 10 per cent. It will be seen that the growth in the production of steam tonnage has been enormous, particularly in the years just before 1889. The increase in the percentage has, however, not been steady, as is seen by the fall in the years from 1889 to 1892. During recent years there has been a tendency for the percentages to be more constant, the steam tonnage remaining at about 90 per cent. and the sailing ship tonnage at about 10 per cent. The second diagram shows the relative yearly waste of steamers and sailing ships. It will be seen from this diagram that the average yearly loss in steamers is about 2 per cent. against about 5 per cent. for sailing vessels.

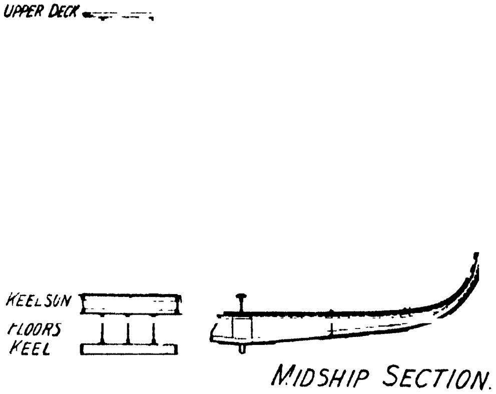
Taking ships on the whole, and ignoring age and material of construction, a steamer may be said to have fully twice the vitality of a sailing vessel. The effect of the yearly building and loss upon the existing tonnage of the merchant fleets of the world is shown in the table in next column, the horizontal divisions representing a year, while the vertical divisions are equal to 1,000,000 tons. It will be seen that in the year 1887 the existing sailing ship and steamship tonnage were equal, but the steam tonnage was in the ascendancy, while the sailing ship tonnage was dwindling. The increase in the steam tonnage has been very steady, and the decline in the sailing ship tonnage has been equally so. In twenty to thirty years from now, sailing ships will be an entirely negligible quantity in the mercantile fleets. The top curve shows the entire tonnage of the world, and it will be observed that it is growing by more than a million tons a year. These curves are derived from the careful statistical records kept by Lloyd's Register of Shipping.

Wood Ships. From the earliest times right up to the beginning of the nineteenth century all ships had been built of wood. This was naturally the material that suggested itself first from its ability to float on the water. For centuries it was supposed that this ability of a material to float was essential to its use in the hull of ships. This idea was, as a matter of fact, wrong, which could be proved by the ability of any tin or light iron kettle to remain floating on the water. In many respects wood was an excellent material for shipbuilding purposes, particularly as long as ships remained of moderate sizes, and under any circumstances it was the only possible material until comparatively recently. Oak and other hard woods were the best for the purpose, but pine was often more conveniently at hand, and cheaper. The general method of construction of wood ships has remained the same as far back as it can be traced. A heavy piece—or pieces—of timber form the keel or backbone of the structure. On it are erected floors and frames, or stiffening ribs. To these the outside planking is attached, as indicated in 7, which represents a midship section of a wood merchant ship. At the top of the frames the beams are fitted across the vessel. In the case illustrated, there are two tiers of beams, one to carry the upper-deck planking, and one to take a deck lower down for the accommodation of passengers or cargo. The frame timbers are planked on the inside to keep the cargo dry. Above the keel, heavy timbers are run along on the top of the floors forming what is called a *keelson*, which is really part of the backbone of the structure, being thoroughly bolted through the floor timbers to the keel. From the keelson, supports are carried up to the deck beams. It is desirable to have as few joints as possible in the structure of a wood ship. It is, however,



impracticable to obtain timber of the form and size necessary to dispense with all joints, and in some instances, as in the case of the frames, it is necessary to have each set of timbers built up of a number of comparatively small pieces, which must then be bolted together. This question of the joining of the individual parts is one of the most difficult ones in wood ship construction, as will be evident from the large wrought iron knees shown in 7, attaching the beams to the sides of the vessel. A very large amount of iron has in this way to be worked into the structure, whereby it becomes so heavy that it would not float if pierced, in spite of the general material being wood. Gradually more and more iron was in this way being used in ships.

Iron Ships. About the same time as steam power was beginning to become general for the propulsion of ships, another epoch-making change was being prepared. Barges were being built of iron plates on the principle of the steam boilers. As they were found to answer satisfactorily, it was proposed to adopt this principle for sea-going ships. For a long time the prejudice against such an unheard-of proposal was sufficiently strong to keep the suggestion from being carried out in practice. Eventually the general superiority of iron as a material for shipbuilding purposes was recognised, and the enormous development of modern shipping became possible. As Great Britain had taken the lead in the change from sail to steam, so it also became the shipowners and shipbuilders of this country that first realised the immense possibilities of the introduction of the new material. One of the first iron vessels, the Vulcan, was, appropriately enough, built on the Monkland Canal, near Glasgow, in the year 1818. The first iron steamer, the Aaron Manby, was constructed in 1821. From that year up to about 1885 the construction of iron ships increased to such an extent that the new material practically displaced wood.

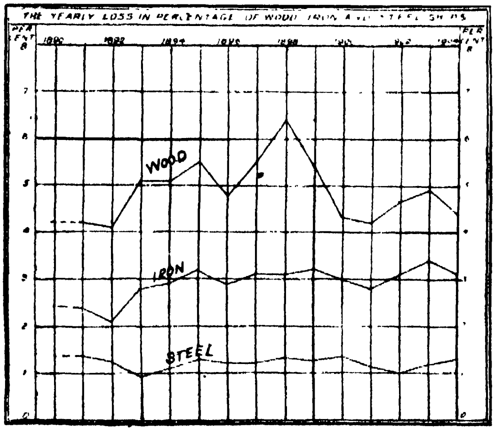


8. CONSTRUCTION OF IRON SHIP

Superiority of Iron Over Wood. The superiority of iron over wood lies not only in the greater strength of the material itself, but also in the fact that the individual parts of an iron structure can be much more effectually attached to each other, whereby the efficiency of the structure as a whole is immensely increased. Moreover, a considerable saving in weight is effected by the use of iron. The specific density of iron is, of course, much greater than that of wood, and, bulk for bulk, iron is therefore heavier. Its strength is, however, more superior to that of wood than its specific weight is greater. A less weight of iron will therefore suffice to produce the same strength as a greater weight of wood. In a general way the structural arrangement of iron ships was the same as that adopted in wooden ships. Figure 8 shows the construction of an iron ship. Comparing it with 7, it will be seen that the keel and keelson still form the backbone of the structure: the floors and frames are fitted as in the wood ship, and the beams and decks are similarly arranged. In lieu of the outside planking, comparatively thin plating is now used. It will, however, be observed that although the general arrangement is similar, the dimensions of the individual parts are reduced very much. For instance, where the outside planking was 4 in. in thickness, the iron plating is only about ½ in., and where the floors were some 12 in. thick, they are now less than half an inch. Iron is so infinitely superior to wood as the material of construction for large sea-going vessels, that the long, shallow, and fast ships now existing may be said to have been an impossibility without the introduction of the new material. A splendid proof of the possibilities of iron was to be furnished not long after its general acceptance as a shipbuilding material, but the vessel in question will be referred to later. In the meantime, it will be desirable to mention the second great change in the material of construction.

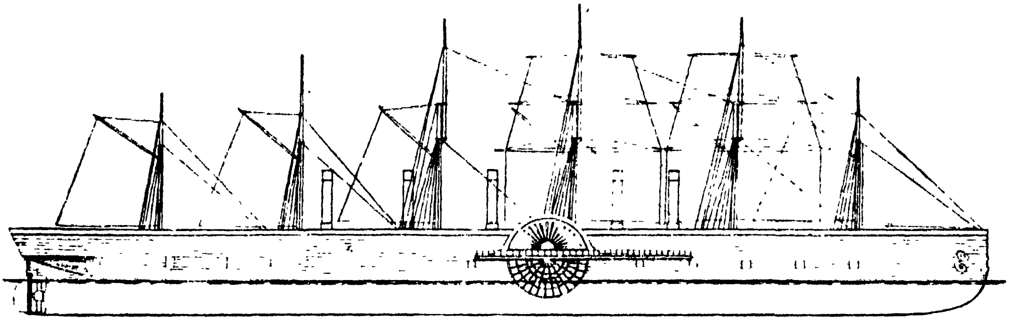
Steel Ships. About the year 1875 an improved method of manufacturing iron plates and angles had been invented. The new product was called *mild steel*. It must not, however, be confounded with the hard material used for tools and similar objects. In reality, the steel used for shipbuilding purposes is more real iron than the commercial product of that name, in so far as its chemical composition is made up of iron [illegible] fewer impurities than the material properly so called. The essential difference between iron and steel for shipbuilding purposes is this, that the latter is stronger, more uniform in quality, and more pliable. It can be given almost any form, to a large extent without the application of heat, which is usually necessary in the working of iron. The introduction of steel was therefore a great improvement, but it did not represent nearly so great an innovation as the substitution of iron for wood; it merely accentuated the advantages of metal over wood. Although both iron and steel are on the whole infinitely superior to wood, they have certain disadvantages. In the first instance, they corrode, particularly so where subjected to the action of the impure water that always gathers in the bottom of ships. A little experience with iron ships proved this, but it was not long before it was realised that a little care and the application of paint and cement practically removed that trouble. Wood ships, particularly those trading in the tropics, were always subject to having the exterior of their bottoms covered with barnacles and other marine growths, which could assume huge proportions and delay the progress of the vessel considerably. It was discovered that by covering the bottom below the water-line by thin copper plates these growths were prevented from attaching themselves to the ship. This expedient was therefore universally adopted in all first-class wood ships. When iron was introduced, the trouble with the growths cropped up again. It was attempted to attach copper plates to the iron bottoms as in the case of wood ships, but with disastrous results, as the two metals set up a galvanic action which consumed the iron. Again experience soon taught that iron ships required a slightly different treatment from wood ones. The more frequent docking and cleaning, and the use of more or less efficient anti-fouling paints, practically removed the difficulty of the barnacle-covered bottom in iron and steel ships.

Number of Vessels of Wood, Iron, and Steel. The effect of the change from wood to iron and from iron to steel in the amount of shipping created each year will be seen at a glance from the diagram above, where the three curves represent the growth or decline of the three materials in percentage of the total amount of tonnage produced each year. It will be observed that iron had already, in 1886, reduced the production of wood ships to about 16 per cent. of the total output of the world, but even this figure has by the combined effect of iron and steel been reduced to only about 4 per cent. in 1904. On the other hand, the immediate effect of the introduction of steel was to make the iron ship disappear even more quickly than the wood one did. Since 1894 iron shipbuilding has been practically extinct, and steel ships have represented 90 per cent. of the total production. The relatively yearly loss of wood, iron, and steel ships is shown graphically in the next diagram. It will be seen that the wastage is, on the whole, fairly constant for each material, but the iron ships are disappearing more than twice as fast as the steel ones and the wood ships more than four times as fast. The net result of the additions and deductions to the existing fleets of the world is shown in the last diagram. It will be seen that there is a very steady increase in the tonnage of steel ships and an equally steady decline in the tonnage of iron and wood ships. Some ten to fifteen years from now the wood sea-going ships will have practically ceased to exist, and in another five to ten years time the iron ship will have gone the same way.



The Great Eastern. The use of iron as building material culminated in the building of the Great Eastern, the most unique specimen of naval architecture that the world had produced. The construction and design of this vessel are well worth careful study even in these days of large steel steamers, and a short reference to them may not be out of place here. It was Mr. Brunel who first conceived the idea of building a ship large enough to steam round the Cape of Good Hope to India without coaling on the way. The Great Eastern was designed and built with a view to realise this idea. Her length over all was 692 ft.; length between perpendiculars, 680 ft.; breadth of hull, 83 ft.; breadth over paddle-boxes, 120 ft.; depth from keel to upper deck, 58 ft. Her tonnage was 22,500 and the displacement 30,000 tons, *at a draught of 30 ft* She was capable of carrying 18,000 tons of coal and cargo, and in addition she had accommodation for 4,000 passengers or 10,000 troops. She was propelled by two sets of engines, one working a four-bladed screw propeller 24 ft. in diameter, the other a set of huge paddle-wheels 58 ft. in diameter. In addition to the two sets of engines she had 195,000 square ft. of sails. The Great Eastern was begun in 1854 and launched in 1858 from the Isle of Dogs, near London. Figure **9** shows a side view of the vessel, and **10** a midship cross section. In many respects this wonderful ship led the way in naval architecture. In some directions she was so much ahead of her time that it was not until many years after that her lead was followed. In some points this has not been done to this day.

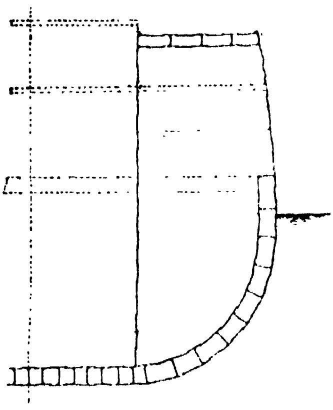
Difficulties in the Construction of Large Vessels. The construction of a large ship involves far more difficulties compared with that of a small one than does the building of a large house compared with that of a small one. For every increase in size greater power is required to maintain the same speed, and consequently greater coal capacity, etc. But the most serious question is that for every increase in size you need relatively more structural material if the same strength is to be maintained, and where no experience has been gained, it is always a difficult problem to determine what will be sufficient strength under the new conditions.



9. SIDE VIEW OF THE GREAT EASTERN

The mere creation of a huge structure is not in itself a particularly praiseworthy achievement. To be that it must be done by efficient means, as was the case in the Great Eastern. The design of her structural arrangement was a greater work of genius than even the conception of the primary idea of building a large vessel capable of steaming to India without coaling. From the very beginning of the structure all old-established conventions were departed from. The keel proper, as fitted in wood ships and as retained even until quite recently in large steamers, was dispensed with, and in its place was fitted an ordinary strake of outside plating only ¼ in. greater in thickness than the remainder of the plating, and stiffened internally by a vertical plate, all as has but recently become the usual practice.

Cellular Construction. The boldest innovation was the entire dispensing with the ordinary floors and frames as the means of stiffening the outside plating, and the introduction of a series of longitudinal girders, as shown in the section [10]. Brunel rightly realised that the longitudinal strength would be by far the most important in a vessel of this description, and he therefore chose not to rely only on the outside plating for strength in this direction, but he arranged the stiffening of this plating in such a way that it assisted in the resistance to longitudinal bending. Moreover, he realised the immense strength of the cellular construction, and adopted it both for the bottom of the ship, where it has now become universal, and for the upper deck, where it has not been adopted since.



10. GREAT EASTERN MIDSHIP CROSS SECTION

The fitting of an entire inner bottom, thereby adding to the safety of the ship, was also a new idea which has now been practically universally adopted. The possibility of using the space between the two skins for the purpose of carrying water ballast was also recognised. The double bottom was in the Great Eastern extended up the side of the vessel to above the water-line, whereby additional safety was ensured. Besides the inner bottom the vessel had twelve transverse watertight bulkheads and two longitudinal ones, which added to the general strength of the entire structure, and lessened considerably the chances of sinking in case of injury. The deck giving the greatest amount of transverse strength was the one fitted at the head of the double bottom, or near the water-line, and the deck possessing the greatest amount of longitudinal strength was the one fitted at the top of the structure. Brunel thereby recognised a principle which it has taken a couple of generations to appreciate fully. Throughout the entire ship the clumsy use of individually thick plates was avoided. The necessary strength was obtained, in spite of the size of the structure, by a thickness of only ¾. in. for the entire inner and outer shell plating, and ½ in. for the deck plating.

Great Eastern Not Exceeded till 1907. To realise what the successful building of such a ship meant at that time, it must be borne in mind that the length, the breadth, and the depth were practically double the corresponding dimensions of the vessels with which experience had been gained up to that time. Throughout the fifty years which have elapsed since its construction there has been a steady increase in the dimensions of ships, but no individual ship has to this day reached the size of the Great Eastern. Two vessels are, however, now building which will exceed in dimensions in every respect those of the ship of 1858, but the engineering feat of producing a ship some six times the size of the largest existing ship is not likely to be ever again achieved in the progress of naval architecture. Unfortunately, the time was not ripe for the profitable employment of ships of such size, and the result was that the Great Eastern came to be a very costly experiment, technically a success, but financially a failure.

HOW TO USE THE INCUBATOR

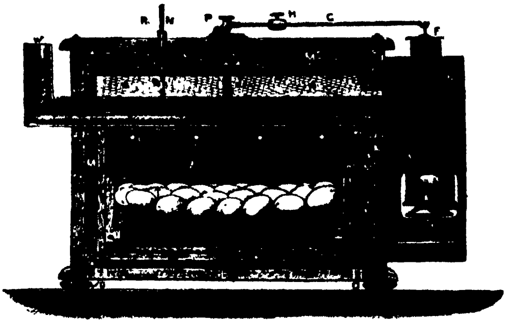
continued from page 5094

A Description of the Incubator and the Method in which it Should be Used. Some Experimental Statistics. Keeping a Record

By Professor JAMES LONG

THE difficulty of obtaining hens for sitting during the winter season, and the perfection to which the incubator has been brought, has resulted in the very general adoption of this machine for the purpose of hatching eggs. A well-constructed incubator is of great service to the poultry keeper, enabling him, as it does, to be independent of the hen to hatch chickens in large batches with almost absolute certainty, without the interference of vermin, or the necessity for outdoor work in bad weather.

Where to Keep the Incubator. There are, however, certain conditions which it is essential to observe. The apartment in which the incubator is placed should be one in which it is not possible for the temperature to fall below, say, 45° F., or thereabouts, at any time. It must be thoroughly ventilated, pure air being practically as essential to the vitality of the egg as to the living chicken. The larger the number of incubators employed in an apartment, the greater the importance of these conditions, especially as where several lamps are burning, there is a larger consumption of oxygen, and a greater liability to smells.

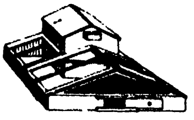


63. HEARSON'S INCUBATOR

a. Tank of water *b.* Movable egg-tray *c.* Water-tray *d.* Holes for fresh air *e.* Ventilating holes *f.* Damper *g.* Lever *h.* Lead weight *k.* Slips of wood *l.* Lamp chimney and flue pipe *m.* Non-conducting material *n.* Tank thermometer *o.* Needle for communicating the expansion of the capsule *s* to the lever *g* *p.* Milled-head screw *r.* Filling tube *s.* Thermostatic capsule *t.* Petroleum lamp *v.* Chimney for discharge of surplus heat *w.* Chimney for discharge of residual products of combustion *x.* Glass chimney, covered with asbestos. The overflow tube is the upper one, on the right-hand side of incubator, and the lower tube is for emptying the tank

Whatever machine be purchased, the instructions of the manufacturers should be carefully studied, and every detail mastered before valuable eggs are placed within it. Among these details, the management of the lamp, and of the drawer, as well as of the ventilation of the eggs, should be specially noted.

In marking eggs, it should be remembered that they are chipped by the chicken within, at the large end through which the youngster emerges, although occasionally they are chipped elsewhere, when it may be necessary to render slight and very gentle help. The chickens hatch on the twenty-first day, but it frequently happens that eggs are chipped on the twentieth day. In the case of the duck, the goose, the turkey, the guinea fowl and the peahen, 28 days are occupied in incubation.

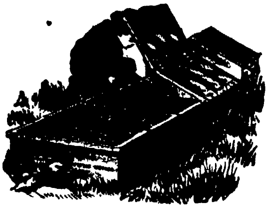


62. BROODER AND COVERED RUN

We proceed to describe the way to manage the incubator on the basis of the experience of one who has achieved much success with it.

Practical Management of the Incubator. When deciding to use an incubator, start, if possible, with a good one, such as Hearson's [63]. If the incubator be bought at a sale, thoroughly examine and test it; afterwards overhaul and clean inside and out, placing it out of doors to dry and sweeten. Obtain a good thermometer, and replace all missing parts, including the canvas in the egg drawer, and the damper if that is necessary. The capsule must not be forgotten, this being, perhaps, the principal item, for the proper working and regulating of the incubator depends upon it. Place the incubator in a small room, if possible, where it will be free from draughts, concussion, or the banging of doors. Having everything ready for a start, fill the tank with slightly warm water, and the lamp being filled and trimmed, light it and carefully watch the thermometer, controlling the heat by the aid of the regulator.

Temperature Necessary. Now keep the temperature even for three days—say, from 100° F. to 103° F.; it should at no time be allowed to rise beyond 105° F. or to fall below 98° F. The germ in an egg will bear a low temperature better than a high one; it is, however, wonderful what eggs will go through and permit the chickens to survive, although it must necessarily weaken them when the temperature is frequently "up and down" during incubation.



64. OUTDOOR BROODER WITH RUN

Place the eggs in the drawer, after marking each with the date on one side and a cross on the other, the date being upwards, then carefully close the drawer and watch the thermometer, and it will be noticed that the temperature will steadily fall, until the eggs begin to

get warm. The incubator must be watched with great regularity, the eggs turned morning and evening, cooled and aired, turning being essential to prevent the germ being fixed, as it were, and thus arresting or entirely preventing development; it also makes up for any little differences of temperature which exist in the egg drawers. The eggs should be exposed to the air for about ten minutes in cold weather, or twenty minutes in very warm weather. They should be handled gently and the worker should be careful not to open the incubator more than twice in the day, especially when the chickens are nearly ready to hatch. The lamp must be filled and trimmed daily, and the tray and damper occasionally examined.

Examining the Eggs. On the seventh day the eggs should be examined, using a lamp with a strong light to ascertain if they are fertile. Thick, or dark-shelled eggs are sometimes difficult to test; in such cases, they may be left a few days and examined again. If there is still uncertainty about an egg, it may be marked, and its progress watched and compared with the rest. After thirteen days, the chicken develops rapidly, and by the twentieth day the egg is almost entirely opaque. The chicken may then be seen to move, and one may hear it tap the shell, and even chirp within.

The eggs intended for an incubator should be fresh, not more than seven or eight days old, ten being quite a limit; very large, very small, or badly-shaped eggs should be rejected, while hens' eggs are preferable to those laid by pullets.

Foster-mothers and all other necessaries should be well examined and cleaned, plenty of fresh sand being used for the floors and runs, of which we give examples in 62 and 64.

Some Results of Scientific Observations. There is very little data existing upon which absolute reliance can be placed as the work of scientific observation. Brief reference, however, may be made to the demonstrations by Mr. Edward Brown, F.L.S., the lecturer who is in charge of the poultry farm of the University College, Reading. Mr. Brown worked six incubators, all of different types, for twelve months, in a specially constructed house, where the conditions as to equability of temperature and ventilation were specially favourable. The machines employed were both of the tank and the hot air types, and during the twelve months referred to there were 89 hatchings, 7,790 eggs having been placed in the machine, of which 6,330, or 81 per cent., were fertile. The number of birds, chickens, and ducklings hatched was 4,631, or 73 per cent. It was found that fertility was lowest in February and highest in November, whereas the hatching results were highest in September, and lowest in August. The variation in the percentage of fertile eggs hatched from month to month was considerable. In August the figure reached 64 per cent., in September 83 per cent., while as regards the hatching of fertile eggs in the various machines, the highest, 94½ per cent., was in a tank machine, and the lowest, 34¾ per cent., in a machine of a similar type. It is indisputable that while in eight months of the year the highest results were obtained from the tank machines, the hot air machines took the leading position during the remaining four months. There is apparently little difference in the results where machines of various sizes are compared, for while a small machine of 50-egg capacity gave a percentage of 79½ fertile eggs hatched, a 360-egg machine gave 76½. In neither case, however, were so many eggs submitted to test as in machines of medium capacity, the largest number being placed in 100-egg and 120-egg incubators, and in these the hatchings reached 71 per cent.

The figures in the table, which are a summary of results obtained from incubators at the College Farm, will afford most valuable information to those who propose to adopt artificial incubation.

The incubator worker is advised to keep a record, and we have, with slight alteration, supplied an example form which has recently been published in the "American Agriculturist."

SAXOPHONES & TROMBONES

Construction of the Instruments. Open and Closed Notes. Position. Scales and Exercises. The Cost

By PAUL CORDER and ALGERNON ROSE

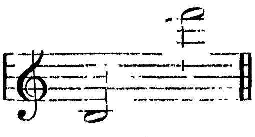
THE SAXOPHONE

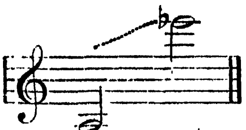
The saxophones, called after their inventor, Adolphe Sax, form a group of instruments resembling in some respects the clarionet; but their tone is more powerful and better suited to the open air. They also differ materially in construction. They are chiefly used in military bands, but have lately found their way into the concert orchestra, and when well played are capable of producing a fine tone.

Saxophones are made in six sizes, of varying compass:

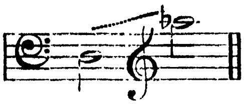
The sopranino saxophone in E♭, soprano saxophone in B♭, alto saxophone in E♭, tenor saxophone in B♭, baritone saxophone in E♭, bass saxophone in B♭. The first and last are but seldom met with. There is also a similar series of six made in F and C, a tone higher than the corresponding instruments in E♭ and B♭, but they do not appear to be much in use.

In order to facilitate matters for the performer, and to enable him to play on any of these instruments without the necessity for learning twelve different fingerings, a uniform notation has been adopted for all sizes of saxophone. This assumes the compass of each instrument to be irrespective of the real sounds, whereas those shown above are the actual notes produced only on the soprano saxophone in C. For the four instruments chiefly used, the notes below will produce these sounds:

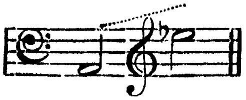




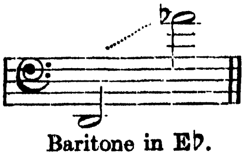
Soprano in B♭.



Alto in E♭.



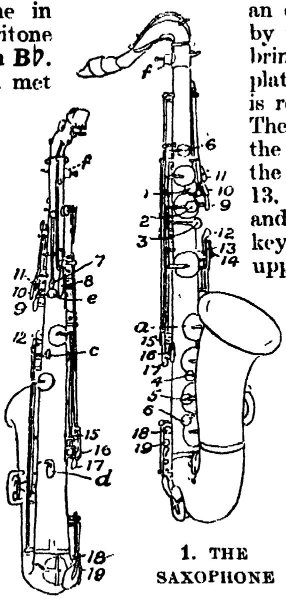
Tenor in B♭.



Baritone in E♭.

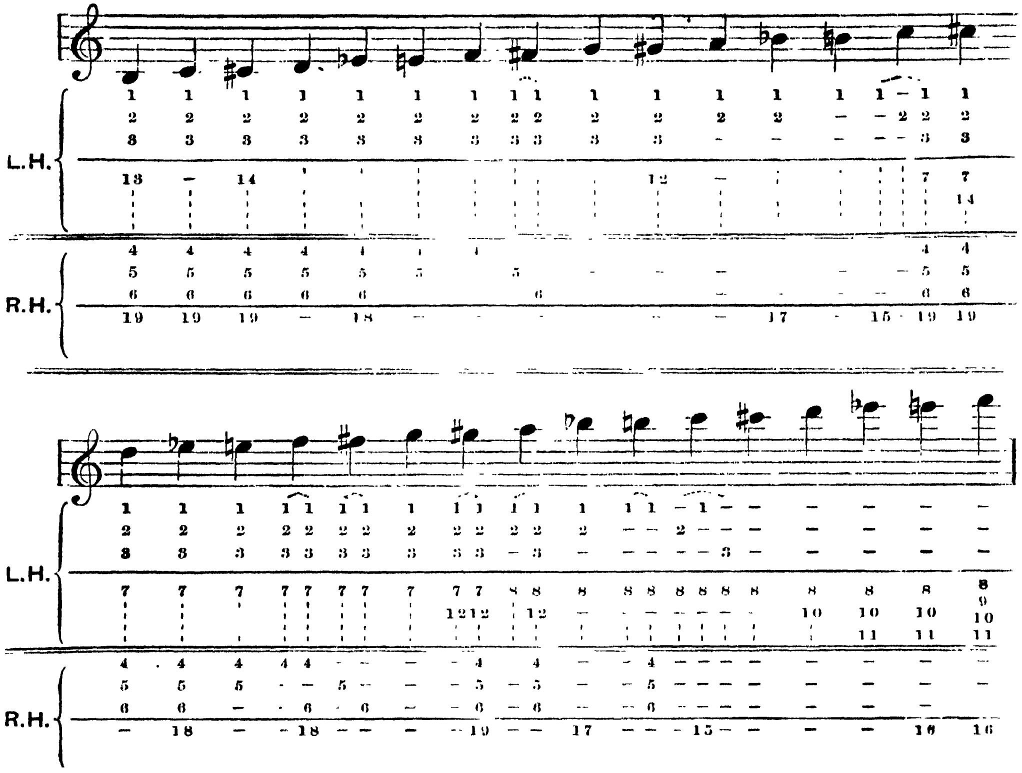
This statement is not strictly correct, for, as will be explained later, the two highest notes can only be obtained on the contralto and tenor saxophones.

The shape of the saxophone will be seen from the illustrations, which represent a B♭ tenor instrument. It consists of a conical metal tube with about 20 lateral holes, which are covered and uncovered by means of a series of levers and finger-plates. The mouthpiece is similar to that of a clarionet, a single reed being employed. With the larger saxophones the weight is partly supported by means of a strap, which is passed round the neck of the player and hooked on to the instrument through an eye [1*c*]. The hook, *d*, is occupied by the thumb of the right hand, which brings the three principal fingers over the plates marked 4, 5, 6. The little finger is ready to depress the levers 18, 19. The left hand clasps the instrument with the three longer fingers on plates 1, 2, 3, the little finger controlling the levers 12, 13, 14. The thumb rests on the plates, and works the octave keys 7, 8. The keys 10, 11 are manipulated by the upper joint of the forefinger and 9 by the middle finger. Levers 15, 16, 17 are correspondingly managed by the upper joint of the right forefinger. The only two keys not accounted for are those marked *a* and *b*. These cannot be operated separately, but work in conjunction with any of the finger-plates of the right and left hand respectively. The fingers must never be held quite straight, but should all be curved slightly, a position which tends to promote agility in passages. The clamp, *f*, is intended to hold a little music-clip for use out of doors. In the table of fingering which follows it will be noticed that many notes can be played in more than one way; to determine which should be adopted will depend entirely on the music, one fingering being more suitable to some particular passage than to others. This matter the student can learn only by experience.



1. THE SAXOPHONE

In the table on the next page the figures 1 to 6, above the line in each hand, represent the keys controlled by the first three fingers of either hand; the figures below the line refer to the extra keys, all of which are numbered as in the illustrations. 7 and 8 are played with the left thumb, 9 by the middle finger, and 10 and 11 by the upper joint of the forefinger, 12, 13, 14, by the little finger. The right hand manages 15, 16, 17 with the upper joint of the forefinger, and 18, 19 with the little finger.



The lines - in the table above indicate that the finger is to be raised from the key it was previously occupying.

This table is to be used in conjunction with the illustrations, the keys being numbered correspondingly. On examining the fingering it will be seen that the primary compass is a little over an octave, but by means of the keys 7 and 8 the whole of these notes are made to sound an octave higher; and the compass is completed by means of extra keys for the last four notes. The top E and F can only be obtained on the alto and tenor instruments, and, with some makers, on the baritone.

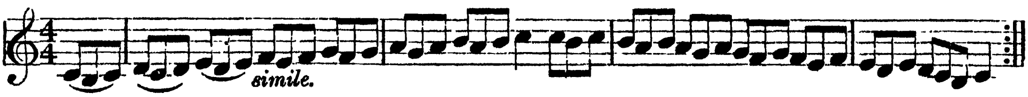
The Reed. The proper management of the reed may give some trouble at first, as the quality of the tone depends mainly on this important matter. The thickness of the reed also has considerable influence on the tone—if too thick it will be loud and difficult to produce; on the other hand, if too thin and soft a weak tone of poor quality will result. The larger saxophones may have a softer reed than those of higher pitch.

The mouthpiece is to be gripped between the lips, which are drawn somewhat over the teeth for the purpose, the reed lying on the lower lip, with about a third of its length in the mouth. The pressure of the lips will vary with the pitch of the note. The tip of the tongue at the end of the reed serves to give an " attack " to notes requiring it. This is called *tonguing*.

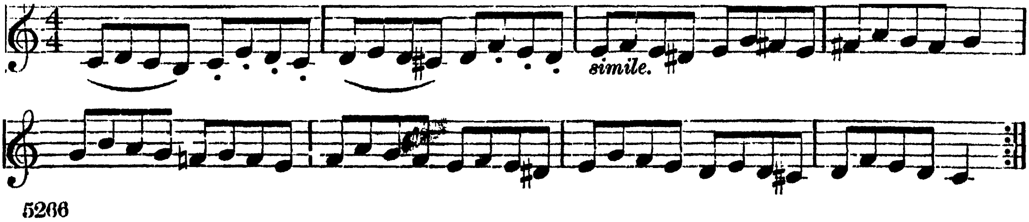
The student should begin with a few simple exercises in sustained notes, endeavouring to obtain an even tone throughout, both in *forte*

Ex. 1.

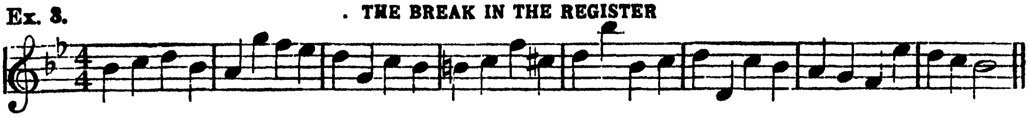
THE LOWER REGISTER



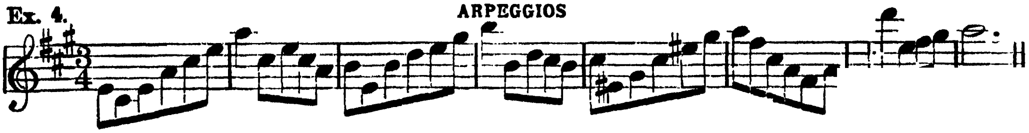
Ex. 2.



Ex. 3. . THE BREAK IN THE REGISTER



Ex. 4. ARPEGGIOS



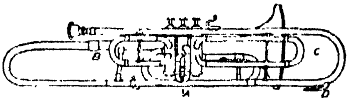
and *piano.* These may be followed by scales and simple passages, played at first slowly and afterwards more rapidly. Slurring two or more notes together and detached notes and simple tonguing exercises may follow. As soon as familiarity is acquired with the fingering the scales should be studied in every major and minor key, as well as the chromatic scale. A few easy exercises are given here, and the student may construct others for himself on the same plan.

TROMBONES

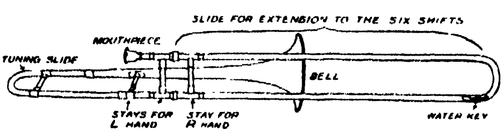
Trombones are of two kinds, those with slides and those with valves. The latter, on account of ease in learning and fingering, are extensively used to supplement saxhorns in brass bands.

Valve Trombones. The mechanism of the pistons is the same as that for the baritone saxhorn; the method of tuning being also alike. As band parts are written in the treble clef, the student will find the instructions given concerning the saxhorns applicable to the valve trombone [page 5130]. The valve trombones are strongly made for Army use, in four patterns, the alto in E♭, costing from about £3 10s.; the tenor in B♭, from about £4 4s.; and the bass in G, from about £6; whilst some firms manufacture a special contra-bass in E♭, costing approximately £11. Mouthpieces range in price from 4s. to 7s., whether plated or silver-rimmed; and black or brown leather cases are to be had from £1 upwards.

In Germany, Austria, and other parts of the Continent, brass wind instruments, instead of having pistons, are furnished with rotary-action keys. The touch, it is claimed, is thereby more delicate, and the intonation more accurate. For parade purposes, nevertheless, such mechanism gets out of order sooner, and is more difficult to make right, whereas a piston can be quickly unscrewed, cleaned, and readjusted. Holding the instrument firmly with the left hand, leave the right free, as in the saxhorn, for manipulation of the valves. In the tenor valve trombone, the first note to sound is B♭, second line bass clef, this being the easiest to produce. Avoid attempting to get the upper sounds until the lip has been exercised by scales in the lower register. Practise at first frequently, at short intervals. This will prevent the lip from becoming tired, and ensure more progress than longer study. It is when fatigued that bad habits are usually contracted, and, once acquired, they are difficult to break. Some students, by persisting in trying to run up the high notes of a scale before walking slowly among the low sounds, have spoiled their lips for good playing. If the student does not begin with the low notes and gain power over them gradually, the danger is that too tight a pressure from the mouthpiece at first may partially paralyse the lip-muscles. The main difference in the valve trombone compared with the baritone saxhorn—the fingering is the same—is the ringing sound which the straighter tubing, arranged horizontally, imparts. Unless proportions are exact in internal diameter from mouthpiece to bell, and the brass is of good quality and medium thickness, clearness will be lacking, and the open notes will be neither firm nor satisfactory in timbre.



VALVE TROMBONE
a, b, c. Tuning slides. *d.* Water key



SLIDE TROMBONE (Metzler & Co.)

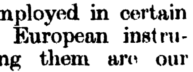
Slide Trombones. The ambitious student, however, will not content himself with the piston mechanism. If he has an opportunity of becoming possessed of a slide trombone, he will soon perceive that for purity and brilliancy of tone it is far preferable to the instrument with valves. Indeed, the slide trombone takes very high rank in the modern orchestra. Although one of the most ancient, it is the most perfect of all wind instruments, and is therefore recognised as the King of the Brass. There is no grander tone than that of a well-played trombone, for it sounds an impressive fortissimo without vulgarity, and the most whispering pianissimo with wondrous clearness. The beautiful qualities of the slide trombone are heard to advantage—as is the case with stringed instruments—in a quartet of accomplished players.

The Trombone Quartet. Formerly, there was a soprano trombone in B♭, playing an octave higher than the tenor instrument. It is still occasionally employed for the interpretation of parts in certain compositions by Bach and Mozart, being used to double or sustain the soprano voices. But, as it is scarcely ever met with in England or France, we confine our attention to the other three members of the family. Of these, the tenor has the best quality of tone throughout the extent of its scale. It is, therefore, given first and second parts; but to make up the trombone quartet the alto and bass instruments are indispensable. These are all alike in pattern, differing only in length of tube, which is divided into two U-shaped parts of cylindrical bore. The first part expands outwards at the bell, and from the portion of the tube opposite the bell projects a brass stay, to which is affixed the mouth-tube, furnishing the

over the two ends of the first U-tube. At the lower end of the slide is the water-key, and at its upper end is the stay, extended by the right hand of the player for the various "shifts." In the bass trombone this stay has a hinged handle, to enable the performer to get the lowest notes. Thus, by pushing out the slide, the air-column can be lengthened with ease, so that, in the E♭ alto, notes in the 6 in. or 4 ft. octaves can be sounded by a simple movement. Likewise, in the tenor and bass instruments, the 2 ft. can alternate with 8 ft. sounds at will.

It is because no fixed points, such as piston-buttons, keys, or frets, regulate the pitch for different sounds, that—as is the case with the violin or the voice—the trombonist must be guided by the musical qualities of his ear. Every shift transposes the instrument a semitone lower in pitch. But if quarter tones are required they can be obtained. As these, and even eighths of tones, are employed in certain Oriental melodies, the only European instruments capable of performing them are our violins and trombones. On all piston instruments, as with the piano and church organ, there is no sensible difference between A♯ and B♭, D♯ and E♭, and so on. On the slide trombone, however, accomplished players give the true enharmonic sounds by moving the slide a little higher up for sharpened notes than they do for those which are flattened.

Compass. The trombones are not "transposing" instruments, but sound the notes as written. Each model has a compass of a little over two octaves, but an octave and a half suffices for the best effects. For the alto trombone in E♭, the music is written in the alto clef, with C on the third line. In this instrument the student should cultivate the higher rather than the lower sounds, as the latter are better played by the tenor instrument. The quality of tone of B (first ledger line above alto staff), C, D, E, and F, is particularly useful. When the slide is closed, the notes in Ex. 1 are obtained



by the lip, without counting the fundamental C♭, which is unsatisfactory.

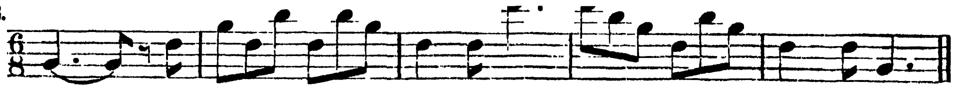
By means of changing the position of the slide, the tone extends from A (below second ledger line) to D♯ (on second ledger line above staff), with all the intervening semitones. The cost of the alto in E♭ ranges from £3.

Tenor Trombone.

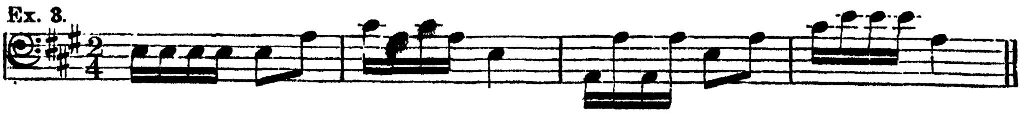
strument of the family, is in written both in the tenor and the bass clef, so the student is advised to accustom himself equally to both clefs, by writing out exercises printed in the bass with the tenor signature, and vice-versâ. The lowest note on the tenor trombone is E, first ledger line below bass staff, and the highest is A♯, over third ledger line above staff. In England the price ranges from about £3 5s. for a well-made instrument. When three tenors are used together, it frequently happens that the music is written in three clefs, alto, tenor, and bass, the first having C on the third line, the second C on the fourth, and the third F on the fifth. This makes the parts easier to read than when many ledger lines are used, as soon as the student has accustomed himself to the clefs. If habituated to the treble clef, he has only to imagine in the alto that every B becomes a C, every C a D, and so on, an octave lower. This operation is reversed for the tenor clef, with middle C on the fourth line. Then every C becomes a B, every D a C, and so on, an octave lower than it would be in the treble clef. By transposing on paper melodies written on one clef into another, the trombone student will soon acquire the necessary knack, so that when he takes his place in an orchestra he will have an advantage over players, perhaps more proficient than himself, who have not given attention to this matter.

The Importance of the Slide. The superiority of the slide over valves will be evident if we compare two instruments, by taking two tubes of equal length, one straight—such as the coach-horn—and the other of the same length coiled up like a bugle. The tone quality of the straight instrument is more ringing, and carries a greater distance. Inevitably, in piston instruments, the extra tubing attached to different valves, when not used, is so much dead weight, impairing the vibration. Moreover, on account of the differing length of the air-column within the tube, if the second piston lowers the sound half a tone, and the third a tone and a half, the additional tubing for the half-tone of the shorter air-column may be true when transposing the pitch of open notes. But its length will be obviously insufficient when added to the tone

Ex. 2.



Ex. 3.



and a half of the longer column opened up by the third piston.

The harmonic series on valve instruments thus sounds too sharp when more than one piston is used. To compensate for the discrepancy a fourth piston is sometimes added in the larger valve instruments ; but in the slide trombone, as on the violin, the player regulates the length of each vibrating segment at will, so that he is able to produce truly almost every harmonic he desires. The slide trombone, and particularly the tenor, is thus more perfect, musically, than any other wind instrument.

First and Second Positions. When the slide is closed the trombone is said to be in the *first position.* In a tenor instrument, as with the open notes on a baritone saxhorn, the following five harmonic sounds result: B♭ (second line bass clef), F, B♭, D, and F above. Later on, when the lip of the student obtains these notes with facility, with a tighter embouchûre, he will get the A♭ and top B♭. At first, however, the lip should never be forced unduly.

Having mastered these sounds, beginning with the B♭, and not resting satisfied till the F above is produced clearly, as well as the octave B♭ and the tenth, with increased tension for the higher notes, the lip may be exercised by changing the order of the sounds. At first it is well to give a separate breath to each note. Play in slow time, counting four on every one sound. Then shorten the duration of each note by counting, mentally, two for every one ; and, finally, get the five notes clearly on the five beats. After transposing the order, triplets and dotted notes may be practised in slow time. Do not attempt double or triple tonguing, nor waste time exercising to get a trill by moving the slide in and out. [Ex. 2].

In different makes of instruments the distance to which the slide should be extended slightly varies for the different positions. Generally speaking, what is known as the "first shift" (analogous to putting down the second piston on the baritone saxhorn) is three and a half inches, or 70 millimetres from the first position when the slide is closed up. This gives the second position.

Attitude. A word here may be said regarding the attitude of the student. His head and body should be erect. The instrument must be grasped firmly without unnecessary movement, keeping the left arm to the side. Although in some instruments the elbows may be kept close to the body, there should be no pressure on the ribs in trombone playing, or breathing will be impeded. The thumb and middle finger of the left hand hold the cross-stay nearest the player, whilst the first left finger hooks itself over the second stay, so as to regulate the pressure of the mouthpiece on the lips. The other two fingers should be bent over gracefully. As regards the right hand, the thumb and forefinger hold the stay crossing the near end of the trombone slide, the fingers being closed and not opened.

When in position the main tube, which carries the bell, passes over the left shoulder, and the slide should be held slightly downwards, as remote positions are then easier to obtain accurately and the strain is less on the upper lip. At the bend of the tube over the left shoulder is the tuning slide, which should be kept in good order. If the pitch of the instrument is too sharp, it can be corrected by slightly pulling out this part. As regards choice of mouthpiece, the student is referred to the remarks made on that subject in the Saxhorns [page 5131–2], as also for the method of blowing. The tongue, however, must not give any stroke before the slide is extended or contracted to the position required to produce the note to be played. It is only by constant practice that the forearm and wrist will move with the necessary suppleness and stop without hesitation at the exact point required. Military trombone players are apt to cultivate a hard, brassy tone, which becomes disagreeable in the concert-room. Having sounded, with the slide closed, the B♭, F, B♭, D, and F above (articulating the syllable "too" by a movement of the tongue as if expelling a bit of fluff from the mouth), by extending the slide to the first shift the harmonic series will be found lowered a semitone in pitch. The low note, therefore, should now be A♮. Get this clearly. Then sound the E above. Next obtain the octave A ; afterwards the tenth, or C♯ ; and, finally, the twelfth, or E. The tone is thus transposed from B♭, with two flats, to the key of A, with three sharps.

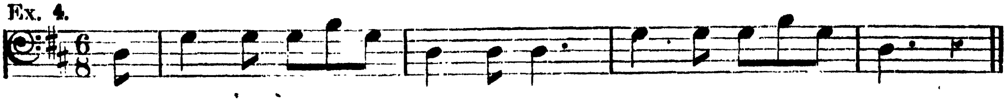
As before, having obtained the five sounds distinctly, change their order, practising the fifth with the keynote, the twelfth, octave, tenth, and so on, varying the rhythm and increasing the speed as the lip gains in flexibility [Ex. 3].

Third Position. By extending the slide about seven inches from the first position, the student gets to the "second shift," analogous to putting down the first piston of the baritone saxhorn. The instrument, therefore, giving as its low note A♭, has now transposed itself from a sharp to a flat key, with four lowering signs—B, E, A, D. The first note to sound is therefore A♭, first space bass clef. Above it comes the fifth octave, tenth, and twelfth from the tonic, or E♭, A♭, C and E♭. Blow these sounds carefully without forcing them, practising the three lower ones before attempting the two higher. Construct exercises on these five notes.

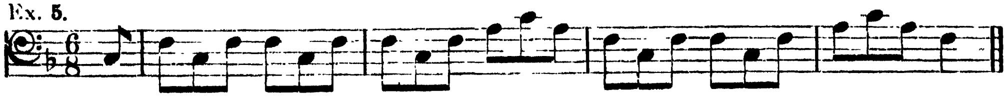
Fourth and Fifth Positions. Extending the slide about 10½ in., the student reaches the "third shift," giving the same sounds as when the first and second pistons in the baritone are put down. The low note is now G♮. So the fourth position brings us into an easy key so far as concerns the reading of notation. Get this low G (first line bass clef) with a full, mellow tone, and then the fifth, octave, tenth, and twelfth above, or D, G, B, and D. In learning the harmonic series on the different positions, the student will find assistance by transposing the different Army bugle-calls into the various keys of the positions. Try the Sergeants' Barrack Call [Ex. 4].

The fifth position is otherwise known as the "fourth shift," and gives the same sounds as when the second and third pistons are put

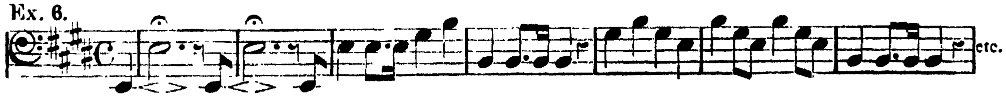
Ex. 4.



Ex. 5.



Ex. 6.



down together on the baritone. Extending the slide 14 in., the low note will now be G♭, or F♯, so that there is a choice of a key with either six flats or six sharps. Sound low G♭, with D♭, B♭, and D♭ above, practising especially the three lower notes till they are sounded with facility.

Sixth and Seventh Positions. Pushing out the slide 17½ in. gives us a fifth shift, with sounds similar in pitch to those of the baritone when the first and third valves are put down. The harmonic series is now in the key of F—a favourite in military music, with one flat, B. Sound low F, with C, F, A, and C above. Try the "Sergeants' Dinner Call" [Ex. 5].

Extending the slide 21 in., we get the "sixth shift," or extreme position, as when all three pistons are down on the baritone. This lowers the sounds from F to E♮, so that the key has now four sharps instead of one flat, the low note being E, first ledger line below bass staff, and not E♭, as is sometimes written by composers. Sound the low E, with B, E, G♯, and B above, practising, with the first, the intervals of a fifth, octave, tenth, and twelfth. As an exercise, we give the opening bars of the "Last Post" [Ex. 6]. For a shilling, the student can get all the Army bugle sounds. If he does this, he will observe that, as the calls are written in the treble clef in C, for this position he has merely to obliterate that clef and add four sharps, and the notation is precisely the same for the bass. For the sixth shift, he thus has plenty of exercises admirably adapted for familiarising him with the correct sounds and articulation of the five notes.

Inserting Thirds. Knowing that this is a chromatic instrument, the student, noticing the skips in each series from the keynote to the fifth, from the fifth to the octave, and thence to the tenth and twelfth above, will be eager to understand how the missing sounds are filled up. If he endeavours prematurely to attack the chromatic scale his mind will become confused. He must be content, therefore, not to rush at the problem, but to master the instrument gradually. That interval most required is the third. If he inserts this neatly in each series, meanwhile, he will be going in the right direction. Having closed the slide and returned to the first position, a third above B♭ is D. This, it will be remembered, is the second note in the fourth position, or third shift, or a fifth above G. Sound the B♭. Then advance the slide 10½ in., so that the D is given clearly. Play these two notes slowly in succession and gradually quicken the pace. Sound the low B♭, following it by D, in the third shift; return to the first position, sounding F, B♭, and D above, the second D being in the first position. Then descend the series in like manner, extending the slide accurately for the lower D. In the same way, the missing third in the second position will be sounded by extending the slide to the fifth position; that lacking from the third position by expanding the tube to the sixth; that absent from the fourth position will be obtained from the seventh; that missing from the fifth will be found in the first; the third absent from the sixth sounds on returning to the second; and the third which cannot be produced in the seventh is elicited on coming to the third.

When once the mind of the student grasps the idea of the principle governing the manipulation of the slide for the insertion of the thirds, he has practically filled up the whole diatonic series of notes for the performance of all the major scales. But he must work first on the thirds, constructing exercises to familiarise himself with the most usual shifts. A little thought will enable him to do this. If ingenuity lacks, many cheap instruction books may be obtained. These, however, usually give the exercises without the explanation which a master is supposed to supply. Nevertheless, the best teachers have been the readiest to recognise the importance of self-culture and of stimulating the student to acquire knowledge by the active exercise of his own faculties. Mere passive perception of details of knowledge may answer average requirements, but the best master in the world cannot make a good musician if the student shrinks from using his intelligence.

Scale of B♭. Get the low B♭ in the first position. Use the sixth for C♮, this being the second harmonic in that series. Now slide to the fourth position for the D, and the third for the E♭. F♮ is obtained in the first position. So far, except the first, the notes have all been second of their harmonic series. With somewhat more tension on the lip, get the G on putting the slide in the fourth position and sounding the third harmonic of that series. Then get to the second position for the A, produced equally on the sixth, but with a tighter lip. For the B♭, return to the first position or go from the sixth to the fifth. C is sounded in the third or the sixth position. B♭ is obtained in the first or fourth. E♭ is the fifth sound in the third position or the sixth in the sixth position.

Finally, F♮ above is the fifth sound in the first position, the seventh in the sixth, or the sixth in the fourth. Return in the same way, and when low B♭ is reached, the A beneath it can be obtained in the second position, the G in the fourth, and the F in the sixth. Then return to the B♭ to complete the scale.

C Major. The first note, second space bass clef, or first space below tenor staff, is obtained from the sixth position. D above is the second sound in the fourth position. E♮ is obtained in the second position and F in the first. G is the third sound in the fourth position, A the third in the second, B♮ the fourth in the fourth position, C the fourth in the third, D the fourth in the first, E the fifth in the second, F the fifth in the first, and G the sixth in the fourth. This is as high as the student should attempt. Return in the same way.

The Relative Minor. Write out the foregoing exercise both in the bass and tenor clef, putting the numbers of the positions over each note. If we now take A minor, the low sound in the second position gives the first note. Extend the slide to the seventh position for the B, which is the second sound in that series. Then bring the slide to the sixth position for the C above, to the fourth for the D, and the second for the E. For F♯, extend the slide to the fifth, that being the third note of the series, and bring the slide to the third position for the G♯. Draw it to the second position for A♮, and extend it to the fourth for the B. The third position will then give the C, the first the D, and the second the E. That is the limit. Returning, sound the top E, D, C, B, and A as before. Now G♮ will be the third note of the series in the fourth position, instead of G♯ in the third, while F♮ is the second sound in the first position instead of the third in the fifth, which gave F♯ Get the E, D, C, B, and A as before.

The instructions given for cleaning saxhorns apply equally to the trombone, but the simplicity of this instrument renders it much more easy to keep in order. The water-key should be used to let out the moisture condensed with the breath at intervals during playing. On conclusion of practice the slide tube should be detached and inverted. Unlike the violinist, the trombone student has no strings to adjust, nor has he, like the clarionet, oboe, or bassoon player, any reeds to trouble him, nor keys to clean.

BASS TROMBONE

This instrument extends the compass of the tenor four semitones downwards to C♯, second ledger line below bass clef. Its great value is that, in sustaining chords, the slide instrument is distinguished by remarkable depth of power and sonorousness impossible to obtain from the smaller members of the same family. As the tube is longer and the instrument heavier, the student who takes up the bass trombone ought to be strong-chested and strong-lipped. The manner of holding the bass trombone is similar in method to the attitude described for the tenor; but for extreme positions the right hand manipulates the handle, which is hinged to the stay at the top of the slide. Be careful, on account of the weight of the instrument, that the grasp of the left fingers on the other stays is firm, so that the mouthpiece may not be jerked from the lips, and the embouchûre upset, by undue thrusting forward of the slide by the right hand.

The Seven Positions. As in the tenor or alto so in the bass trombone, there are seven positions or six shifts. In the G trombone the instrument is in the first position when the slide is closed, analogous, in an instrument with pistons, to the open notes of the latter which sound when no valves are used, with this result: G (first line bass clef), D (third line), with G, B, D, F, and G above. On the long tube, therefore, seven harmonics, the last giving the double octave from the low G, can be produced by tightening the lips after a fair amount of practice.

On a G valve trombone the pitch is flattened a semitone, throughout the harmonic series, by pressing down the second piston; or when the slide is moved forward 4½ in. the result is the same, as we then have the last-mentioned notes preceded by flats. This gives the second position. Write out each position on paper.

On a piston bass trombone, the open pitch is flattened (for the third position) a whole tone by pressing down the first valve. On a slide instrument, move the stay about 9 in. from the first position. The harmonics then obtained are F (below bass staff), with C, F, A, C, E♭, and F above.

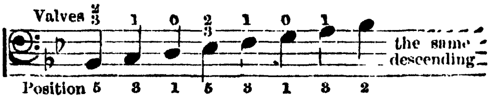
By pressing down together the first and second pistons, or the third alone, a G valve trombone is flattened a tone and a half. On a slide instrument, extend the stay about 13½ in. The resultant tones are then E (first ledger line below staff), with B, E, G♯, B, D, and C above—the fourth position.

Fifth Position. Depress the third and second pistons together. This flattens the G valve trombone two whole tones—the fifth position. Extend the slide—on an instrument without valves—about 17½ in. The harmonics then obtained are similar to those of the last position preceded by flat signs.

Putting down first and third pistons together, the pitch of a valve instrument is lowered two tones and a half—the sixth position. Without valves the slide must be extended 21¾ in., the harmonic series elicited being D (below first ledger line), A (a fifth above), D (an octave above), F♯ (a fifth above), A (a twelfth), C (a fourteenth), and D (a fifteenth from the tonic D). Thus it will be observed how in cylindrical tubing the harmonics sound closer together as the pitch ascends and each vibrating segment diminishes in length.

To get the instrument in the seventh position, simultaneously depress the three pistons. This flattens the instrument three whole tones, thus: One tone by the first valve, a tone and a half by addition of the second, and another tone and a half with the third down, or three together. This effect, however, is produced more truly on

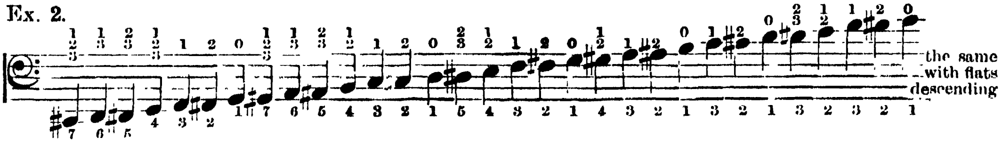
Ex 1.



a slide instrument by extending the stay, with the handle, a distance of 26 in. This is 5 in. more than was necessary on the tenor. The notes last mentioned are now flattened a semitone, so that the lowest sound, D♭, gives the enharmonic C♯, or bottom limit to the compass of the trombone family. In actual playing, except for its two pedal notes, this position is seldom employed.

Diatonic Scale. Having begun with the pistons up, or the slide closed, and obtained clearly the harmonics in the first position, then, having practised the shifts without tiring the lip with the upper notes—especially in the fourth, fifth, sixth, and seventh positions—the student must endeavour to master the scale of B♭ major. We give it with the fingering above the staff for the G valve trombone, and with the positions marked underneath for the slide instrument [Ex. 1].

Ex. 2.



Intervals. The manner of inserting thirds in the tenor slide trombone equally applies to the bass instrument. In addition to thirds, the student, however, should familiarise himself with other intervals. At first, every such exercise should be practised slowly. If the scale of B♭ major is taken, B♭ (second line, bass clef), as we have seen, will be sounded in the fifth position. Return to the first position to obtain the D, a third above. C (second space) is easily sounded by the slide resting midway in the second position. In exercising the lip, get, therefore, the intervals of seconds and thirds in succession by playing clearly and softly B♭, C, D, and B♭. Before proceeding to treat the second degree of the scale in the same way, take a fresh breath. Sound C, as before. Get the third above (E♭) by putting the slide in the fifth position. Connect the two intervals by the D, with the slide close up, and return to the C. Again pause.

Proceed to the third degree. Sound the D as before. F (a third above) is obtained by the third position. To insert the E♭ between these notes, extend the slide to the fifth position. Then return to the D. Take a fresh breath and start again on the E♭. Get the G, a third above, by bringing the slide to the first position. Insert the F, and return to the E♭. Next, try the F (third position), following it by the A above (also in the third), but insert the G by closing the slide in the first position. Take a short rest before striking, with a firmer lip, the G on the fifth space. Get the B♭, a third above, by extending the slide to the second position, and insert the A by going to the third. There is no need for the beginner to proceed beyond the B♭. Intervals of fourths, fifths, sixths, sevenths, and octaves should be treated in similar fashion.

Chromatic Scale. Transpose the scale above on paper into the other major scales. Mark the fingering of each note, or the position, by referring to the particulars already given. But, in order that the student may be able to play correctly the keys containing sharps or flats not yet mentioned, as well as minor scales, we give the fingering for the valves, and positions of the slide, for the chromatic scale throughout the entire compass, using sharps in ascending and flats in descending [Ex. 2].

Amongst the great composers who have given most prominence to this wonderful family of instruments may be mentioned Wagner, Strauss, Gluck, Beethoven, Rossini, and Mozart.

The Cost. According to the quality and the particular make, so the price of a G trombone varies, but a good bass instrument may be obtained from £3 10s. upwards. On account of the extra mechanism, a valve instrument costs from £5 upwards. Mouthpieces and cases are similar to those for the tenor.

WHERE TO LIVE & BE HEALTHY

Effect of Climate and Soil on Health. Surface Soil and its Bacteria. The Hygiene of Soils. Good and Bad Sites for Houses

Group 25
HEALTH
19

Continued from page 5196

By Dr. A. T. SCHOFIELD

THE cooling of the molten part of the earth's surface produced the igneous rocks, while the rain and decomposition due to weather produced the sedimentary rocks and soils. Among the igneous rocks we may include lava, basalt, granite, etc. Among sedimentary—or aqueous, as they are rightly called—we may include sandstones, greensand, limestone, chalk, gravel, clay, and the soil itself, as surface or subsoil.

What a Pound of Earth Contains. Surface soil is largely an organic composed of decaying vegetable and animal matter. The subsoil is composed of inorganic debris of rocks only. Soils are constantly moved up and aerated (like currents of air) by the labours of earthworms, moles, ants, etc.

The surface soil is so full of bacteria that it is calculated there are some 500,000,000 in every pound of earth. These have the power readily to decompose organic matter into nitrates, nitrites, ammonia, carbonic acid and water.

Vegetables, unlike men, cannot assimilate nitrogen from complex bodies, but only when these are split up.

Certain vegetables (legumes and cereals) can get their free nitrogen, without ammonia or nitrafication, by means of bacteria that form nodules and colonies in their rootlets, and supply it to their hosts. They have to be fed with a carbohydrate, and fix the nitrogen in proportion as they use up the former. *Nitragen*, as these microbes are called, is sold for fertilising grain and bean crops. No less than seventeen different solutions of germs for seventeen varieties of crops are made and sold at 2s. 6d. per bottle, two bottles fertilising an acre, and enormously increasing the yield. Earth entirely freed from bacteria is sterile and will not nourish plants.

The pathogenic or disease-bearing bacteria common in the soil are those of tetanus or lockjaw (very common in garden mould), typhoid, glanders, anthrax, and cholera. The surface soil is thus a great laboratory for germs and worms.

The Effect of Soils on Health. Clay produces rheumatism, catarrhs, neuralgia; alluvial soil, malaria; gravel and chalk are excellent for health. Old Swindon is on limestone and sand, and New Swindon on heavy clay. The cases of measles in New Swindon are 20 to 1 compared with the other town, and chest diseases are one-third more. The looser the soil the higher the temperature, and the frost does not strike so deep.

Air in the soil varies according to the soil In sands it may be as much as 50 per cent. It generally resembles the air above, but, inasmuch as the composition of the air is variable, being a mixture and not a compound, it is not exactly the same. It is always more impure, the oxygen is less and the carbon dioxide is more with the increasing depth of the soil from the surface. The proportion of nitrogen remains constantly in the same proportion as in the atmosphere. The excess of impurities and carbon dioxide in the ground air is so great that it is dangerous to let it enter the house, as it does at times. The carbon dioxide always increases after rain.

Ground air moves by temperature, pressure, rain, and subsoil water. After heavy rain it may be forced out in dry places such as basements, and so enter the house. Besides this, dwellings are warm, and thus suck the ground air in. Gas has been known to be drawn into a house from a burst pipe 20 ft. distant through the soil.

Water in the Soil. The moisture in the earth at certain depths, increasing to saturation, forms a continuous sheet of water at from a few inches to 100 ft. below the surface. Above this level the soil is kept moist by rain; below this level by capillary attraction and the evaporation of the water below.

Subsoil water is always slowly moving towards some outlet. Rising subsoil water is dangerous, as it forces the air out of the soil and leads to the possible pollution of shallow wells by connecting them with neighbouring cesspools. Falling subsoil water leaves the soil moist and full of air.

All soils hold water in proportion to their permeability and absorption. Their permeability is the speed of percolation through them; clay is the slowest; chalk, greensand, and sand the quickest. Below is a table of the absorption of water in soils.

	Per cent.		Per cent.
Granite	·1 to ·4	Sandstone ..	3 to 8
Slates	2 „ 10	Chalk	15 „ 20
Limestone ..	5 „ 10	Marl and loam ..	30 „ 50

Moisture in soil increases with the amount of organic matter. If the subsoil water be within 5 ft. of the surface it is injurious to health.

In summer there is little percolation. The ground water begins to rise in November, and reaches its maximum about March, decreasing towards the summer.

A permanent level of subsoil water is much better than one that fluctuates; and a low level is best. The level of subsoil water can be tested by cups fixed in a rope in the well. Uniform depth of water in a well shows the level of subsoil water. The rise and fall of the water was discovered by Pettenkoffer to be the cause of typhoid in Munich.

To lessen and carry it off there require to be large, porous drainage pipes laid 3 ft. below the surface and 6 ft. apart—quite distinct from all drainage. Damp soil signifies air and water; ground water means all water and no air.

Loose sand holds 2 gallons of water per cubic ft. Sandstone holds 1 gall. The subsoil water in Austria moves up and down with the Danube, though it is three-quarters of a mile away.

Sites for Houses. A good site requires pure air, no dust, level ground, sunshine, an even temperature, and no strong winds, and should be away from motor-haunted highways or byways. Valleys should be avoided and depression and pockets on levels. A slight elevation is good—on the spur of a hill or terrace. Houses should not be built under the side of a hill. The soil and subsoil should be examined; there should be no gravel pockets on clay, which are always very damp. Clay with sandstone is good. Peat and organic refuse, "made" and alluvial soils are bad. Sandstone and gravel is often damp—limestone is best. Soil made up of "shot" rubbish should never be used.

The side of a hill is, of course, warmer than the valley, because while the warm air rises the cold slides down the hill. In a valley the fogs lie and the frosts are always keen. There should always be shelter from the prevailing wind of the district.

There should be free circulation of air, sheltered from the north and east by rise of land or belt of trees. The site should not be near a brickyard or graveyard, or a sewage farm or infectious hospital. The worst site is a hollow of bad gravel on a clay substratum and high subsoil water; the best is at the top of a slope on sand or gravel, with low permanent subsoil water. A site on the banks of rivers is not very healthy. Porous soil is best, and, next to that, rocks, granite, clay, chalk. Subsoil water is best 15 ft. below the surface, but should not be less than 10 ft.

Three points should be remembered—the aspect and exposure to wind, sun, and air, the nature of the soil, and the surroundings.

The amount of sunshine received in a room facing east is five hours in the morning, excepting in winter; facing south-east, eight hours in the summer, and three in winter; facing south, from 7.30 a.m. to 4.30 p.m.; facing south-west, from 10.30 all day; facing west, from 1.30 all day.

Warm Climates. We now turn to the question of climate. A warm climate has a temperature of from 80° to 84°, and produces sunstroke, cholera, yellow fever, etc. A temperate climate has a temperature of from 50° to 60°, and produces ordinary English diseases. A cold climate has a temperature of from 32° to 40°, and produces scurvy.

Warm climates are good for people suffering from lung diseases and rheumatism; hot climates for abdominal diseases; cold climates for lung diseases. Continental climates (as Asia) are cold, and the West wind is cold and South hot. Insular climates (Europe) have a mild West wind and cool South. Mixed climates (North America) have a cold West wind and a cool South. Hot climates enervate, because the tissue changes are so slow; one is more healthy where they are rapid. The most unhealthy climate is that on the coast in the tropics. Tropical climates are very much more unhealthy than they need to be, on account of the effect which heat has on filth.

Humidity in the air increases the effect of hot climates and lessens that of cold, because it retards the evaporation.

In a very dry climate evaporation is too great. In health, 75 per cent. of saturation in the air is best. The wind increases the evaporation. For people between 40 and 80 years of age, the colder temperature is the more healthy.

The Healthiest English Climate. A hot summer and a high death rate go together. A rise from 58° to 62° in summer will often bring on an increase of 15 per cent. in the death rate. The healthiest permanent English climate is from 50° to 55° F. Europeans do not flourish when the mean temperature is 20° above our own. Cold that may be well borne in health cannot be borne in sickness or old age, but in phthisis is well withstood.

Shade heat is worse and harder to bear than sun heat. If the sun heat be 120° the shade will be 90°. Winds also affect climates; the Föhn, Mistral, the Sirocco, and the East wind are examples of this.

The climate of the sea is equable, while that of continents is unequal. Drainage raises the temperature by drying the land. All vegetation increases humidity and tends to lower temperature. The electrical state of the atmosphere is also a factor in climate.

Warm climates are of three sorts—humid, as Madeira; moderate, as New Zealand, Great Britain, Algiers: dry, as the Riviera and Australia.

Island and shore climates are the purest and best and are full of ozone. They are excellent for convalescence, scrofula, and depression, but not for irritable nerves.

Climate by the Sea. Ocean climates are good for lung diseases. England, with a range of temperature of 20°, is most healthy.

On the shore, the breeze is generally from the sea from sunrise to sunset, because the land radiates heat quicker than the water. It is from the land from sunset to sunrise because the earth cools more quickly than the sea.

In districts near the sea there will be a great rainfall, no dust spores, but light variable winds. It is good for residence, and increases the expansion of lungs and the rapidity of tissue changes. It is good for phthisis, overwork, general convalescence, and as a prevention of cholera. It is not good for bronchitis, heart disease, chronic rheumatism, or old age.

The climate of woods and forests is cool but equable and sheltered, and is good for chronic bronchitis, heart disease, and irritable nervous diseases.

Desert climate, as at Helouan and Assouan, is good for chronic rheumatism.

The vital activity varies with the season of the year. In winter and spring respiratory diseases are rife; in winter the vital activity is at a maximum; in spring it is at a maximum and decreasing; in summer it is decreasing to minimum; in autumn it is at minimum and increasing; in summer and autumn digestive diseases are most rife.

PORTABLE MACHINE TOOLS

The Advantages of Portable Machine Tools. Floor-plates. Portable Machines of Reciprocating and Rotary Types

MACHINE TOOLS
continued from page 5216

By FRED HORNER

THE machine tools which have been previously treated are all of fixed type—that is, they are fastened down to the flooring of the shop or upon special masonry or concrete foundations. In all such cases the work has to be taken to the machines to be tooled.

There is another important class of machines, the use of which is rapidly increasing, that of the *portable* types, which may be carried about anywhere and set to work on massive pieces, or upon light jobs. Two main reasons may be cited for the employment of such machines. In the case of very heavy castings or forgings, it is often inconvenient and costly to move them about the shop to the different tools, and difficult to adapt the latter to operate suitably; and on large mechanisms in course of erection the fixed tools cannot be brought into use. Apart from the trouble of carrying massive castings to and fro in a shop, there is the question of cost of machines, which, to hold such work, would need very large beds or tables, and arms or rails of great span to reach over and cut upon the various portions. In following such methods, there would also be a lot of re-setting and clamping to ensure the different sections being tooled correctly, which setting would often consume more time than the actual cutting, on account of the awkward shapes, necessitating much packing and blocking up.

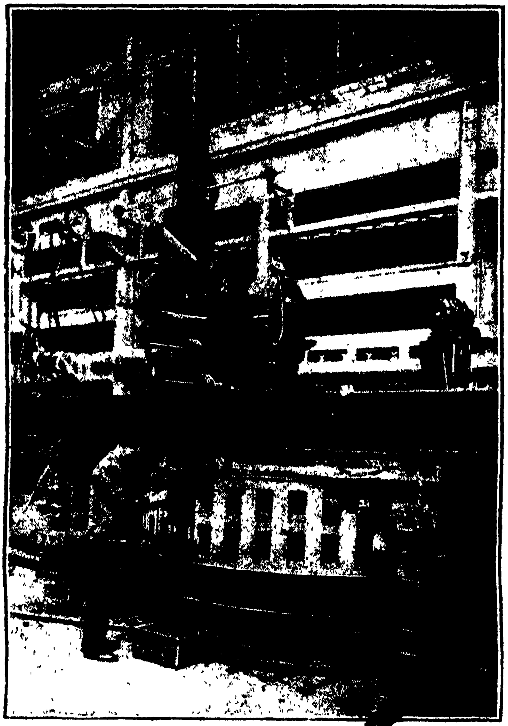
The Uses of Portable Tools. Again, after the erection of an engine or other mechanism has begun, there is frequently a good deal of machining to be done as the work progresses, especially drilling of holes, the locations of which cannot be determined at the beginning. If no portable tools were available, the work would have to be done with hand tools, or the portions dismantled, and taken back to the machine shop, obviously an uneconomical procedure. In those works which are unprovided with suitable portable machines one often sees a good deal of chipping and filing done on the smaller areas, to avoid sending them to the shop, and a large amount of drilling and reamering effected with the ratchet brace, worked by hand. Both of these methods are slow, and not always accurate, so that a demand has grown for special tools that can be taken to the job, and affixed to it in any position, to plane, shape, slot, mill, drill, ream, tap, grind, or polish any sections. These portables are of comparatively small size, and correspondingly cheap by comparison with big fixed machines, with their expensive foundation, and their handiness is such that an operation may be completed in certain instances long before the job could have been taken to a fixed tool, set correctly, and bolted down. It is a case of adjusting the tool to the work, instead of vice versâ. The amount of power consumed in moving the light parts of a portable machine is less than that required by a fixed class of machine of similar capacity, the advantage being due to the difference in mass.

Types of Portable Machines. There are three kinds of portable machines—those placed upon a plate in the shop and moved about around the work, those which are attached direct to the work, and the light ones which are simply held in the hands and presented to the work. The last method is possible only in the lightest classes of operations, and is confined chiefly to drilling and tapping, chipping, caulking, riveting, and grinding. The question of whether the tool shall be attached to the work or to a plate alongside is often one of relative convenience, and may depend on the character of the operations to be performed. If a large casting has to be planed, shaped, or slotted, and then drilled or milled on various faces, it is better to fix it firmly, and shift the tools about into different positions to suit the

97. FLOOR-PLATE

requirements. This is called *floor* or *surface plate* work, and is carried out most extensively in the large electrical factories, building dynamos ranging up to 30 ft. or more in diameter, the segments of which are handled on floor-plates. Engine builders also employ *floor-plates* for tooling some of the massive beds, standards, and flywheels.

Floor-plates. The floor-plate provides a large, flat area, upon which work may be set accurately, and held, while the machines are placed where desired to operate on the different parts. The plate is practically one large foundation or table common to a number of machines, instead of belonging to one only. As the accuracy of the work done depends on the condition of the plate, it is constructed strongly, and set with great care. Cast iron is the material used, and it is built up with a number of sections bolted together to form a sufficiently large area to carry one big piece of work, or several sets on different portions. Figure **97** gives a plan and elevation of a moderate-sized floor-plate (Francis Berry & Sons, Sowerby Bridge), measuring 20 ft. by 14 ft. It is of hollow form, 1 ft. 2 in. in depth, and provided with longitudinal and cross ribs, seen dotted. The plate is built up in two pieces, jointed along the centre with a tongue and groove, and secured with forty bolts. There are 28 longitudinal tee-slots for 1¼-in. bolts by which the work and the portable machines are secured. Gaps are made at three locations, as seen in the plan, to enable bolts to be lowered into the slots and moved along to position, instead of having to start them from the end, and slide them right along. Apart from the time thus saved, it might often happen that a slot would be covered by some portion that would prevent the bolts being slid past. The top of the plate is planed all over, and the edges are also planed to serve as guides to set by. The term *marking-off table* is also applied to this plate, because from its true face surface gauges, squares, etc., may be operated to mark out work by, just as it is done on the smaller marking-off tables in the machine shop. These instruments are also employed to set the castings, etc., truly upon the plate in readiness for the tooling. It is obvious that with a job thus placed upon its plate, and machined by tools also resting on the plate, the results must be as true as though the piece was set on an ordinary planer or slotter or drilling machine.



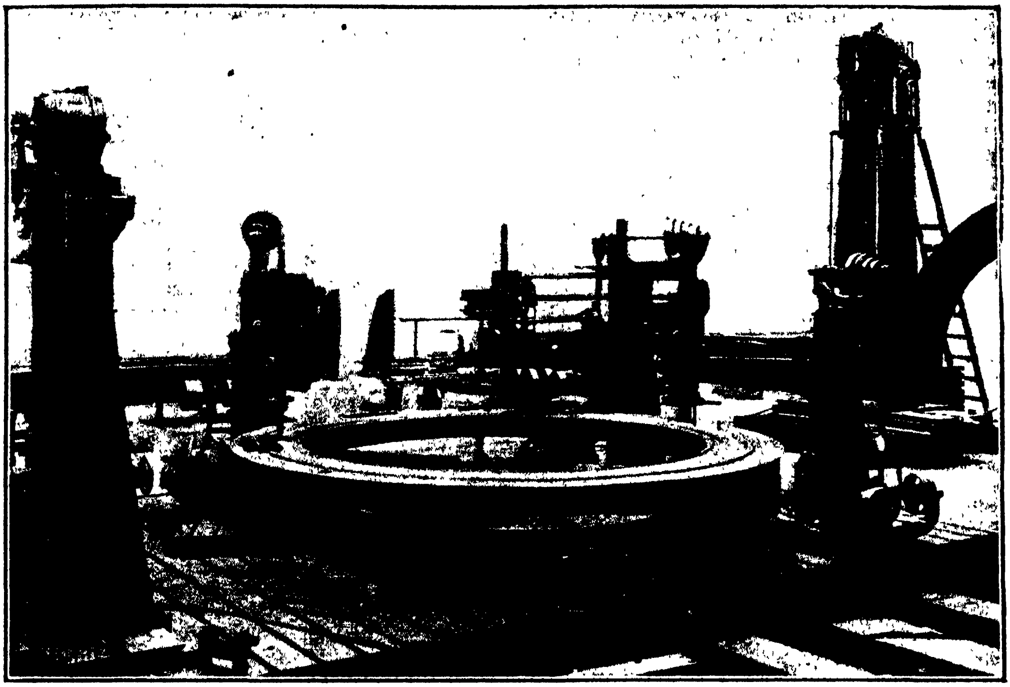
PORTABLE SLOTTER TOOLING WESTINGHOUSE ARMATURE SPIDER

A Large Floor-plate. Plates larger than this example are necessarily built up of a number of pieces fastened together. Probably the largest plate in use is that of the Westinghouse Electric and Manufacturing Co., at Pittsburg, employed for the machining of large generators. It measures 176 ft. long by 48 ft. wide, and is composed of 132 sections, each 8 ft. square, bolted and keyed together. An ample foundation is afforded by brick piers, 12 ft. deep, standing on a bed of concrete, 3 ft. 6 in. thick, the piers being spaced 4 ft. apart, and connected by brick arches. All the space between is filled in, and finished with concrete, the top of which comes about 5 ft. below the underside of the floor-plate. The object of this is to form a chamber into which cuttings may fall through holes in the bottom of the tee-slots, and be removed by doors communicating with the chambers. The latter may be flushed out with water when necessary. Powerful travelling cranes run overhead above the plate, to handle the work and the machines on it. The total weight of the cast iron in the plate is about 1,000 tons.

Between such a plate as this and the one in **97** various sizes are made, according to the requirements of the shop. Even if the work handled is not very large, the plate may have a considerable area, in order that two or more sets of work may be put on it at once. If there are not enough machines to operate on all the pieces simultaneously, the advantage is still gained that setting and bolting down may proceed at one part of the plate in readiness for the tools when they are free to leave other work elsewhere.

Floor-plate Work. The photographs showing views of floor-plates in operation will help the reader to understand the methods of working, and the drawings of the portable machines following indicate the features which are special to these types. Figure **99** gives a general view of a portion of the floor-plate at the works of the British Westinghouse Electric and Manufacturing Co., Ltd., Trafford Park, Manchester. The photograph was taken before one of the sections had been put into place, so that the brick piers are seen at the bottom of the picture. The object being dealt with is a large ring, supported on blocking attached to a revolvable table, and three radial drilling machines are drilling holes around the ring. The latter is revolved at intervals to bring it into fresh positions for other holes, the machines therefore remaining stationary. Figure **98** shows another use for the revolving base-plate, the object being an armature ring, or spider, which is bolted to the plate and given partial rotations to come under the ram of the portable slotter, which is elevated upon packing blocks above the work. As each slot is made in the periphery, the table is turned sufficiently to set it for another slot. The operator is seen testing the setting. If a large circular object like this were done by the fixed machine, it would necessitate the use of an abnormal table on the slotter.

In **100** an operation with a drilling machine inside the work is shown. The machine is of pillar



99. FLOOR-PLATE WITH RADIAL DRILLS AT THE WESTINGHOUSE WORKS

type, with a spindle driven in a bearing that is adjustable up and down within the pillar. The drill is thus moved to any position. In the photo it has already put through one hole in the generator yoke, and is engaged on another above, these holes serving to attach the pole-pieces. By turning the entire machine upon the circular table (mentioned above), it is made to align with the other holes inside the ring.

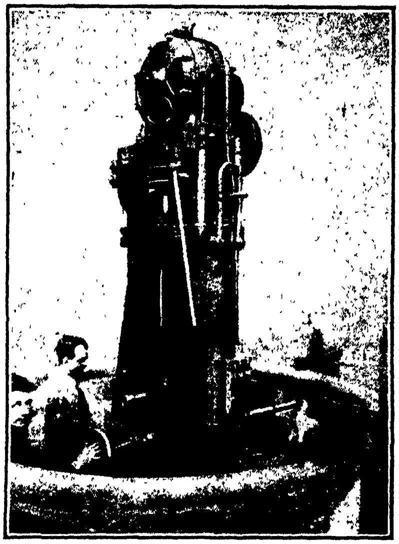
Tooling of another class is illustrated in **101**, the machine being a rotary planer or face-milling machine, of the class described in the last article, with a number of tools pinched in holes in a large revolving disc. The latter is mounted on a spindle running in bearings in a sliding carriage, that moves down the long bed and so makes the milling cutter face off the work, feed for depth of cut being imparted by a transverse slide on the carriage. The work shown in the photo is the bottom half of a steam turbine casing, blocked up with angle plates and screw jacks on the floor-plate, while the bed of the milling machine is clamped with bolts and clips.

A large amount of facing work is done with machines of this class as an alternative to putting the job on a planer or slotter. Joints of flywheels and of dynamo segments are typical examples of awkward pieces which are best treated upon floor-plates, while many kinds of beds and bases are well suited to the method of working. There is also some saving of time by milling, over planing, or slotting, in work of the character shown in **101**, in which a single-pointed tool would have to "cut wind" for a good deal of the time in passing over the gaps.

A considerable amount of packing of various kinds is used on the plates, including plain parallel strips or bars, girder-shaped pieces, and castings with tee slots to carry bolts which clamp work down, as seen in the views **98** and **99**. These are necessary to raise the work off the plate sufficiently to let the cutting tools clear, or to elevate the portable machines into suitable positions. Sometimes also the castings may have projecting lugs or bosses which prevent their being laid on the plate to stand without rocking about; by slipping a packing block under each end the projecting portion is raised clear off the plate.

Floor-plates, like planing-machine tables, usually have their surfaces provided with a number of round holes, into which stop-plugs are inserted to resist the thrust of cutting, and so to relieve the holding-down bolts to a certain extent, and prevent risk of a sudden slip during tooling. The usual clamps and bolts for planer work are employed on plates to hold down the work and the machines. Large numbers of wood blocks and struts are used to support the free ends of clamps which press upon the work, the wood being lighter than iron packings, and nearly as satisfactory for the purpose, although for packing up the castings or the machines, the more rigid and unyielding iron blockings are better. Screw jacks, for adjusting the height of castings, are found on most floor-plates; they are more convenient to use than wedges, affording a steady lift, with great precision of movement. The service of an overhead crane is necessary in the first place to carry the work to the plate and hold it until blocked up, but after that the final small adjustments can be effected by the jacks. Hydraulic jacks are sometimes applied where the weight of the job is excessive.

Setting Work on Floor-plates. The setting of large pieces of work on floor-plates involves the use of special instruments which are not found on ordinary machine tools, including large squares and straightedges, and various gauges. For example, in setting segments of large dynamo rings some means must be found of gauging the radial setting, and of marking out the inside for slotting the facings which hold the pole-pieces. A central pillar is clamped on the plate, and a long radius rod pivoted from it to reach out to the segment, which is fixed down at the correct distance. The truth of the circular setting is then tested by slewing the rod round on its pillar. The setting of the portable slotter or drill is also tried by a rod.



100. PORTABLE PLANER OR SHAPER

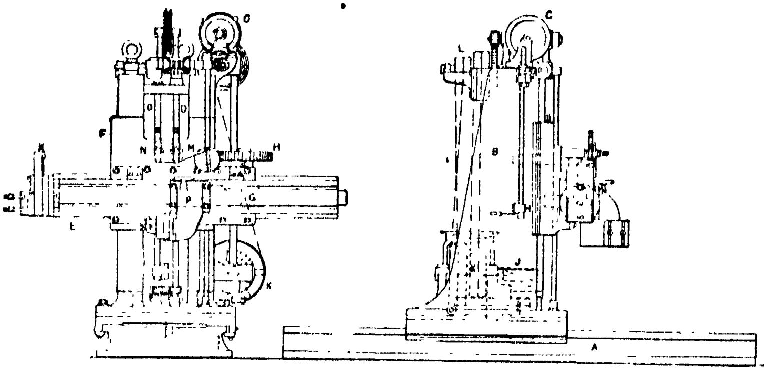
An interesting method of laying out big work has been adopted at the Westinghouse works at Pittsburg. A number of huge generators for the Manhattan Railway Company were ordered, having a total height of 42 ft., the revolving portion being 32 ft. in diameter, and the devices then in use for dealing with work of the kind were deemed inadequate to cope with the abnormal machines to be built. It was feared that errors would creep in as regards the machining of the segment joints and the drilling of the bolt holes, and a novel departure was made by the employment of surveyor's methods, using a dividing and levelling instrument mounted upon a column bolted to the floor-plate. The ring segments were each in turn packed up and clamped at the correct radial distance from the centre pillar, the testing being done by a centring gauge pivoted on the pillar. The correct angles of the joint faces were then determined by sighting with the instrument mounted on the pillar, and straightedges were clamped to the plate in exact radial positions as found by the instrument. The base of the portable slotting machine was then set parallel with a straightedge, adjustments being effected with setting screws, clamped down, and the segment joint tooled across, the slotter being moved subsequently to the opposite end. The bolt holes in the ends were afterwards drilled, using a jig plate to bring them all alike in each segment. After putting together the lower half of the ring, it was tested with the instrument to note whether the joint faces coincided with the centre of rotation, the result being satisfactory. Other tests showed that the machining had been performed very accurately.

101. PORTABLE ROTARY PLANER AT THE WESTINGHOUSE WORKS

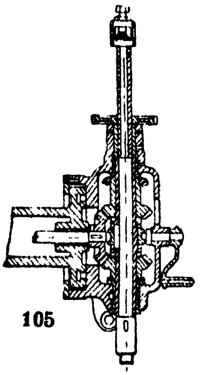
The instrument was employed also in dividing round the periphery of the rotary portion of the generator, to locate the positions of the slots. The operations were carried out on the large floor-plate mentioned previously in this article, and the methods are still followed by the company in dealing with their large floor-plate work.

Floor-plate Machines. Coming now to details of the machines used on these plates, we find that they have certain points in common with ordinary machine tools, as regards slides, spindles, feeding and adjusting devices, but the forms of the framings may differ somewhat, and the methods of driving are not similar, on account of the new conditions to be met. A portable machine must obviously be free to move about to any required position, and it is impossible to encumber it with belts, or tie to it any countershaft positions. Happily the electric motor has solved this difficulty, enabling machines to be shifted about anywhere, and the power to be supplied through flexible cables, which may lay along one of the tee slots or lead off in any direction where it is not in the way. Several cables are visible trailing off the plate in **99**. Previous to the introduction of the electric drive, a moderate amount of driving was done by means of round ropes, rotating vee'd pulleys on the machines, and allowing the latter to assume any angular positions. Ropes are still employed for some classes of work, as we shall see later; but the many advantages of electricity have caused the older system to be largely ousted. The disadvantage of having running ropes about the work is obviated by the motor drive, in which the moving parts are contained entirely on the portable machine, so that it may be placed in very awkward or confined situations without regard to surroundings.

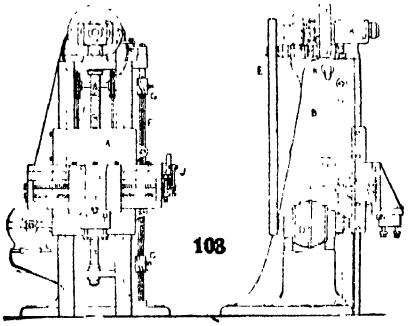
The Portable Planer. The reciprocating machines naturally constitute a large proportion of the types used on plates, and they are well adapted to the planing of joints and faces, including grooves, keyways, and dovetailed slots. Planers or shapers, and slotters are employed, the first-named having horizontal strokes, and the second vertical strokes. An example of a planer or shaper is illustrated in **102** (John Holroyd & Co., Ltd., Milnrow). It is styled a *universal machine,* on account of the complete range of movements possible. The base portion is an 18-ft. bed, A, which is held down on a floor-plate by clamps pressing on the bottom flange. The column B, gibbed to A, slides upon it longitudinally by hand movement with a ratchet lever, or by power, from the 6½-h.p. motor, C, which makes 500 revolutions per minute. There is a spur gear drive from the motor shaft to one immediately below it, whence mitre gears (seen in the left-hand view) drive to a nest of bevel gears on the



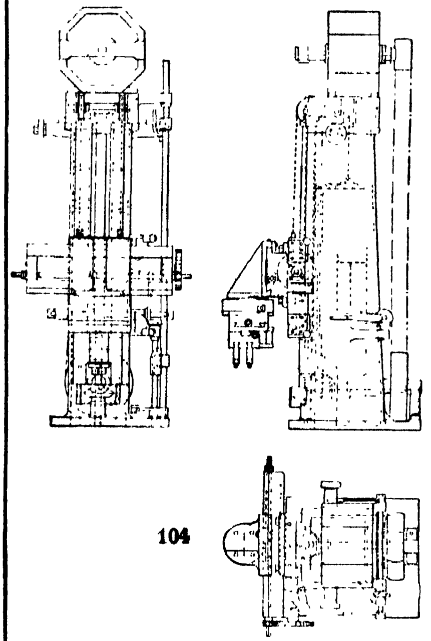
102



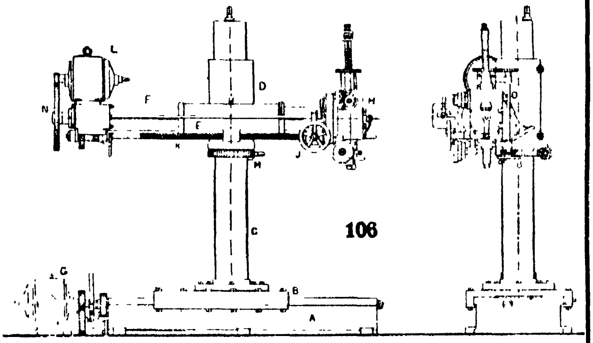
105



103



104

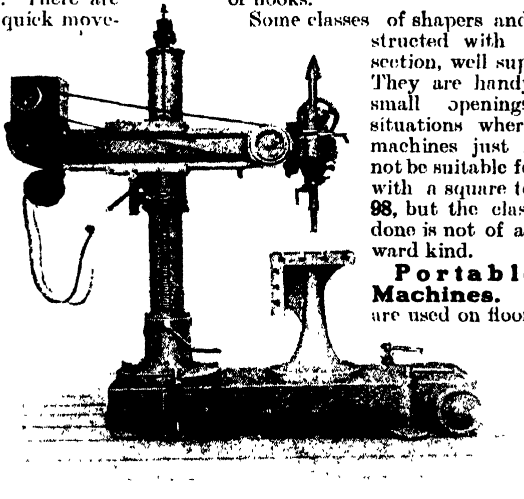


106

102. PORTABLE SHAPER 103–4. PORTABLE SLOTTERS 105–6. PORTABLE DRILLING MACHINES

top of the column, combined with a claw clutch by which the shaft D may be revolved in either direction. D passes down the column and drives a train of spur gears ending in a pinion that engages in a rack fastened to A, so that when the train is set in motion the column slides along. The base of the column is of circular form, fitting on the saddle below, that slides on A, and the edges are indexed so that B may be revolved to any angular position, and clamped by the bolts seen in the left-hand view on the base, this provision enabling the ram to be faced round, to shape work at any angle without troubling to shift the bed, A. The ram slides in a saddle, F, fitted on the front face of the column, and is driven to and fro by a pinion and rack, G, rotated by a spur gear, H, which derives its motion from a pair of bevel gears, J, driven from the sets of fast and loose pulleys, K, operated by other pulleys, L, at the top of the column, also driven from the motor through spur gears. The difference in diameter of the sets of pulleys K and L, affords a slow rate of cutting and a quick return, a device already described in connection with planing machines of standard forms. The belts are shifted by forks actuated from adjustable dogs on the moving ram, E. At each stroke a partial rotation is given to the disc, M, which rocks a lever connected to two ratchet pawl levers, N. These effect partial turns of ratchet wheels, operating mitre gears which transmit their motion either to the shaft, D, or to a screw, O; if the first, the result is that the column, B, is moved along its bed, A, a little after each cut taken by the ram; if the second, the saddle, F, is fed similarly up or down the column, so that the surface of the work is gradually covered either in a vertical or a horizontal plane. The tool-box at the end of the ram may be angled upon a circular facing, to point the tool into corners; a clapper-box fitting is provided for relief. Another box, P, is bolted to the front of the ram to do face planing where the box at the end cannot be conveniently applied. Other points which may be noted in this machine are that the saddle, F, is counterbalanced with a rope passing over the pulley at the top, holding a weight (not shown) inside the column, and that there are a couple of eye bolts let in the top of the column, by which the entire machine, which weighs about 13½ tons, may be hoisted with the overhead traveller and carried to any part of the floor-plate. The stroke of the ram, which is 4 ft., is arranged to return at double the cutting speed.

Portable Slotters. The vertical slotters are employed for tooling work that has deep vertical faces of no great width, the machine [**103**] being made without a long bed. This machine, also by Messrs. J. Holroyd & Co., Ltd., is constructed with a saddle, A, moving upon the face of the column, B, the mass being counterbalanced by a weight inside the column, suspended with two wire ropes. The vertical stroke of 4 ft. 6 in. is obtained from a large, square-threaded screw, C, working in a nut on the back of the saddle. The 5-horse power motor, D, is belted up to a pulley, E, that connects to bevel gears on the top of the screw, through intermediary spur gears (covered with guards). There are two available ratios of slow and quick movement by these gears, thrown in and out by a friction clutch between the top pair. The clutch is actuated through a series of levers worked from the rod, F, carrying two adjustable dogs, GG, which are struck by pins on the moving slide, A, and given a partial twist through the medium of cam grooves on their outsides. At the same time that the twisting of F produces the reversal a feed is given to the tool-box saddle or to the box slide itself by mitre gears driven from F and communicating with a crank disc and ratchet and spur gears situated at J, the effect being similar to that of the mechanism already described in connection with planing machine feeds. The cross motion of H is limited to 2 ft. 6 in. There are two lifting hooks, one of which is indicated at K, and the base of the column has several bolt holes.



107. PORTABLE DRILLING MACHINE MOUNTED ON TROLLEY BASE

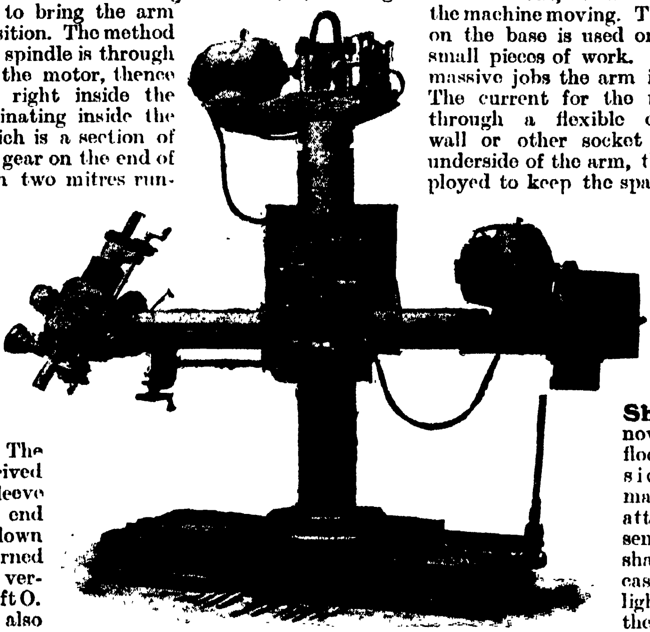
It may be noted that the bottom edges of such machine bases are planed square, in order that they may be used as guides to set the machines by—a simple and ready method which saves much time.

A vertical slotting machine having 4 ft. stroke is shown in **104** (John Hetherington & Sons, Ltd., Manchester). The interesting feature of the design is that the quick return is effected by altering the speed of the motor on the top of the framing, instead of through reversing clutches or other means usually adopted. The motor shaft has a pulley from which a belt goes down to a larger pulley on the base, driving bevel gears, at the front of the frame, which rotates the vertical square-threaded screw that moves the saddle up and down, balancing being done by a weight shaped to suit the inside of the column, and suspended over pulleys by two Renold chains. As the saddle slides, rollers mounted on brackets at the top and bottom corners alternately come into contact with cam-shaped dogs on a vertical shaft just behind the saddle, and twist this shaft, causing it to operate a reversing switch (not shown) that changes the direction of rotation of the motor, and alters its speed. During the cutting stroke of 20 ft. per minute it runs at 350 revolutions per minute, and on the quick return of 40 ft. the rate rises to 700 revolutions per minute. The twisting of the reversing rod also imparts a feed to the cross-slide on the saddle through ratchet and spur gears in a manner that has been mentioned previously. The tool-box, not shown in the front elevation, may be angled upon a circular facing on the underside of the angular bracket sliding along the cross-rail. Provision is incorporated for reversing the motion of the saddle by hand through the handle seen against the column in the side elevation, the movement of this handle operating mitre gears turning a short vertical shaft, which is connected at the bottom, by pivoted levers, to the reversing shaft. The bottom edges of the base are planed true. Some machines of a similar character are raised up on a box base to fit them better for coping with deep work on the floor-plate. There are two lifting snugs standing out from the sides of the column in **104** to afford a hold for the crane slings or hooks.

Some classes of shapers and slotters are constructed with rams of square section, well supported in guides. They are handy for getting into small openings and confined situations where the types of machines just illustrated would not be suitable for use. A machine with a square tool ram is seen in **98**, but the class of work being done is not of a difficult or awkward kind.

Portable Milling Machines. Milling machines are used on floor-plates, the two principal types being those represented in **100** and **101**. Figure **100** is shown at work drilling, but the style of machine is adapted also for milling, and is especially useful for grooves, which it can finish rather more quickly and uniformly accurate than the shaper or slotter. The other type of miller in **101**, used for tooling off large surfaces, is made with differing lengths of bed, according to the service required. The large cutter heads are driven by a pinion engaging with a ring of teeth inside the rim, which gives a better drive than attempting to drive the spindle alone.

Portable Drilling Machines. The drilling machines form a large proportion of the tools used in conjunction with floor-plates. Sometimes those of ordinary radial types are employed, as seen in **99**, but usually the designs are special, with the object of increasing the reach and capabilities of the tools. The favourite form is that embodying a circular pillar supporting a transverse arm, producing thereby universal movements. In the machine shown in **105** and **106**, the bed, A, receives a slide, B, upon which the pillar, C, is bolted. C is embraced by a sleeve, D, cast with a tubular bearing, E, at right angles, within which is the arm, F. The saddle, B, can be moved along the bed by hand, using a ratchet handle on the squared end of a screw lying within the bed, or more rapidly by power, with a motor, G, shown dotted, driving the screw through spur gears. There is also another use for the motor, that of driving a splined shaft alongside the screw, communicating with bevel gears to a vertical screw inside the pillar, C, by means of which the sleeve, D, is adjusted up or down quickly. A hand motion may be alternatively produced by the squared handle-end at the top of the screw, seen projecting up out of the pillar. The drill spindle is carried in a head, H, at one end of the arm, F, and the motor for driving is at the other, thus balancing approximately. The arm may be moved through its bearing by turning the hand-wheel, J, connected to mitre gears, which turn the screw, K, working in a nut in E. A power movement is also obtainable from the motor, L, driving to spur gears communicating with the screw, the connection being made or broken by a clutch. The worm gear at M is used for turning the sleeve, D, around the pillar, to bring the arm into any desired position. The method of driving the drill spindle is through the gears, N, from the motor, thence by a shaft passing right inside the arm, F, and terminating inside the head [see **105**], which is a section of the box, H; a mitre gear on the end of the shaft gears with two mitres running loosely on sleeves encircling the drill spindle, and driving the latter in one direction or the other, according to whether a claw clutch between the mitres is slid up or down by the cranked handle seen outside the head. The spindle feed is derived from a screwed sleeve encircling its upper end and moved up or down by a spur gear turned from a pinion on a vertical hand-wheel shaft O. Self-acting feed is also available, effected by the belt cones seen on the side of the head, the upper one being driven from small bevel gears on the spindle sleeve, and transmitting movement down to the lower belt cone, which drives a worm gear, thrown into or out of action by a friction disc device. The head, H, may be swivelled upon the end of F, and clamped with tee-headed bolts. We therefore see that when the base, A, is bolted down, the drill head may be brought into any position around the circle, either high or low, so that a large number of holes at various locations might be drilled expeditiously. In some designs the long base, A, is not used, the pillar terminating instead as a broad circular foot. The horizontal range of the machine is thereby lessened, though this is of no moment in much work, because it is easy to shift the machine bodily to a fresh position. The advantage of the base is that it enables successive movements to be made, to drill a row of holes all in line with each other.



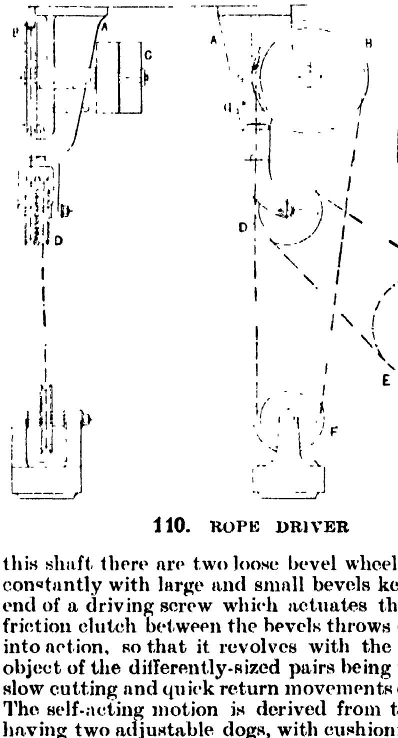
108. ELECTRICALLY-DRIVEN PORTABLE DRILLING MACHINE

Figure **108** illustrates a machine (by Kendall & Gent Ltd., Manchester) of the same general type as that just described. The motor for elevating the arm is placed on the top of the column, and the pillar and saddle are traversed along the bed by screw and ratchet handle. The drilling head, driven by the other motor, is shown set to an angle, and it may also be set round in the other direction by worm gear on the arm. The switches for starting and stopping the motors are mounted centrally on the board at the front.

Before we leave the subject of floor-plate machines an illustration of a combination class of machine may be given, that in **107**. It has a circular pillar, with elevating sleeve, and sliding arm, and the drive is by motor, but the base is different from the examples we have hitherto considered. It is supported on four small trolley wheels, which enable it to be pushed about anywhere without the need of a crane. When set ready for work, the machine is steadied by raising the wheels off the ground by turning four jack-screws, forcing down flat plates, two being seen at the front, so that there is no chance of the machine moving. The slotted table seen on the base is used only for dealing with small pieces of work. When dealing with massive jobs the arm is slewed outwards. The current for the motor is conveyed through a flexible cable led from a wall or other socket to a drum on the underside of the arm, the drum being employed to keep the spare length rolled up neatly. Although this machine may be used for floor-plate work, it is more often employed on the ordinary shop floor, or out of doors.

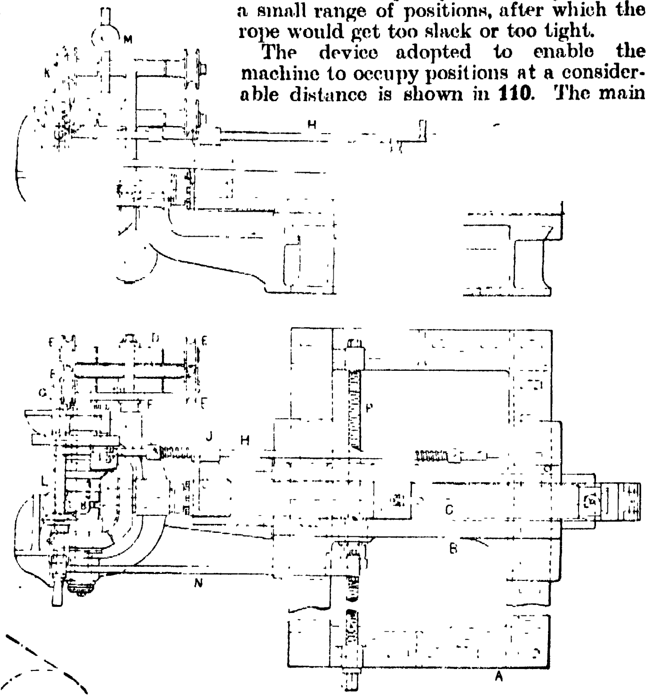
The Portable Shaper. Leaving now the question of floor-plates, and considering portable machines which are attached to, or presented to the work, we shall see that in these cases the tools are of lighter build, since they cannot have a massive foundation plate upon which to rest. The heaviest tools are slotters and shapers or planers of the kind shown in **98**, the long bed being lowered on to a piece of work, such as an engine frame, to enable the bearings to be tooled or various facings machined, instead of endeavouring to do the work in makeshift fashion on machines that are too small for the work. A good deal of key-seating is done with these slotters, especially in the hubs of large wheels, and some kinds of machines designed solely for keyway cutting are used. Figure **109** gives elevation and plan of a portable horizontal slotter or shaper (Francis Berry & Sons, Sowerby Bridge) which is designed for slotting out keyways in the bores of very large flywheels, etc., while they are still in the lathe, after boring. The machine is also applicable to tooling faces on big castings that cannot be conveniently put on an ordinary planing machine. The maximum stroke is 30 in. The base, A, well provided with bolt slots in the bottom flange, supports a saddle, B, by vee'd edges. The ram, C, slides in vee guides in B, and its tool-box, fitted with relieving clapper, has a small vertical feed, given by hand through the medium of a vertical screw, operated by mitre gears from a shaft passing back to the middle of the arm, where the handle is situated so that it will not come foul of the work when tooling deep bores. If the handle was placed direct upon the screw, as in ordinary tool-boxes, the operator would have no chance of reaching it. The tool-box can be turned upside down for keyways on opposite sides.

The machine is rope-driven through a large pulley, D, the rope being kept in its grooves when running at various angles by four grooved guide pulleys, E, E, E, E, lying above. There is a spur pinion on the stud of D, gearing with a wheel, G, on a shaft passing across at right angles to the ram, in bearings supported in a bracket casting bolted to the side of the bed, A. On this shaft there are two loose bevel wheels engaging constantly with large and small bevels keyed on the end of a driving screw which actuates the ram. A friction clutch between the bevels throws either pair into action, so that it revolves with the shaft, the object of the differently-sized pairs being to produce slow cutting and quick return movements of the ram. The self-acting motion is derived from the rod, H, having two adjustable dogs, with cushioning springs which are struck in turn by the faces of the bracket, J, on the moving ram. The rod, H, rocks a lever, K, on a shaft, L, connected by bevel gears, seen in the plan, to the clutch-shipping lever. A rocking weight and lever, M, is connected by spur gears with L to retain the clutch in each of its positions after reversal. An automatic feed for the saddle, B, along its bed, is obtainable through the motion of the shaft, L, reciprocating a rod, N, connected to a lever, O, which by a ratchet and wheel effects partial rotations of the feed screw, P, working in a nut on the lower side of the saddle, B. The screw, P, is extended at one end and squared to receive a crank handle for the purpose of making adjustments.



110. ROPE DRIVER

The rope-driving arrangements are of an interesting character because of the necessity for introducing means of keeping the rope taut at all positions of the machine. It is evident that an ordinary pulley fixed overhead in the roof and connected by a rope to the machine pulley would only work in a small range of positions, after which the rope would get too slack or too tight.



109. PORTABLE SHAPER

The device adopted to enable the machine to occupy positions at a considerable distance is shown in **110**. The main bracket, A, fastened overhead, forms a bearing for the shaft of the rope pulley, B, driven by the fast pulley of the pair of belt pulleys at C, the belt being thrown off when required to the loose one through the shipper lever seen behind the bracket, operated by dependent cords. A pair of smaller pulleys, D, are mounted in a forked bracket that may turn freely in a horizontal direction, by means of its circular stem held in the bottom of the bracket, A, with a nut. This fitting allows the rope to slew round to any angle which the portable machine may demand. E represents the pulley of the shaper, although, of course, in actual work it is separated by a long space from the pulleys, D. A weighted pulley, F, is employed to compensate for the varying distances of E from its drive, the endless cotton rope passing down from B to F, which maintains a constant pull upon it, thence round one of the pulleys, D, from that down to E, back again around the other pulley, D, and so up again to B. Should E approach D, then the weight, F, goes down and absorbs the slack rope; if E goes further away, then F rises and pays out more rope. It is clear that a flat belt could not be made to drive in such a flexible manner as the rope does, and it is applicable only in cases where the position of the shaping machine is fixed within a narrow range, a jockey pulley and weight taking up the limited amount of slack which is developed. As we have already said, the greater convenience of the electric drive has had the effect of largely displacing these belt and rope drives, although for shops and situations where electric power is not available they still hold their own.

Portable Cylinder Boring Machines.

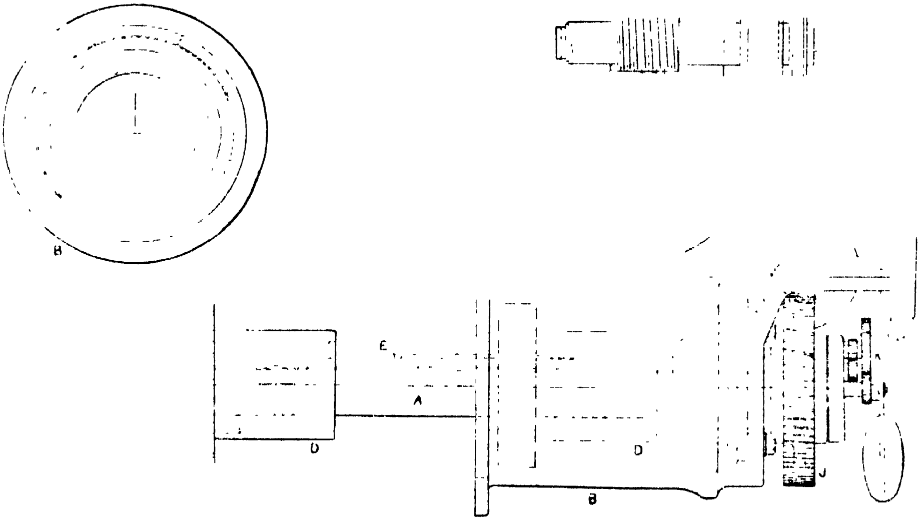
An example of a rope-driven portable cylinder boring machine by James Spencer & Co., Hollinwood, is given in **111**. These classes of machines are not used for original boring, but for reboring locomotive cylinders after they have worn badly. It is often more convenient to be able to true out the bores without troubling to dismantle the engine and carry the cylinders to a fixed machine. The cuts taken are necessarily light, so that the machines do not have to do very hard service. There is no difficulty as regards the attachment of such machines to the cylinders, because the faced ends which take the cylinder covers afford excellent resting-places for the fixed parts of the machines.

In **111** the boring bar, A, is encircled at the driving end by a hollow socket, B, the front face of which bolts to the cylinder end. At the tail end of the bar there is a smaller diameter, that runs in a hole in a stretcher plate (not shown), spanning across the mouth of the cylinder, and bolted to the flange. The two bearings thus afforded keep the bar exactly in the centre of the bore being trued out. The cutters are held in the head, C, by half-round wedges fitting in the semicircular grooves on one side of the cutter slots. Two or three sizes of heads are available, and any one may be used, by screwing it to the face of the sliding sleeve, D. The latter has a nut sunk partly into the upper side of its bore, within which runs a longitudinal feed screw extending the whole length of a groove in the bar, A. The sides of this nut also form a kind of key, by closely fitting the groove in the bar, so that the sleeve, D, is positively driven round as the bar rotates. The socket, B, is made large enough inside to accommodate the boring head, as shown by its dotted outline, so that it may begin to bore from the end. The rotation of the bar is effected through a cotton rope driving the pulley, F, smaller guide pulleys, GG, being located on an arm on each side of F. On the spindle of F there is a worm, H, engaging with a worm wheel, J, keyed to a sleeve on the end of the bar, A. The bearing which carries the worm spindle can be swivelled around on the end face of B, and tightened with tee-headed bolts in a circular slot, so that the rope pulleys may be presented at any angle to the vertical. The automatic feed of the boring head along its bar is produced by differential gears, seen at the driving end of the bar. The first one is mounted loosely on a stud screwed into the bar, and is connected to a lever having a heavy elliptical weight suspended from it, the effect of which, hanging down, is to keep the spur gear stationary, as though it were gripped by some outside clamping device.

This stationary gear has 24 teeth; as the bar revolves, a larger gear of 60 teeth, K, circles around it, and, by the difference in the numbers of teeth, receives a slow revolution on its own axis which is transmitted to a 27-tooth pinion on the tail of the screw E, through an intermediate gear of 18 teeth. While the bar is revolving, therefore, the screw F is turning and feeding the sleeve, D, with its cutter head, C, along very slowly, so that it gradually passes through the cylinder bore. The bar in this machine is 5 in. diameter, and its length is 70½ in. The largest cutter head is 13½ in. diameter.

These useful machines are also constructed to drive by other methods than rope. Hand driving is very frequently adopted where there is no power of any sort available, the place of the rope pulley on the worm shaft being occupied by a flywheel with handle. An electric motor is employed in some machines, driving through spur gears to the worm.

Crankpin Turning Machine. A special machine used also for locomotive work is that for turning up crankpins while in place. The principal element is a right-angled bracket, the foot of which is clamped to the spokes of the wheel. A bearing lying in line with the crankpin carries a shaft with a point centre entering into the countersink in the crankpin end, and a large spur wheel on this shaft is driven by a pinion and handle, or rope wheel. A slide is fastened to project over the pin, and if a tool is clamped in the holder it will travel around the pin and turn it, longitudinal feed being obtained from the end motion of the tool-holder slide.



111. PORTABLE CYLINDER BORING MACHINE

Following on page 5155

LAND AND ESTATE AGENTS

Entering an Office. Qualifications and Premium. Examinations. Starting in Business. The Agent and his Staff

By F. H. WORLEY

IT is our intention in the following columns to discriminate between the two branches of the profession, pointing out the necessary qualifications or special knowledge required for the duties of each, and weighing their advantages and differences.

Qualifications. There are certain natural qualifications which are especially desirable for an estate and land agent to possess. He is placed in the position between landlord and tenant, or proposed purchaser—a situation demanding the exercise of considerable tact—in order that he may bring business to a termination satisfactory to both parties. His demeanour towards the tenants must be courteous but firm, and this demands good judgment as to the exercise of severity or leniency; he must also be observing, persevering, and enterprising.

To the casual observer, the land and estate agent are one and the same, and it is only on more closely examining the details required for the proper performance of the work of each that the division under two headings becomes apparent. To those whose ambitions turn in one of these directions there are matters which must, to a large extent, be considered as personal, such as capital at disposal, and possibilities of working up a connection. In starting a town (estate) agency, for instance, these are comparatively of minor interest owing to the growth of districts and properties continually changing hands, whilst in a country (land) agency there are the important considerations of personal influence (without which it is almost useless to consider this as a career), the necessity for an intimate knowledge of rural life, with either the prospect of an appointment to an agency or agencies, or a partnership.

The Agent's Duties. An estate agent is called upon to deal with a large variety of matters, from the handling of small weekly property, let, perhaps, at a few shillings per week, to mansions and business premises, etc., at considerable rentals. He must, therefore, be able to determine the full annual value of the same, and be a good negotiator so that he may let them to the best advantage. He must be able to undertake the collection of the rents when let, and the supervision of repairs, for which a general knowledge of building construction is advisable. He should also have a fair knowledge of the law referring to property, so that he is in a position to satisfy his clients that by placing their property in his hands their interests are best served, and money and time economised.

The advantages of an outdoor life and its social opportunities are undoubted, but against these must be set the greater variety of detail with which a country agent should be acquainted, and the necessity for an intimate knowledge of the properties in the district in which he is interested, the nature of the soil, crops, etc. He should also have a considerable acquaintance with the tenants, tact in dealing with the matters of rent collection and management, and a general knowledge of the laws and customs affecting landlord and tenant as applied to the country—the Agricultural Holdings Act, etc.

The Allied Professions. Professions frequently allied to that of the estate and land agent are those of the surveyor and valuer, and often of the auctioneer. As regards the surveyor, it is obvious that the continual handling of plans and specifications form part of his ordinary duties; and alterations or differences which may arise are matters which are best dealt with by a specific knowledge of their requirements. As a valuer, it is more than probable that the estate agent's intimate acquaintance with the property in which he deals places him in the best position to supply the necessary information; and to enable him to legally charge for his expert opinion it is only necessary for him to take out a licence at an annual cost of two guineas. For the same reason, the duties of an auctioneer can be well filled by him, and the fees and commissions accruing from sales may add to his income a not inconsiderable amount which would otherwise be diverted into other sources, frequently with less satisfaction to the vendor and purchaser. At the same time the transaction of such business will probably add to his connection [see also AUCTIONEERING].

It must, however, be borne in mind that a ready flow of language and quick repartee are necessary assets in this profession, an auctioneer being frequently called upon to exercise skill in his powers of description and persuasion, and in grappling with any awkward questions that may arise. An auctioneer's licence costs £10 annually.

Having briefly distinguished between the branches of the profession as followed in town and country we must further investigate the necessary training required for a successful career in either direction. We have seen how, to a large extent, the immediate environment, or at least the early years spent in a city or provincial life, will have considerable bearing on the ultimate success. It is easily seen that a youth whose daily surroundings are not limited or confined to streets and buildings, and whose conversation, habits, and acquaintances are naturally more or less imbued with the common interests of the country-side, will have an instinctive grasp of subjects that could be only superficially acquired by a town-bred student after laborious book research. In short, there would be all the difference between a practical and a purely theoretical knowledge. On the other hand, in a city life the eye is familiarised with a far greater variety of buildings; structural operations are constantly in progress, and there is the more immediate contact with all branches of commerce—an all-important factor in the preparation of an estate agent's education

ESTATE AGENCY

Taking an estate agency first in order, we will enumerate the various steps necessary for a youth leaving school to enter the profession, presuming that he is in possession of a fair, elementary, commercial education. The first matter of importance is the selection of a suitable office where the routine may be thoroughly mastered in all its branches. Hence we do not advise entering a very large office at first, as it is probable that in the comparatively brief period of the youth's indentures too much time would be occupied in departmental work, to the exclusion of a more general experience.

The Agreement. The all important selection having been made (taking into consideration the question of premium), it is customary, in the interests of both parties, that at least a month's trial should be given, so that the proposed pupil may have an opportunity of definitely deciding whether the career will be to his taste, and that the principal may have an opportunity of determining the proposed pupil's suitability. On both sides important decisions have to be made before a binding contract is entered into. The term of probation having expired, by mutual consent a deed of indenture is drawn up, whereby the parties enter into an agreement commonly known as *Articles.* This document generally embodies most of the old apprenticeship clauses, especially as regards obedience and punctuality, and stipulates that the pupil shall further the interests of the master to the best of his ability, etc. It is usually entered into for a term of three years; it specifies the agreed amount of premium, and further sets forth that it is entered into by the pupil of his own free will and accord, and, if he is under age, by the consent and approbation of the father or guardian. It mentions the profession or professions he is to learn, the period the indentures are to last: that he shall faithfully serve his master, keep his secrets, and obey his commands; not absent himself unlawfully, and shall in every way act as a faithful apprentice. On the other hand, the master agrees "to teach, or cause to be taught, and instructed by the best means in his power," the art, trade or business of an estate agent, etc., etc.

The Premium. The amount of premium is a matter for negotiation; as a basis, however, we should say £50 would secure entry in a suitable office for a term of three years. This sum may be increased and a portion returned as salary during the latter period of the apprenticeship.

It is not advisable to enter an office where there are many articled pupils. In fact, if there are no others it is greatly to the advantage of the one, as his duties will secure a much more varied insight into office routine. This will include the usual elementary matters, such as indexing, letter-filing, etc., followed by making tracings of plans, copying specifications and inventories. The pupil will be required to accompany his principal when surveys and valuations are being made.

By exercising intelligence and noting the particulars gathered and the reason for their notification, he will accumulate a store of useful knowledge which he will be called upon later to employ without supervision. During this time he should be continually on the alert, watching the procedure of the office business in every direction, so as to be conversant with matters of difficulty and doubt. He will find that the opportunity the letter books present for studying correspondence will be of great assistance, not only as to the replies themselves, but their formula, phraseology, etc.

Concurrently with such daily practice it is advisable, where possible, to arrange that the spare time which may be found at his disposal shall be utilised in reading for some of the examinations. Those of the Surveyor's Institute naturally take precedence, and of these, the Students' Examination, held annually in January, is the one for which we advise early preparation. [See Schedule, page 160.]

Examinations. It is usual to take this examination at about the age of 18 years, and the subjects embraced belong to the ordinary school curriculum. If, however, the student can produce a certificate showing that he has passed the Matriculation Examination of the University of Oxford, of Cambridge, of London, or of any other University in the United Kingdom: or that he has passed with Honours the Senior Local Examination of the University of Oxford or of Cambridge; or has obtained a Higher Certificate at the examination of the Oxford and Cambridge Schools Examination Board, he will be exempt from this preliminary. Entrance to this, however, is only allowed on proof (1) that the student is, or has been, a pupil of a surveyor; (2) that he is training with a view to entering the profession at one of the recognised agricultural colleges.

After he has been duly elected as a student, the next step that he should take is the qualifying Examination for the Class of Professional Associateship; and in this case the age at which he may sit must not be less than 21½ years. Of the three heads into which this examination is divided, one subdivision applies entirely to the estate (town) agent, and includes these subjects:

(1) Land Surveying and Levelling. Elements of Trigonometry.
(2) Bookkeeping.
(3) Law of Landlord and Tenant (Elements of).
(4) Enfranchisement of Copyholds.
(5) Mensuration.
(6) Law of Fixtures.
(7) Law of Dilapidations.
(8) Law of Easements and Riparian Rights.
(9) Application and use of Valuation Tables.
(10) Drainage and Sanitation.

In addition to the list of subjects given above, the student is required to prepare a plan to a given scale of a property of about twenty acres, showing a section of the levels, and taking the chief angles with a theodolite.

It may here be mentioned that it is not compulsory to become a student before entering for the Professional Associateship Examination, but a non-student will be required to gain a larger percentage of marks than if he had passed the preliminary examination.

The third stage is reached in the Fellowship, the subjects of which are practically those of the Associateship, but in a more advanced degree.

Copies of the revised syllabus of subjects, list of textbooks, and examples of papers set at preliminary and professional examinations can be obtained on application to the Secretary of the Surveyors' Institution, 12, Great George Street, Westminster, S.W., at the price of 1s. 6d. per copy.

As a considerable portion of an estate agent's time is expended on the details of properties placed under his charge, it is essential that a good practical knowledge of bookkeeping should be his particular care. He should be business-like not only as regards his own engagements, and so on, but in thoroughly recording the various transactions which may pass through his hands.

Estate Management. Estate management includes the collection of rents, the supervision of repairs, and, in fact, generally acting in the interests of the owner of the property, seeing that tenants' covenants are strictly adhered to, so that the reversion is not jeopardised.

The keeping of office registers of properties must be systematic, so that the smallest detail can be referred to without delay. Making and checking inventories require a good knowledge of technical terms in addition to a keen insight into present market values. Preparing schedules of dilapidations and wants of reparation also falls under the duties of an agent. Their settlement is a subject for negotiation between the freeholder and leaseholder, or between the original leaseholder and tenant.

It naturally involves a strict attention to the interests of whichever party the agent may be representing.

In taking particulars of properties for auction or registering purposes, it will not be sufficient to merely record the obvious facts: whoever draws up the particulars should have the faculty of showing to the best advantage any special feature which he may discern. He will not omit to enlarge on the advantages of aspect, soil, drainage, healthy situation, access, any local places of interest, and the attractions of the neighbourhood generally. In negotiating the sale or letting of properties a business-like agent will avail himself of all correspondence or applications that may have bearing on the particular subject in hand. He will exert all his influence to discover a purchaser or tenant, and not rely solely on haphazard inquiries. He will quickly find that success in this direction will act as the best advertisement for his agency.

LAND AGENCY

Following our assumption that the youth leaving school or college carries with him a fair commercial knowledge, we propose marking out his further studies with the profession of a land agent in view. Undoubtedly, the best connecting link between the general education acquired at school and the practical experience of an estate agent's office will be found in a short course at one of the recognised agricultural colleges, where technical knowledge and theory are acquired together. Here he will have opportunities of learning, by actual work under trained supervision, matters of essential importance both as regards the surface of the land, its chemistry and treatment, and the legal aspect of its holdings. He will thus be prepared to grasp intelligently the more complicated difficulties that may arise in daily practice during the period about to be spent in some estate agent's office.

The general routine of study adopted at the colleges naturally prepares the student for the examinations he will read and ultimately enter for. A general outline of the subjects will be enumerated later. The term of study varies in length, and is to a large extent determined by the amount of money at the disposal of the pupil, his parents or guardians; but we do not advise too lengthened a period, taking into consideration the subsequent years of pupilage to a land agent.

Training. Two years' training in this way should be sufficient. It is not our intention to imply that the preliminary training that we have outlined is essential to an estate agent, provided that such, or similar knowledge, could be gained from another source. For instance, it would be possible to learn the greater part of what is necessary on a well-managed farm where discipline was maintained, and where the student conscientiously made it his business to learn what was going on around him, if at the same time he added to an intimate insight into farming matters by judicious reading of works bearing on the legal aspect of his prospective career. So long as this knowledge is gained, it matters little what is its source.

This preparatory tuition having been obtained, the next step is the selection of a suitable office where the pupil may be indentured. It is advisable, where possible, that an agent should be chosen who has the management of estates in more than one county, as there is thus a more varied knowledge gained as regards the properties themselves, the requirements of their soils, their crops, or stock, and differences in local customs. The subject of the Articles themselves vary but little from those we have already noticed with regard to estate agency, but the period which they should cover may be altered to suit special requirements or circumstances. Taking into consideration the greater extent of the subjects with which the fully qualified agent must be conversant, it is natural that a longer time is covered either in the office itself, or in conjunction with the time spent at an agricultural college, or on a farm. For example, should two years have been devoted to this preliminary training, another two may be sufficient for a pupil's articles. If the training mentioned has been omitted, then quite three or four years will be necessary, and it therefore follows that the expense will be considerably greater in the case of a land agency pupil than with one who merely has an estate agency future in prospect.

As there are so many matters dependent on the individual arrangements of both pupil and master, it is difficult to give any definite idea as to the approximate amount of premium. It is largely a matter to be settled privately, but £100 per annum may be taken as a fair basis.

Examinations. The preparation for examination should occupy as great a portion as possible of the study of an estate agent. In the section dealing with town agency we have noted the advantages of as much spare time as office duties may permit being devoted to reading, and thus supplementing private study. Our remarks equally apply in this case. In fact, circumstances will, in all probability, give more latitude in this direction; but against this disadvantage must be set the inconvenience arising from the possible necessity for travelling considerable distances to attend lectures. The examinations we advise the would-be land agent to prepare for are those entered for by the estate agency candidates—viz., those of the Surveyor's Institute, and, as far as the Students' Examination is concerned, the same remarks apply. In the Intermediate or Professional Associateship, and Fellowship Examinations, a special subdivision is set apart dealing with subjects with which a land agent should be thoroughly conversant. The subjects included are these:

(1) Land Surveying and Levelling.
(2) Geology and Composition of Soils.
(3) Law of Landlord and Tenant.
(4) Agriculture.
(5) Land Drainage.
(6) Bookkeeping.
(7) Construction and arrangement of Farm Homesteads.
(8) Agricultural Chemistry.
(9) Trigonometry.

Special Knowledge Required. It is only possible to acquire thorough mastery of the requirements of a land agent's profession by a knowledge of the comparative methods of agriculture as applied to different countries: for it is obvious that there is a wide distinction between farming and farming pursuits as carried on in the Midlands and that in the northern and southern counties. The agent should know the differences demanded in the treatment of the soil, taking into consideration its productive qualities, whether applied to stock, crops, or minerals. For example, the special knowledge applicable to a district producing fruit would be comparatively useless in a mining district; and a county, the soil of which is chiefly given up to grazing, would naturally require relatively little knowledge with regard to to crops, but considerable experience in the handling of stock. And this experience should include not only the land itself but the buildings erected thereon for the purpose of housing or distributing the distinctive products. For guarding the interests of his superior, the agent will find this essential, not only in the original leasing of land but in its after working or cultivation.

Having suggested the various directions in which his knowledge must be applied, and the manner in which it is determined by locality, it would be well, before leaving the subject, to glance at the general routine work as applied, more or less, to every estate office. Owing to the peculiar, and very often complicated, circumstances under which the properties are held, it will be at once seen that bookkeeping must play a more than ordinary part. Not only must records be kept of everything appertaining to the rent roll, but also of the considerable annual expenditure on repairs and improvements generally. Combined with these will be the ordinary everyday expenses, etc., in connection with any farms which he may have in hand, untenanted for the time being, but which must necessarily be kept in working order. It thus follows that his capacities as a farmer will be severely tested; and as questions such as the amount of compensation to be paid to an outgoing tenant for improvements, etc., under the various Agricultural Holdings Acts enter considerably into rental values, skill as a valuer is an essential qualification.

The Estate Agent and His Staff. Presuming that the preliminary training has been passed, and a profitable use made of the opportunities afforded by office work, we are now in a position to consider what should be done in starting business as a principal or acting partner. As we have already stated, the capital at disposal must necessarily exercise a considerable influence in this matter, as it is obviously less expensive in the long run to purchase a small partnership in a sound concern than to risk the disappointment and financial loss entailed in opening an office which may not, for reasons possibly outside personal control, be a success. Consideration must be taken of the fact that during the first months it is all uphill work, and that a man must be prepared to face the inevitable expenses without any compensating return. He must be prepared to take up the affairs of clients by means of assistants, to whom he will naturally have to pay salaries, and this in addition to rent, rates and taxes of the premises he occupies. Of course, if he is fortunate enough already to have an assured connection, these liabilities will be, to a large degree, lessened, and he may be thereby able to start his venture on a sound basis, adding to his staff as his clients increase. A good rent roll is the backbone of any business, and should be especially sought after and cultivated; for, owing to its reliability, it carries with it a certain assured income.

The least assistance possible is a clerk, with sufficient knowledge of the profession and business capabilities to take charge in his principal's absence, and a youth to fill in the minor office duties. In selecting the former, the choice should fall on a man willing and able to make himself generally useful in all departments, who is also a good canvasser—in short, one in whom confidence could be placed. As the agent's business develops, and the necessity for an increased staff arises, he will find it advisable to engage a junior, competent to relieve the senior clerk of most of the out-door duties, such as those of rent collecting, minor inventories, and canvassing, leaving the former with more time to devote to the necessary correspondence, interviewing, and negotiations. For this position, it is quite possible that he may find what may be termed an "improver"—that is, one who is endeavouring to enlarge his experience after having served his articles elsewhere. At this stage, also, he may have a sufficiently large practice to justify his taking an articled pupil.

Setting up in Business. The capital necessary to start business on one's own account will, to a large extent, depend on the locality selected, and the personal expenses of the agent. If he proposes to begin as an estate agent in town, the sum of £200 or £300 should be sufficient to cover the first year's expenses. As he has the advantage of being able to advertise—a privilege denied nearly all other professions—he has the means of procuring the introduction of business which, by perseverance and application, should steadily increase.

The land agent, on the other hand, must be able to dispose of a larger capital at first, as he, unlike the town agent, has not the facilities for advertising, and to a large extent must rely on business being brought to him. Although the results, when they do come, are better, one frequently has to wait a long time for them. We should, therefore, not advise any smaller sum than £500 in reserve for starting in this way.

The duties of the land agent are so much more personal in their nature than the estate agent's that more depends on his individual efforts, and, there being less of what may be termed clerical work involved, the office requirements are smaller. Here, again, the number of assistants will be determined by the extent of the estates under his control, their area, and the distance separating them. With a comparatively small radius, he will be able to exercise his duties fully without calling in professional aid; but where distance will prevent his giving equal attention in all directions, a sub-agent is generally engaged who is qualified to deal with minor matters as they may arise, referring to the principal agent where important decisions have to be made. The appointment of this official may rest with the agent himself, or he may be engaged by the landlord direct. In either case, although he is the agent's subordinate, he will usually receive his stipend from the owner of the property.

In the control of a farm a bailiff is usually employed. His duties may be likened to those of a foreman, his knowledge being purely practical, and his work confined to the particular farm upon which he is engaged. He sees that all operations on this farm are properly carried out; he is referred to as required, and gives instructions to the various farm "hands" as to what is necessary. He reports in detail to the agent, and receives from him whatever orders have to be given.

Foresters. On most estates of any considerable extent at least a portion of the property will be composed of woodlands, requiring the expert attention of a branch of skilled labourers, known as foresters, whose duties are periodically to prune and otherwise cultivate trees and undergrowths for timber purposes, or as game preserves.

We see, therefore, the reason for the estate agent being acquainted with this subject—so that he may properly direct and supervise work of this description. It is a matter of importance to know exactly how, and at what time, such work should be done that the best results may be obtained, and an eye given to the prospects of the future.

HOW TWINE & ROPE ARE MADE

Winding, Twisting, Cabling, Laying, Dressing, and Balling Twines. Rope Spinning and Finishing

By W. S. MURPHY

THOUGH we have studied the making of yarns for twines and ropes, such as flax, hemp, and jute, there are some kinds of yarns used by the twine and rope manufacturer which he must accept from other workers. The variety of material out of which cords and cables may be made is very wide, including cotton, silks, wool, mohair, horsehair, many kinds of vegetable fibres not yet otherwise recognised as textile, and iron, steel, brass, copper, and many other materials mostly wastes from other industries. As a rule, the rope and twine manufacturer spins his own flax and hemp yarns, accepting from other makers, or spinners, whatever other yarns he requires. At this point, therefore, we begin with the processes in which we utilise yarns, both those spun on the premises and those brought in from outside.

Winding. Some manufacturers buy in their yarns—and all must take those yarns which are not in the direct line of their work, such as cottons, wools, silks, and artificial fibres—from the outside. Those yarns come in hanks, and require to be wound on bobbins. Any common winding reel will serve this purpose, and we should hardly have thought of paying any attention to this detail but for the fact that associated with this operation we have a very useful machine and an operation which is of much service for the higher kinds of yarns. The machine is called a *doubling winder.* There are several forms of this machine in use; but in general the form is a double frame, with the hank wheel, or the bobbin creel and guide on one side, and on the other side the receiving bobbins and guides with stop motion. Possessed of this form of machine, the twine or cord maker can deal with any kind of yarn in any form.

Twisting. Though the yarns may have been doubled, they are yet without that twist which gives them cohesion. Being very simple, and similar in principle to many other textile machines, the twine manufacturer has a large choice in this class of machines. But the whole range can be divided into two classes—one called the *upward twister*, and the other the *tube twister*, or any other kind of common textile twisting machine.

Upward Twister. In spinning, the feed bobbins stand on a creel at the head of the frame, and the receiving bobbins sit on the rails in the middle of the structure. In this machine the positions are reversed. Flyers with three legs work on the spindles which hold the supply bobbins, coming up from the lower end of the bobbin. Midway is a carrier rail for the yarn; above it two grooved cone pulleys; and on the top the creel of receiving bobbins. As the yarn comes off the bobbin, it is passed round the legs of the flyer, up over the carrier rail, round the two cone pulleys, and on to the bobbin. A special feature is the action of the two pulleys. When a fibre is twisted it tends to shorten and curl up. The second cone pulley being wider than the first, and receiving exactly the same amount of yarn, pulls the cord tight, confirming the twist and straightening out the line.

Tube Twister. As the name implies, the special feature of this machine is its twisting tube. In other respects it differs little, if anything, from the ordinary frames used in the spinning factories. By the gentle and efficient action of the tube this frame has been found very useful by twisters of

235. M'CORMICK TWINE-BALLING MACHINE

236. TWINE DRESSING (Belfast Rope Co.)

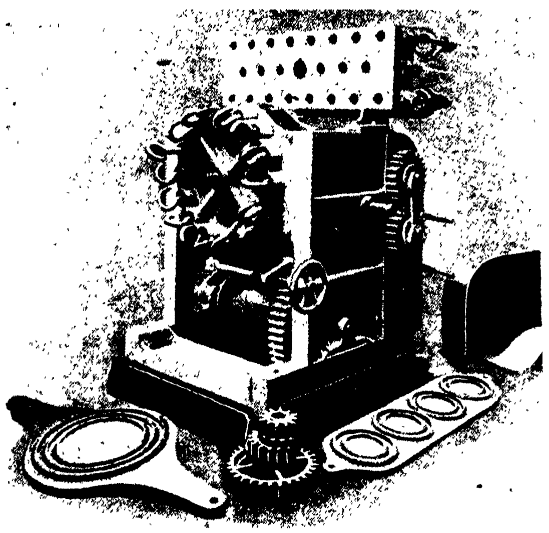
silks and fine cords of all kinds. Sewing machinery, which has become so important in the shoemaking, saddlery, and other leather-working trades, has created a strong demand for the twist made by this machine. It produces a smooth and compact thread.

Cabling Twines. The common twine of commerce is the three-cord cable twine. An extraordinary twisting frame of large size is very often used for this purpose; but the produce is soft and of a low class as a rule. We do not say that a modification of the twister cannot produce good twine; but we think that machines specially designed for the purpose are more likely to prove satisfactory. Among the many to select from we take two, one being quite a departure from the twisting frame, and the other an adaptation of the upward twister.

A Double Cabling Frame. This frame is simply the upward twisting frame with the addition of a cabling side. On this side the three rows of bobbins are placed, with flyers coming up from the base of the bobbins. Above are the two cone pulleys and a guide rail. But in the centre of the double-sided frame are two guides and a collecting tube, while at the other side we find another pair of cone pulleys, and down on the side of the frame a large bobbin upon the spindle of which works a powerful flyer. Coming from the three bobbins, the yarns, or strands, are twisted, led through the small and large cone, and therefore stretched, joined together on the head of the frame, twisted through the pair of cone pulleys on the other side, taken through the head of the powerful flyer, and wound on to the large bobbin. Fishing lines, loom cords, spindle bandings, and high-class twines of all kinds are efficiently formed on this frame.

Laying Machine. For directness of action, the "Patent Laying Machine," as it is named, is certainly very good. From a plate across the head the spindles, containing the bobbins hung horizontally, depend, the bobbins being driven by bands on spindle whorls. Directly under are the guides and twisting gear, while below all rest the receiving bobbins, on the spindles of which revolve large flyers. Twines can be twisted with great rapidity on this machine. Any thickness, from two to six cord, is dealt with, and bobbins of large diameter filled.

Dressing. After the twines have been twisted, the finer qualities of hemp and flax cords are gassed, or singed, by any of the gassing appliances examined in the finishing processes of threads and cloths. Then the twines are dressed—that is, passed through a bath of size—and polished. Some manufacturers omit this process. We think it wise to dress twines, however, not only because the dressing helps to give the strands a closer tenacity, but also for the sake of appearance, which counts for so much in commerce in these days. The size is a thin paste, made of flour, glue, alum, and tallow, in the proportions which experience shows may best suit the particular quality of twine being made. In general, heavy twines are the better of a fair proportion of tallow and alum; for finer twines the alum may be omitted. The dressing and polishing machine [236] is a large piece of mechanism. At one end are the creels, which hold the bobbins of twine; next is the guiding reed, or raddle; next is the steam-heated trough containing



237. FOREBOARD, REGISTER PLATES AND CHANGE WHEELS (Combe, Barbour & Co., Belfast)

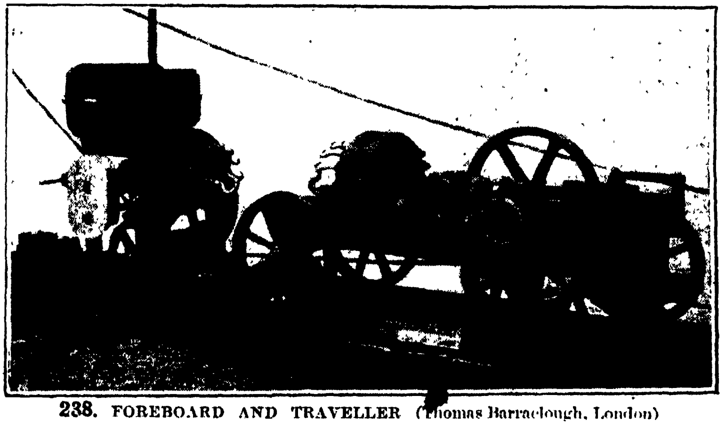
the size; within the trough revolve the dipping rollers; at the further end of the trough, the clearing rollers, a little above, the first brush rollers; next, the drying cylinders; last, the polishing rollers. The twines pass through the guide down into the size, over the one roller and up on the other; here they pass through the clearing rollers, which sluice off the superfluous size, and go through the brush rollers, which partially dry them. Winding helically round the steam-heated drying rollers, the cords pass between the polishing rollers, and are again wound on to bobbins.

Balling and Spooling. Twine is either made up into balls without any core, or wound into a kind of cheese shape, which may have a wooden core or none. Several very ingenious machines have been invented for both these purposes. The cheese winders are merely larger models of the frames used in thread manufacture, studied fully in that section of our course. We therefore omit them at present. The balling machine, however, is new. Two kinds are worthy of special note, and we shall take them in succession.

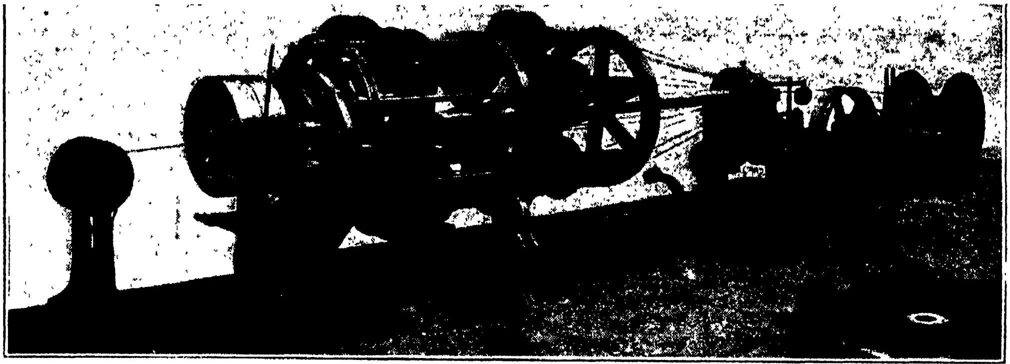
Flyer Balling Machine. The bobbin is fixed on a spindle at one side; in a plate or standard, the flyer is set to revolve in a reciprocating manner over a spindle coming out from a wheel axle on the other side. The twine is given off from the bobbin, and is taken by the flyers and wound on the thick spindle. There are usually two pairs of balls wound on this frame.

M'Cormick's Machine. This machine [235] is generally admitted to be one of the best automatic balling apparatus in the trade. All the parts are very strong. The feed bobbin is hung horizontally on the head of the machine, and the twine is led through the eye of a lever with an eccentric motion, which winds the twine on to the balling spindle set before it. A guide arm keeps the ball firm and regulates the shaping and consistency of the ball. When the required quantity has been wound, the machine stops.

Theory of Rope Spinning. On page 1028 we gave only a hint of the principle upon which rope-making is based. The long, heavy fibres of which most ropes are made do not naturally cling together in a spiral form; on the contrary, they resist being put into that form. It is because the fibres resist twining that ropes cohere. This contradiction, or paradox, must be made clear, and can best be shown by a practical illustration. Suppose we undertake to make a cable about 6 in. thick. First, we take 30 yarns which have been twisted from left to right, and twist them together into a strand by a right to left twist: the effort of the individual yarns to untwist will pull from right to left, and cause them to grip more tightly together in the twist the stranding has given them. Every effort those little fibres make to free themselves from each other binds them more tightly in the larger unity. Nine of those strands have been made, and we now reduce their number to three by combining three strands together. Again we twist from left to right, and the effort of the smaller strands to untwist being in the same direction, they confirm the grip of the last twist. Finally, when we twist the three large strands into a cable, by a right to left twist, we enlist the tendency of every single fibre to untwist in binding our whole cable together.



238. FOREBOARD AND TRAVELLER (Thomas Barraclough, London)



239. HORIZONTAL STRANDING MACHINE (Thomas Barraclough, London)

If we try to break up a cable by loosening the strands and threads, we have against us the natural effort of the fibres to free themselves.

Two Methods. Rope-spinning has taken two forms—the factory method and the rope-walk. The latter is the old hand method to which machinery has been applied. The factory method consists in the application of the twisting of textile fibres to be seen in all factories, but on a gigantic scale, and with machines correspondingly large. The rope-walk, as the oldest, and, in the opinion of many, the better, may be studied first.

Rope-walk. A rope-walk may be any length, from 70 to 300 yards. It is a long, covered-in shed, laid with a series of rails along which run the spinning machines which have displaced the human rope-spinner—in this country, at least.

Creel. A V-shaped board, bearing as many as, perhaps, from 270 to 333 spindles for holding bobbins, is placed at the head of the walk. It is from this that the rope yarns are drawn.

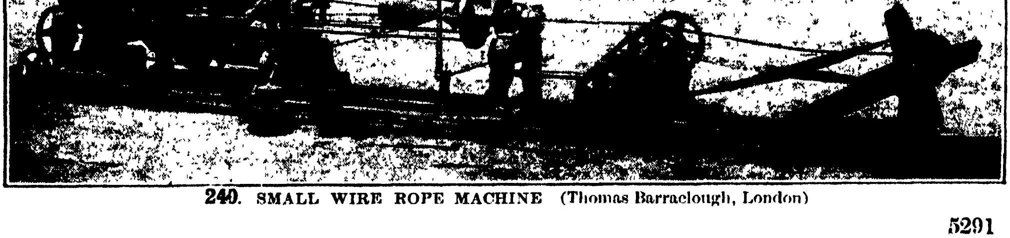
Register Grid and Plate. Before the creel stands what is called the *register*. This is a frame containing iron rods, forming little squares, with a plate in front of it, into which several series of concentric holes are drilled. From the creel the yarns are led through both grid and register plate. The latter may have nine concentric holes in a circle of eight, with one in the centre, or nine circles, each containing 27 holes, or any multiple of three or nine, according to the size of rope to be made.

Foreboard. Further in we find a heavy carriage [237], sitting on the head of which is a square box, with tubes running through it, and on the breast of the machine a set of large hooks. The box is the steam chest, kept constantly heated by a steam pipe, and the tubes are the passages in which the yarns are gathered, and through which they pass to become strands. The hooks in front are set in a circle round one large hook. On these the strands are linked when made, to be twisted together again into thicker strands.

Traveller. Two lines of rails run from the front of the foreboard, and away down the rope-walk. Upon these rails stands what we call the traveller [238]. This is almost an exact counterpart of the fore turn, without the steam chest, and it is set on wheels which run on the rails of the rope-walk. The hooks of both foreboard and traveller are fixed on spindles, which are made to revolve by means of wheels driven by the rope pulley at the side of each machine. These wheels are change-wheels, the size being according to the speed of revolution required. By means of clutch gearing, the revolution of the hooks can be reversed. Upon the traveller are strong brakes for controlling its speed, and a platform for the workmen.

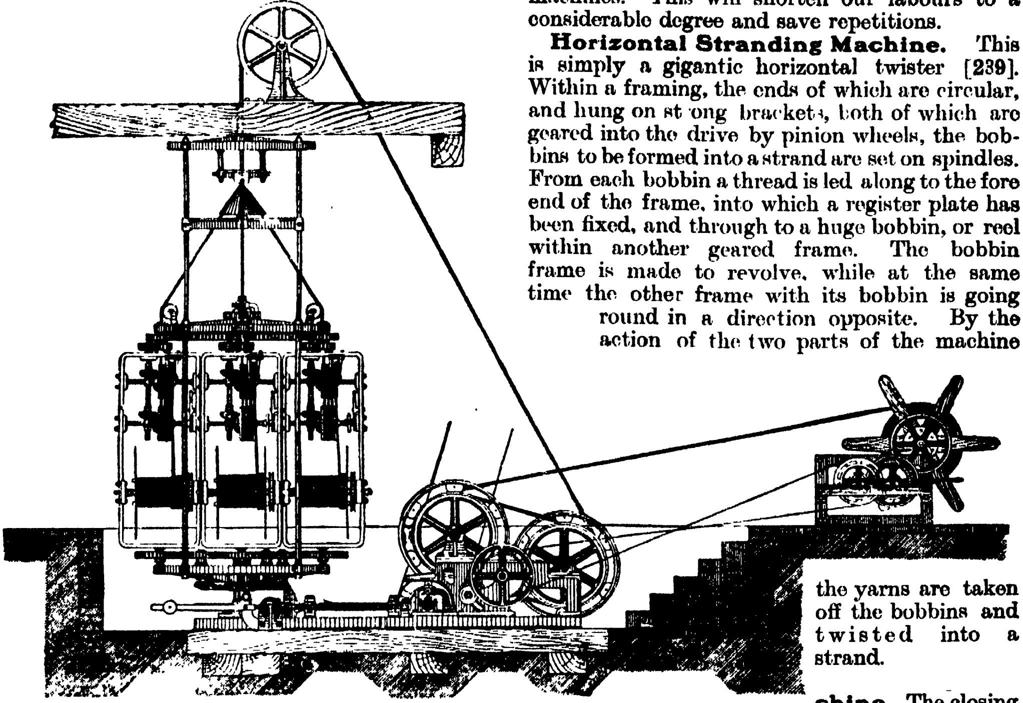
Gates and Posts. To complete the furnishing of the rope-walk we require gates and posts. These are the rests upon which the long lengths of strands or ropes are supported as they are being formed. The gates close behind the traveller as it comes along the walk, and the posts stand beside the walk with forked heads, into which the rope may be laid.

Making the Rope. The yarn bobbins are set on the creel, and led through the grid and register plate in sections. The bunches are



240. SMALL WIRE ROPE MACHINE (Thomas Barraclough, London)

gathered in the strand tube, and are tied on to nine hooks on the breast of the traveller. Away goes the traveller down the walk, drawing out the yarns to the full length. When the traveller has reached the end of its journey the yarns are cut and tied on to the hooks of the foreboard. As the traveller passes down, the gates close after it, supporting the formed strands. These have been twisted from right to left. When thus twisted the ends are transferred to the hooks on the foreboard, and between them the traveller and foreboard form the strands into three, by a left to right twist. Now comes the final operation—the laying of the cable. A bight is formed on the ends of the strands joined into one, and this is linked on to the centre hook of the traveller. What is called a *top*, a block of wood mounted on a bogie, is brought close up to the traveller. The hooks on the foreboard keep turning to maintain the former twist on the strands, while the traveller powerfully twists the strands into one, driving the top before the twist. By its weight, assisted by the powerful brakes, the traveller prevents the rope from curling up under the strong pull of the twist. When the cable has been laid it is wound by powerful winches on to a coiling drum.



241. CLOSING MACHINE (Thomas Barraclough, London)

Other Ropes. We have viewed a cable being made in one operation; but that is very seldom done. The strands are often made one by one. Then there are hawsers, made of three thick strands separately laid, besides thinner ropes, generally composed of three strands of from two to six strands each.

Tarring Ropes. Most cables and hawsers are made up of tarred strands. These are run through a tarring machine, closely resembling a twine-dressing machine in principle. After the tar has been put on, the strands are allowed to mellow for some time.

Factory Rope-laying Machines. It is undoubtedly owing to the invention of this class of machines that the wire rope business has been developed. In studying the process, therefore, we have to keep in mind that wires, as well as fibrous yarns, may be on the machines. This will shorten our labours to a considerable degree and save repetitions.

Horizontal Stranding Machine. This is simply a gigantic horizontal twister [239]. Within a framing, the ends of which are circular, and hung on strong brackets, both of which are geared into the drive by pinion wheels, the bobbins to be formed into a strand are set on spindles. From each bobbin a thread is led along to the fore end of the frame, into which a register plate has been fixed, and through to a huge bobbin, or reel within another geared frame. The bobbin frame is made to revolve, while at the same time the other frame with its bobbin is going round in a direction opposite. By the action of the two parts of the machine the yarns are taken off the bobbins and twisted into a strand.

chine. The closing machine [241] is simpler than its stranding assistant, but somewhat different in structure. The bobbins are fixed in a frame upon spindles which have a revolution of their own while carried round by the containing frame.

Through a plate in the head of the frame the strands are drawn into the closing tube, through tempering apparatus, and out on to the creel, or barrel, which, by differential gearing, is enabled to take on the rope evenly as it fills.

A Small Machine. Thin wire ropes are made on this machine [240]. First the wires are made into strands, by being placed within frames which have a flying motion. Between this frame and the laying apparatus is a stretching appliance, composed of coned rolls, one large and one small, the strands passing round both to be stretched and straightened. The whole framing next revolves, and, as the strands, three, or four, or five, come into the central twister, they become united.

Group 4

BUILDING

37

Continued from page 5187

By WILLIAM J. HORNER

HAVING dealt with doors and windows, which, with staircases to follow, constitute the main work in joinery, we now have a large variety of other work which it is neither possible nor necessary to take in detail. In the interior fittings of shops, public buildings, ships, railway cars, and in the construction of plain furniture, and numerous other articles of wood, there is too much to attempt to take individually. Instead, therefore, of giving full details of a few specific constructions, which would involve more or less repetition, we will turn attention to principles, and to details which vary.

Panelled Frames. Large panelled surfaces are often required for partitions, counter fronts, screens, backs of bookcases, show-cases, and articles of furniture. They may consist either of one frame of the size required, or of separate ones secured edge to edge. The tenoning of rails, stiles, and muntins, and the grooving for panels is identical in all cases, and has already been described; but the arrangement varies with circumstances. A large frame in which a number of rails and muntins cross is more troublesome to make and weaker than a number of narrow frames employed to cover the same area. The latter, therefore, are generally preferred where circumstances permit. In many cases their connection to the other portions of the structure is sufficient to keep them in position in relation to each other, as when attached to the back of a large bookcase or to the floor and ceiling at bottom and top. The joints between them are usually tongued and beaded, unless covered by other parts. When the panelled work stands alone, as in the case of a screen, the top may be grooved for a strip of iron, which keeps the parts in line and holds them together, as in **103**. Or a continuous capping piece alone may serve the same purpose.

Joints are concealed as far as possible by carrying them along the quirks of beads, as shown. Handrail bolts or screws may also be employed to hold the parts together. Rods may be carried up at intervals to keep a screen upright, and brackets attached to the floor, but these latter are employed only when no better means are possible.

Fig. **104** shows a form of joint often employed for the muntins in counter fronts instead of a mortise and tenon. The top and bottom rails are thus continuous, while the muntins are carried through on the outside.

Counter and Table Tops. Except in very rough work these are secured so that some lateral freedom is allowed for the shrinking and swelling that is unavoidable in great widths. The usual method is by means of *buttons*. Fig. **105** is a view of the under surface of a table top showing how it is held to the frame by buttons. They are screwed to the under surface of the top and fit into grooves in the end rails, and sometimes clip over a rebate on the edge of the cross bars which are fitted to intermediate parts of the frame. Another method of allowing lateral adjustment to wide pieces is to screw them, but to cut slotted holes for the heads of the screws. This is often done in attaching cleats to drawing boards. Tops usually have to be glued up to the required width, preferably with tongued or dowelled joints.

End joints in counter tops are often pulled together by the arrangement shown in **106**. Three strips are secured to the under surface, as shown: two of them on one of the portions to be joined, and one of them on the other, with about half their lengths overlapping, so that when the parts are together the single one fits between the other two. Slots are cut in them, arranged so that folding wedges driven through pull the parts tightly together. The unattached ends of the strips are then screwed to the surface also. The joint may also be tongued.

Thickening Up of Edges. Table and counter tops are usually thickened, as shown in **107** to **109**, by attaching narrow pieces to their under edges. This improves the appearance and slightly adds to the strength. There is seldom any necessity to have a top more than 1 in. thick, but they are thickened at the edges to appear from twice to three or four times that amount. Fig. **108** is a plan view of the under face of **107**, showing that the grain of the thickening pieces should run with the grain of the top. If the piece across the end had its grain transversely, shrinkage of the top would break the glue joint, and if it was screwed instead, there would be a risk of the top splitting. But in addition to this, the main purpose of thickening is to make the top appear thick, and this effect would be lost if an end did not show end grain throughout. Fig. **110** shows a more elaborate method of thickening up the front of a counter top, and of supporting the overhang by brackets or trusses against the front frame.

Cases. Glazed show-cases are generally required to be dust-proof, and consequently airtight. This is accomplished by intricate joints in which rebates, tongues, and beads, fitting into corresponding grooves, are freely used. Velvet and rubber are sometimes inserted to ensure a close joint between surfaces. Glass is often bedded on some such material to lessen risk of its getting jarred or strained by warping of the wood. In many instances also, the joints must be elaborately made, to ensure as strong a union as possible between slender rails, posts, and bars, which are rebated to receive glass. They often appear as a plain mitre joint on the exterior, but are generally a pair of secret dovetails or a pair of thin tenons, arranged according to the shape of the parts.

Plinths and Cornices. In joinery, these terms apply to projecting moulding attached to the bottom and top edges of articles. The moulding at the base is called a *plinth*, and that at the top, a *cornice*. A cornice is purely ornamental. A plinth is, in many cases, necessary to protect more delicate parts of the base from injury, or to raise them to a convenient height. Figs. **111** to **117** show examples of plinths and methods of attaching them, and **118** to **120** show cornices. A plinth has to carry, or assist in carrying, the weight of the structure above, and therefore should be substantial and properly attached. It may be either attached to the sides or placed beneath. In the first case it either merely thickens up the lower portion, as in the box shown in **111**, or is screwed to a skeleton base formed by projecting horns of stiles. This might be the case in **112**, but is shown distinctly, though in rather complex form, in **117**. In **113**, the plinth is a deep framework on which the upper structure rests. In such cases, the two parts are usually not attached, but one merely rests on the other, and they are kept in lateral position by blocks, which are screwed to the under surface of the upper part, and fit within the framed plinth. This is done in heavy articles of furniture so that they can be conveniently moved in parts. Cornices are sometimes put on similarly. In **114** the block beneath is supposed to be carried entirely round the base. It would be a very satisfactory alternative method of treating the box shown in **111**. In **115** the plinth is rebated, and is held in place by blocks glued into the interior angle. Fig. **116** shows a plinth beneath, with the bottom board tongued into it.

Cornices are attached in any convenient manner, being screwed either to top or side, or held by blocks glued in the angle. Fig. **118** shows the usual method of attaching a cornice to bookcases and wardrobes. The moulding is wide and thin, and has its edge bevelled so that when screwed on the upper surface, its front slopes outward, as shown. Sometimes glue blocks are fitted in the interior angles. To cut the ends of the mouldings to the correct angle for the joints, the moulding must be tilted in the mitre-box to its proper position, and the sawcut may then be made in the usual way. Figs. **119** and **120** show cornice moulding attached to the front.

Blocking and Screwing. Wood blocks, glued into interior angles to unite parts, as shown in **121**, A and B, are very commonly used in joinery and cabinet work. They are shown in **121** joining two pieces at a right angle, but they may, of course, be planed to fit any angle. At A the block is square in section, and at B triangular; but the outward shape is usually of no importance, as they are used in places where, under ordinary circumstances, they will be out of sight in the finished work. The alternative to the blocks is to use screws, as shown in **122** at A and B, and in end view in **123**. When there is no objection to a hole in the outer edge, the most direct method is to put the screw in as shown at A in **122** and **123**. The other method is to insert it at an angle through the side, gouging ou sufficient room for the head to go down, as at B. These methods are practised solely to avoid putting screws or nails through from the front of the work, where their appearance would be objectionable. Otherwise, in the examples shown, screws put through from the other side would be decidedly better and stronger.

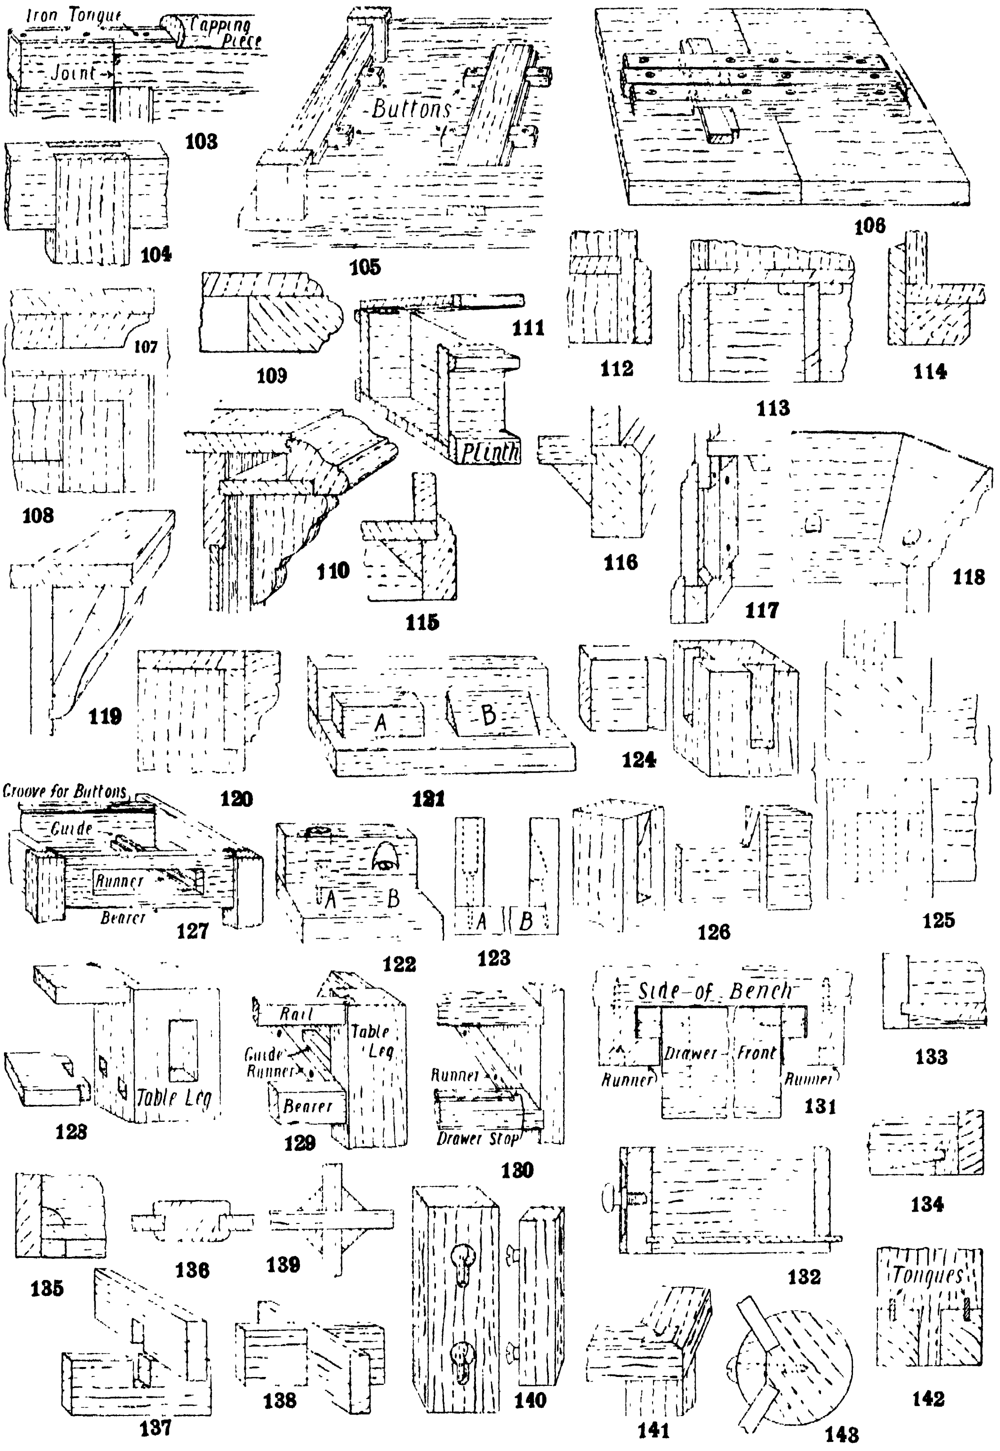
Frames for Plain Tables. These consist of legs held together by rails which are tenoned or dovetailed into the tops of the legs. Where extra stability is required, rails are also fitted between the lower parts, but this is avoided if possible. The method of dovetailing is shown in **124**. Tenons are shown in plan and elevation in **125**. In the example shown they meet with ends mitred, but in some cases they could be shorter. The upper part is haunched. Fig. **126** is another form of haunch which was not shown in Carpentry. A haunch cut in that way is not visible when the parts are together. In the frame of a table the parallel haunch in **125** is quite satisfactory because it is covered when the top is on.

When the table is of considerable length, or when the ends of drawer runners require support, one or more intermediate cross rails are inserted. Examples of these are shown in **105** and **127**. In the latter figure the front rail is shown cut to receive a drawer, but a better method is to fit separate rails above and below, as in **128**.

Runners for Drawers. The runners can then be screwed or nailed against the inside faces of the longitudinal rails, as in **129**. Runners form ledges on which a drawer rests and slides. When the part beneath a drawer is closed in by a dust board the drawer slides on this, and runners are not necessary. Besides surfaces to slide on, drawers require guides at the sides, and a stop of some kind to stop them at the correct position when being closed. In a construction like **130**, the sides of the article act as guides for the drawer, but in tables it is generally necessary either to rebate the runners, as in **127** and **131**, or nail guide strips on, as in **129**. The drawer shown in **131** differs from the previous examples in having the runners at the top and strips screwed to its upper edges to fit them. This is done because it is more convenient to screw runners to the under edges of the bench than to box the drawer in to enable it to rest on its bottom. Another method, suitable for cases containing a large number of shallow drawers, is to arrange the runners about midway in the drawer depth and to groove the drawer sides to fit them. The drawers then can be close together without bars between. When closed to the proper extent a drawer may be stopped either by a rail at the back or by blocks on the runner, or at the front by a thin strip, as in **130**, which stops the drawer front, but allows the raised bottom to pass over it.

Drawers. A longitudinal section through a drawer is given in **132** to show the ordinary arrangement of the parts. The bottom is thin, and usually chamfered down at the edges to fit in grooves which are ploughed in the front and sides. The back is reduced in depth, so that the bottom can be slid in after the front, sides, and back are framed together. Another reason for this is that the bottom can then be allowed to extend a little beyond the back, thus allowing ample for shrinkage. The bottom may be prevented from coming out of place by putting a screw through it into the drawer back. It will then shrink back from the front, and if in time it comes out of the front groove, the screw may be taken out and the bottom pushed forward and re-screwed. A portion of an end view of a drawer is shown in **133**, where the bottom fitting in its groove in the side is viewed from the back of the drawer. Figs. **134** and **135** show other methods of fitting the bottom without grooving the sides; **136** is a muntin across the middle of the bottom of a very wide drawer, the bottom then being divided into two panels. The grain of a bottom should always run across parallel with front and back, so that shrinkage can be allowed for as just described. In a rough drawer like **131** the bottom is nailed on. The sides, front, and back of a drawer may be either dovetailed or nailed together, according to the quality of the work. When dovetailed they are glued, and usually not nailed as well. Fronts are nearly always lap dovetailed, and are then thicker than the sides and back.

Miscellaneous Work. Deep pieces which cross each other, as in partitions in boxes and drawers and many other articles, may be halved, as in **137**, and appear when together as in **138**. This is generally the strongest and simplest method, but when there is any reason why one of the members



JOINERY

Joint in panelled frame **104.** Forked tenon **105.** A table top buttoned to its frame **106.** Joint drawn together by wedges **107-109.** Thickened edges **110.** Counter top **111-117.** Examples of plinths **118-120.** Cornices **121.** Glue blocks **122** and **123.** Concealed screws **124.** Rail dovetailed into table leg **125.** Rails tenoned into table leg **126.** Haunched tenon **127.** Runner supported at back by rail **128.** Rails for drawer **129.** Guides and runners for drawer **130.** Another arrangement for a drawer **131.** Bench drawer **132.** Section through a drawer. **133-136.** Details of drawers **137** and **138.** Example of halving **139.** Blocks in corners **140.** Secret fixing **141.** Box tenon **142.** Tongues in a wide tenoned joint **143.** Method of holding glass in a rebate should not have its strength diminished in this way, it may be carried through entire, and the other fitted and secured in any convenient way on each side. Sometimes the cut piece may have its ends housed or veed into the other, or blocks may be glued in the corners, as in **139**.

When parts of highly finished work have to be attached without showing any exterior sign of the means of connection, and where a glued joint is unsuitable, the method shown in **140** is adopted. Screws are inserted in one piece with their heads left about ½ in. above the surface, and slots are cut in the other to correspond. The slot is made large enough at one end to receive the head of the screw, and the remainder of its length fits the shank or body of the screw. The parts are put together with the heads inserted in the large holes, and they are then forced along the slots, the heads cutting their own way and keeping the parts together. The slots should be arranged so that the parts are in correct position when the screws have been forced nearly or quite to the ends. Either mallet blows or pressure may be employed, and care should be taken to keep the parts in close contact while it is being done. The slots should always run with the grain. The parts can be separated by knocking back again. When in a vertical position, the direction for fixing should be downwards.

Figure **141** shows a form of tenon sometimes used at mitred corners of frames. Fig. **142** shows how a wide member with a single tenon may be prevented from tendency to twist, by inserting tongues; **143** shows the usual method of securing glass in the bars of shop-fronts and cases.

Curved Work. Curved surfaces are formed by bending, by working out of solid wood of sufficient bulk, or by building up a number of pieces arranged according to the contour desired, and then working the whole to shape. The last method is in most cases the best, and often is the only practicable one, but circumstances always decide.

Pieces of wood that are sufficiently thin in proportion to their length can be bent considerably without fracture. If the bending process is applied gradually, and especially if the wood is first soaked in hot water, or preferably steamed, this amount is very much further increased. If, after steaming, the wood is secured till it is dry against a block formed to the required curvature, it will retain its curved form when released. The amount to which wood can be bent depends on its section, and on the kind of wood. Bending is nearly always practised lengthwise, and not across the fibres, for in width and thickness, material can easily be glued up and planed to any curvature. In many cases wood can be bent without special appliances, simply by screwing it in place, and so forcing it to accommodate itself to the sweep of the surface to which it is screwed. Or it will form a sweep of its own if it be bent and the ends immovably secured. When a number of pieces of similar curvature have to be bent, a suitable appliance is made. These appliances vary in form considerably, but the essentials are a surface of the required curve and means for gradually forcing the wood to that curve and keeping it there for several hours.

In rough work a common method is to weaken the wood by running saw-cuts across, as in **144**. This can usually be employed only in cases where the saw-cuts will be concealed, and therefore the uncut face of the wood should always be outwards, and the other against another surface. The cuts should be uniform in depth and distance apart, and spaced rather closely, but the outer face always shows more or less sign of a series of flats corresponding with the spacing of the saw-cuts. Figs. **145** and **146** show the piece bent to opposite sweeps.

Building Up. Figures **147** to **157** show various methods of building up; **147** and **148** are examples of plain circular plates. In **147** a number of boards are joined edge to edge to form the required diameter, and the whole is kept straight by battens. Instead of battens, two thicknesses of wood may be employed with grain crossed. Shrinkage in the first case results in the circle becoming more or less elliptic, and in the second in overlapping edges. In **148**, a plate is built up in a way that obviates diametral shrinkage, but at some sacrifice of strength. Two thicknesses are necessary, so that the segments may break joint. It is adopted chiefly in pattern-making, when the pattern is of a character that requires rims similar to **149** on one or both faces of the plate; **149** is a ring built in segments. In small rings the number of segments to a layer is usually six, and in large ones more. The end grain joints overlap in the layers as shown, and therefore, no matter how shallow the ring, there should be at least two layers or thicknesses, and preferably not less than three. Rings like this are usually turned in the lathe, but not necessarily so. One segment is marked out and sawn, and used as a templet to mark the others from. They are sawn roughly to shape, and the faces and ends fitted by planing them on a shooting board. They are glued and usually bradded as well. Where comparatively deep segments are employed, as in **150**, the end grain joints are often splayed and tongued, as shown. Fig. **151** shows narrow boards tongued edge to edge to form a curve, the edge joints being bevelled to the required inclination; **152** shows another method of forming curved work too large or too wasteful of material to be cut from one piece: **153** shows pieces halved together at a suitable angle to form a required curve; **154** is an example of staving up to form a cylinder or curved surface too large for solid wood.

Splayed Work. The heads and sides of windows and doorways are sometimes splayed, and also the sides and ends of hoppers and other constructions. Some marking out is necessary to obtain the angles at the joints: **155, A, B, C,** shows three views of a splayed construction, in which the angles of the sides in B are not the same as those of the top in A and C. The edges also are on one side bevelled and on the other square with the faces of the wood. The face view at A does not give the actual angles of the joints because the parts are viewed in an inclined position. The angles to cut the pieces to must be obtained by laying them out flat, as shown by the dotted lines on the left-hand side in A. The width of the inner face, 1 to 2, in B, is taken and transferred to A by adding the dotted line 1 at a corresponding distance from the inner edge 2. The actual length of each edge is already correctly given in A, and therefore the length of the outer edge is projected to the dotted line 1, and a diagonal drawn from that point to the inner corner on the line 2. These dotted lines give the angle to which the wood must be cut to meet the other correctly when the parts are tilted. If the angles of sides and top were alike, this would apply to all the pieces, but the top, being more sloping, must be laid out similarly from the view C. If the joints are mitred as shown, and the edges represented in an inclined position, as in A, the true angles of the mitre are obtained by transferring the actual thickness, **3** to **4** C, to A, and the side, 5 to 6 B, to the similarly numbered lines in A; 3 to 4 and 5 to 6 being tilted differently, it will be noticed, do not bear the same relation to the face lines in A. A diagonal from the inner to the outer corner of these edge lines gives the mitre. This, however, is always 45 deg. when the pieces to be mitred are of similar thickness.

Figure **156** is an example of a curved splay. A is a front elevation, B a vertical, and C a horizontal section. D is the inner curved surface of the splay supposed to be stretched out flat. A piece of paper or other thin, flexible material cut to this shape might be bent round, and would fit the inside of the splay. D is called a *face mould.* Such moulds are often employed for marking out the shape of work of complex curves. In this case it is not really necessary because the form is given definitely in the views A, B, and C, and material of the correct width would require only the semicircles marked on each face, and could then be worked in straight lines across from one to the other. The face mould is developed by continuing the lines of the splay in C till they meet at the centre O. From this centre the curves of D are struck, their starting-points corresponding with the edges of the face, and their length obtained by dividing the curve in A, and stepping off that in D to similar length.

Double Curvature. This is commonly known as *circle on circle* work. The form in which it is generally required is shown in **157**, A, B, and C. It represents the head of a door or window frame which is semicircular in elevation, as at A, and segmental in plan, as at B. C represents the side elevation. To form this two pieces may be jointed at the crown, or it may be divided into three or more parts according to its size. The elevation and plan being given as at A and B, it is developed in two parts as follows. The chord, 1, 2, is drawn in the plan, and the tangent, 3, 4, parallel with it. The distance between these lines gives the thickness of wood required. Face moulds D and E are made, and, when laid on the front and back faces respectively, serve as templets for marking the elevation curvature of A, on the flat surfaces, 1, 2, and 3, 4, and also the angles of the joints on the face. The moulds are obtained by dividing the outer semicircle in A into any number of parts, one of which is marked O, carrying vertical lines down from them to cut the line 3, 4, in B, and then carrying them back radially to the centre the curves of B are struck from, cutting the line 1, 2 in doing so. The line which starts from O in the elevation is also marked O at each of these two points in the plan. From these latter points lines are projected at right angles to the lines 1, 2, and 3, 4. The lengths of the vertical ordinates in A are now taken from the horizontal line up to each of the points where they intersect the outer and inner semicircles, and these heights are transferred to the corresponding ordinates which have been extended from the lines 1, 2 and 3, 4 in the plan B. The curves of the face moulds are then traced through the points thus obtained. The curvature in C is obtained by measurement with dividers from the straight lines 1, 2 and 3, 4, in B, to the curved ones contained within them, the measurements being made on the radial lines connecting the ordinates. If the jambs radiate as shown, this must be allowed for in placing the moulds.

Mouldings. The main elemental forms of moulding are shown in **158** to **173**. More complex forms are made up chiefly of a combination of these. The Grecian and Roman differ in form in some cases, though the same names are applied to both. The Grecian are generally considered more graceful, especially in curves like the ogee, which in the Roman change abruptly in direction. The Grecian curves are mostly elliptic or parabolic in form. The Roman are all parts of circles. The listel [**158**] is always used in combination with curves. The astragal [**160**] is a small semicircular projection running horizontally. When vertical, it is a cocked bead. When flush with the surface, with a quirk or groove at its side, it is an ordinary bead. The Roman torus [**163**] differs from it only in being much larger and having a fillet on one side. The Grecian [**162**] is a parabolic sweep projecting about two-fifths of its depth. The Roman ovolo and cavetto [**165** and **167**] are quarter-circles; the Grecian [**164** and **166**], are parabolic and elliptic curves. The cyma recta is two-quarter ellipses in the Grecian [**168**] and quarter-circles in the Roman [**169**]. The cyma reversa is, in the Roman [**171**], merely reversed in position; in the Grecian [**170**] its form is also modified. The scotia [**172** and **173**] is a compound curve in both Grecian and Roman, but proportioned differently. Except those which are parts of circles, none of the sweeps are rigidly fixed in contour, but are required merely to have a graceful appearance. Their normal proportions are indicated by divisions on the straight dotted lines. For working these mouldings by hand, planes of the correct form in various sizes are generally employed.

Enlargement and Diminution of Mouldings. The most convenient method of obtaining proportionate enlargements or reductions of mouldings is by means of radiating lines, as in **174**. The example shown is a plain cube, but if its form were irregular it could be treated in the same way by adding any number of intermediate radial lines.

A simple method of enlarging a moulding is shown in **175**, where A is enlarged at B by projecting parallel lines from it to cut a diagonal of the required length. The thickness of A may be increased similarly.

In **176** the moulding A is reduced to B by drawing horizontal and vertical lines from its chief points to meet the lines XX at right angles to them. From the points XX in each case equilateral triangles are drawn to the points O, and the intermediate lines from the moulding are converged to those points also. The lines 1 1 across these triangles represent the diminished size of the moulding, and the converged lines may be projected along to it in one direction and transferred with dividers in the other. If the moulding is to be proportionately reduced in both directions the horizontal and vertical lines 1 1 must bear a definite relation to each other. Supposing the longer or vertical one to be decided on first, the length of the other is obtained by taking the horizontal length XX and transferring it from X to 2 on the vertical line XX. From 2 a radial line is drawn to O, which gives the length 3 1 on the vertical line 1 1; 3 1 will be the required length of the horizontal line 1 1.

Raking Mouldings. When the ends of horizontal or vertical mouldings meet the ends of inclined ones, as in skirtings, pediments of doors and windows, and various constructions, the sloping joint of the inclined one must correspond in depth with the square end of the other, and the depth of each measured square across cannot therefore be the same. The entire contour of the moulding also must be correspondingly modified in cross section to make the two pieces match at the joint. In **177** we may suppose moulding fitted round a square body with a bevelled top. At A and C horizontal moulding is seen in end view, and at B a section is given of inclined moulding for connecting A with C. Supposing the section at A already decided on, the required sections of the other two are obtained as follows. With the exception of the fillet at the top the moulding has no definite points from which lines can be projected, and therefore it is necessary to divide the curve into parts. From the points 1, 2, 3, 4, 5, 6, lines are carried up to the horizontal line above, and transferred from there to the correspondingly numbered points on the slope, and from there continued across at right angles. Lines running parallel with the slope are also carried from the divisions on the curve in A, and where they intersect the other lines, points are given through which the contour of the inclined moulding is traced. The divisions on the top surface are again repeated at C, and the verticals carried down to intersect the lines parallel with the slope, giving another set of intersections through which the contour of C is traced. The curved line XX in the lower part of the figure indicates how a curved or *sprung* moulding would be treated, all the lines following the slope then being curved to correspond with it.

Figure **178** is an example of vertical angle bars of a shop window. Their ends are fitted to horizontal rails, and their points and backs are required to be in line, no matter what angle they lie at. The shape of the curved portion may be obtained by divisions as shown. Fig. **179** shows raking bars such as might be used in a lantern light or greenhouse roof. A is at the ridge, B and C are sections through two different slopes, and D is a horizontal piece at the eaves. In these there are no curves, and it is necessary only to draw lines from their angles.

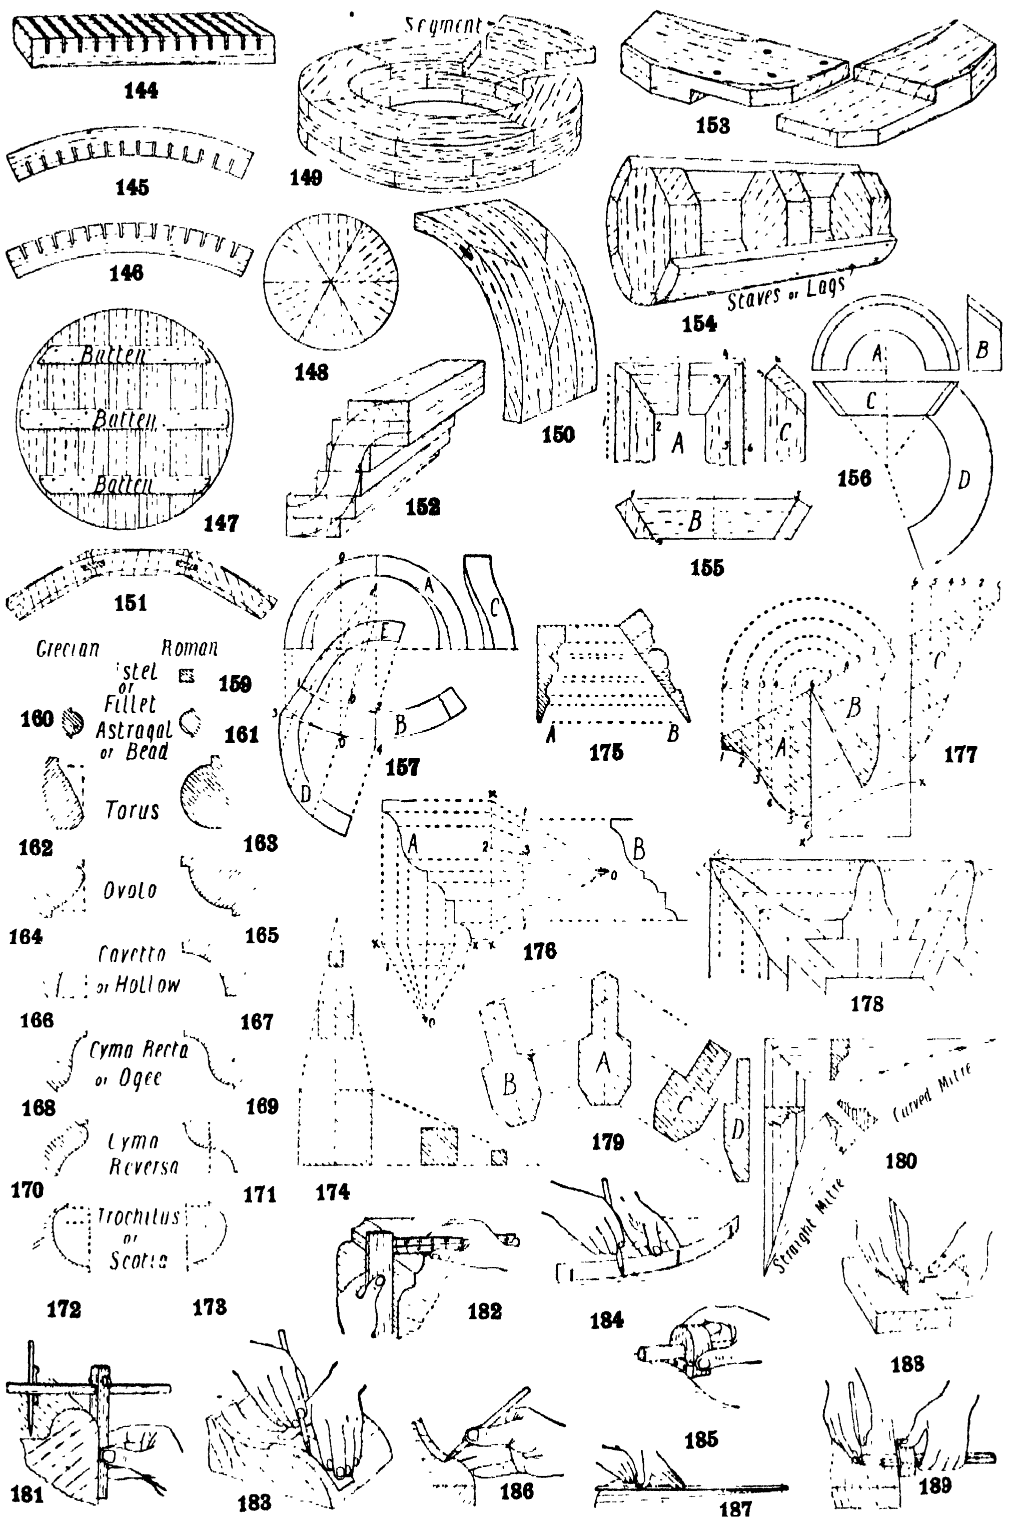
Mitres of Curved Mouldings. With these straight mitres can only be employed under certain conditions. Fig. **180** is an instance where a straight mitre necessitates making the section of the curved moulding different to that of the straight one which it joins. By curving the mitre, two mouldings of similar section may be made to match at the joint. The curve is obtained by running a number of lines parallel with each and tracing the curve through their intersections. The modified moulding is obtained by making its lines meet those of the other on a straight mitre. Curved mouldings of similar radius and section will join with a straight mitre when their concave or convex sides are towards each other, but not internal curve with external

Methods of Marking Out. The longtooth, or grasshopper gauge is used as in **181**, for gauging lines on different levels, or when an intervening projection prevents an ordinary gauge from being used. An alternative is to mark the distance at each end and rule a line through, but in some cases this is not possible. Measurements are made, as in **182**, when the rule cannot be applied directly from one point to another. A flexible strip of steel or wood is often used for marking curved lines, either on a curved surface as in **183**, or by bending it to a suitable sweep, passing through the points required, as in **184**. The alternative to **183** is to fit a piece of wood or cardboard to the contour and mark against one of its faces, or to gauge from an end face. Curved lines may be gauged parallel with a curved edge by using an attachment to the gauge, as in **185**. Fig. **186** shows a rough method of marking such a line by hand. Much trouble may be saved, in marking a number of radial lines some distance away from a centre, by driving a pin into the centre for the straightedge to bear against, as in **187**. Figures **188** and **189** show methods of gauging pencil lines when a considerable number are required alike. Fig. **188** is a block of wood rebated to the required distance and slid along the work with the pencil held against it or in a notch. Fig. **189** shows a gauge used similarly. Figs. **190** and **191** show an easy way of reducing the thickness of a piece of wood when it cannot be sawn. It can be cut with less effort when the tools are used diagonally across the grain than when in the same direction. The edges are first bevelled down to the gauge lines. Then, if the amount to be removed is very much, a gouge is used first, and then a jack plane until the surface is almost down to the gauge lines. After that the planing is done in line with the grain. Spokeshaves are used as in **192**, and drawknives as in **193**, with the work held in any convenient manner, usually in the vice. The spokeshave is used either from or toward the workman, as most convenient; the drawknife always toward.

Staircases. This, with handrailing, is a branch of joinery requiring special knowledge and skill. The arrangement of stairs should be decided on in planning a building, and the carpenter should consider them in laying the floor joists, as these latter sometimes have to extend through a wall to form a landing in the stairs. As in most other work, staircases are put together as far as possible in the workshop. Stairs should be arranged to make communication between floors as easy as possible. Two straight flights in opposite directions with a landing midway, are less tiresome to use than one continuous flight. A landing is also better than winding stairs at a turn. The latter are adopted only when the total rise and confined space demand it. The height and width of each step should bear a certain proportion to each other. An increase in one direction should mean a diminution in the other. Thus a step may be wide and shallow or narrow and high. If this rule is departed from, they are tiresome to use. A rise of 7 in. with a tread of 9 in. or 10 in. wide, is found the most convenient, but unless the total rise and total amount of *going* in the forward direction are adapted for this it has to be modified. The joiner marks the exact rise and going of his staircase on a storey rod, and from this the number and size of the steps are decided. A storey rod is simply a long rod about 1½ in. square, on which the total lengths are marked.

The individual steps of a staircase have to be secured at their ends to timbers called *strings*, which follow the slope of the staircase, and when the width of the stairs is considerable, or when laths for plaster have to be nailed across the under surface, one or more intermediate *carriages* are added. Landings and the ends of strings and carriages are supported by joists from the walls, and often also by newel posts extending to the floor below. The boards of landings are usually buttoned instead of nailed to the joists. Where flights of stairs occur above one another a height of not less than 6 ft. must be allowed between the nearest points for headroom. Staircases usually have a wall on one side while the other is open and provided with the handrail and balusters.

Principal Types of Stairs. There are four principal types of stairs, three of which are shown in plan in **194** to **196**. The simplest kind are straight, consisting of one flight, sometimes with winders at the bottom. *Winders*, which is the term applied to winding or radiating steps, are never used at the top of a flight if it can be avoided.



JOINERY

The next form is shown in **194**. These are known as *dog-leg*. They consist of two or more straight flights running in reverse directions, either with or without winders at the turns, and with their handrails in the same vertical plane.

The foregoing are the two commonest types. The others occupy more space and are used chiefly in high-class houses and public buildings. One is known as the *open well*, or *open newel*, type [**195**], and the other as *geometrical* stairs [**196**]. The open newel, in common with the straight and dog-leg types, have newel posts at each change of direction in the stairs and handrail. They differ from the dog-leg in having lateral space, called a *well*, between the flights. In making a turn the flights then are generally at right angles with each other instead of turning a semicircle from one flight to the next. Geometrical stairs may be of several varieties, but they differ from all the foregoing types in having no newel posts, the handrailing and stairs being made to change direction without sharp turns. These must not be confounded with spiral stairs, which have a central newel.

Details of Strings and Steps. Figure **197** is a back view of a portion of a straight flight supposed to be on the bench in course of construction. The strings usually differ in character as shown. The one which goes against the wall is a parallel board 1½ in. or 2 in. thick with recesses ⅜ in. or ½ in. deep cut in its face to receive the ends of the steps. These are tightened by wedges as shown and afterwards nailed from the other side, besides having glue-blocks in the interior angle. Sometimes the string is thickened up by nailing brackets within to supplement the depth of the housing. The other string has its upper edge serrated to the shape of the stairs, and the ends of the *treads*, or horizontal boards of the steps, rest on it. In cheap work they project an inch over to form a nosing similar to that on the front edges of the treads. The baluster ends are then housed about ¼ in. into it. But the usual method is to dovetail them in at the side and fit the nosing on after, by tonguing, secret screwing, or roughly by nailing. The front and side nosings are mitred at their joint. The *risers*, or vertical boards of the steps, are usually stop mitred to the strings as shown. Another method is to mitre them to ornamental brackets as in **198**.

Steps are first glued up separately as in **199**. Figures **200** to **203** show various methods of jointing the treads and risers. Fig. **203** is known as *slot screwing* and is a plan adopted in many other instances. It allows the tread to shrink or swell in width without breaking the joint or splitting the wood. The recesses for treads and risers in the wall string are marked out by templets of similar length and thickness to those parts plus the amount for wedging. The steps are afterwards fitted separately and numbered ready for the final gluing up. The positions of the steps on the string are marked by a templet called a *pitch board*, which is a thin triangular piece of wood with two of its edges at a right angle representing the length and depth of one step. This is slid along the string against a guide behind it, which keeps its point to the nosing line of the stairs, and its angle in correct position. This is used on both housed and *cut* strings. The latter name is given to strings which are notched out, as in **197** and **198**. Occasionally, housed strings are fitted to the outer side of a staircase, but usually they are on the wall side and the outer ones are cut.

Landings and Winders. Landings are either half or quarter space, according to whether they extend across the width of two flights, as in **194**, or only one flight, as in **195**. The usual method of arranging their joists are shown in those figures. Winders at quarter turns are divided into three, as **195**, and templets made to mark the shapes of the treads by. The ends of the treads and risers that radiate from the newel post are housed into it.

It is bad practice to have the nosing of a winder radiating into the angle of the walls. It should be divided as in **195** and **196**. It is best, also, instead of radiating from the centre of the newel, to make the treads as wide as possible round the newel. Winders generally have to be built up in place, but as much as possible of the work is done in the shop, where there are better facilities for doing everything.

Newel Posts. These are 4 in. or 5 in. square, with portions turned. In some cases they extend to the ground floor and help support the staircase, while in others their chief purpose is to support the handrail, and they terminate a few inches below the string in an ornamental end. Where they are employed the strings are tenoned into them as in **204**, and pinned. Newels are secured to joists by bolting them against the side, generally with a cogged joint. This is done at landings where a joist or trimmer crosses the newel, and at the base when newels extend to the ground floor.

Carriages. The under edges of these should be flush with those of the strings. To avoid great depth they are generally stiffened and made to afford support to the treads by nailing rough pieces on either their sides or upper edges as in **205**, A, B, C. Their ends are fitted to joists or trimmers as in **206**. Under winders they are framed into *pitching pieces*, which are fitted between newel and wall.

Bullnose steps are formed by bending thin wood round a rough interior block, as in **207**. The riser is sawn down thin where it is to be bent, and is glued and tightened by wedges at one side. Screws are afterwards put through into the thick part as shown.

Geometrical Stairs. These have no newels to receive the ends of handrails at the turns, but the rail is supported entirely by balusters, and changes its direction in curves. The outer string also must curve similarly round the well. This may be done either by staving it up or by reducing its inner face to a veneer, and bending it round a cylinder of the required size and gluing staves on the back [**208**]. Another way is to bend and glue several thicknesses of thin wood together round the cylinder, keeping them there till the glue is set. Fig. **209** shows the method of obtaining the stretched out shape of a semicircular bend like that in **196**. The divisions on the line XX represent the semicircle stretched out flat. This may be done in a number of ways. The one shown is by projecting lines from an equilateral triangle through the points on the curve. From the line XX they are carried in parallel lines giving the tread widths. The drawing is developed by adding the riser heights, which are all alike.

Handrailing. In stairs with newel posts the handrail is usually straight and tenoned into the posts at each end. Its inclination follows that of the staircase. Its height should generally be 3 in. or 4 in. more on a landing than on the stair incline. Its inclination over the narrow ends of winders is naturally much greater than over full-

width fliers, and therefore its height above the treads of winders should be correspondingly diminished to make it convenient for use. For this reason straight rails are sometimes curved in elevation at each end, as shown in **210.** In geometrical stairs the handrail is supported only by the balusters beneath it, and is winding or twisted in form to follow correctly the turns round the well while rising simultaneously with the stairs. These are termed *wreaths*, and the work connected with them, and often the proportioning of the steps below them to obtain a graceful sweep, is done by specialists. The principle on which a wreath is formed is shown in **211**, which gives elevation and plan of a semicircular wreath. The actual marking out involves a great deal of geometry, and to go into details would occupy more space than can be afforded in this course. The joints in rails are usually square, and are held generally together by a handrail bolt and by two dowels.

Balusters. Balusters may be housed or tenoned into the under surface of the rail, or skew-nailed either into a groove or merely against the surface. A very substantial method often adopted for geometrical stairs, is shown in **212.** An iron core is screwed to the tops of the balusters, and this is screwed into a groove in the under surface of the rail. Balusters may be either plain square rods, or rendered more ornamental by having their middle portions turned. The turned portions should be of similar length, and follow the angle of the string and rail, the square ends being varied in length according to their positions on the treads. In most cases two balusters occur on each tread, one over the nosing, and the other equally divided horizontally between that and the next nosing. The dovetails are marked by templet on the ends of the treads. In geometrical stairs iron balusters of similar pattern to the wood ones are placed at intervals to afford substantial support to the handrail.

THE WORLD'S MINERALS

Coalfields and their Resources. Petroleum and its Uses. Iron and Steel. Gold and Silver. Other Metals. Precious Stones

By Dr. A. J. HERBERTSON and F. D. HERBERTSON

is derived from the vegetation of past geological epochs, subjected for vast periods of time to great pressure and heat. The result of a long series of slow chemical changes is to get rid of a large proportion of the hydrogen and oxygen, and to increase the proportion of carbon [see NATURAL HISTORY]. *Peat*, abundant in the bogs of Ireland and other parts of the world, shows an early stage of the process. The fibrous arrangement is still clearly seen. There is a large proportion of water, and owing to the smaller proportion of carbon the heating power of compressed peat is only about one quarter of that of coal. *Lignite*, with 70 per cent. or less of carbon, is intermediate between peat and coal, but the harder varieties, known as brown coal, closely resemble the latter. Some of the vast lignite deposits of North America are an excellent substitute for coal.

The Two Kinds of Coal. Of coal there are two well-marked kinds—soft or bituminous coal, with 50 per cent. or more of carbon, and anthracite, with as much as 94 per cent. *Bituminous coal* lights readily, burns with a flame, and produces a varying amount of smoke. Its varieties are very numerous, one of the best marked being the well-known cannel coal. *Steam coal*, intermediate between bituminous coal and anthracite, contains little bitumen, so that it is smokeless, while the high proportion of carbon gives great heating power. This steam coal is in great demand for naval use. *Anthracite* is hard to light, burns without flame, and gives out great heat. Its smokelessness makes it very suitable for use in cities, as in the United States. It is also used in brewing.

Coke is produced by heating bituminous coal away from the air. The volatile substances are driven off, and the residuum approximates in properties to anthracite. Coke is an important by-product in the manufacture of coal gas. It burns with intense heat, and its freedom from sulphur makes it valuable in many metallurgical operations. Coals are often spoken of as coking, or non-coking. The former, which cake or fuse in burning, are preferred for special purposes—for example, as fuel for locomotives.

Growth of the Use of Coal. The use of coal is of no great antiquity in Europe. Whatever may have been the case locally, it was not used in London before the thirteenth century. In the seventeenth century the total production in England had reached over 2,000,000 tons. The introduction of steam power enormously increased the consumption of coal, and resulted in a redistribution of population in England and other countries.

Coalfields of the World. Estimates of the total area of the World's coalfields differ widely. The area can hardly be far under 500,000 sq. miles. According to Mr. Chisholm, there are approximately 250,000 sq. miles in North America, chiefly in the United States. The coalfields of China cannot be less than 200,000 sq. miles, and may be more. The coalfields of Britain may be put at about 12,000 sq. miles, while those of the Empire are roughly 140,000 sq. miles. Russia has about 20,000 sq. miles; Spain, 5,000; France, Germany and Austria-Hungary, round about 2,000; and Belgium, 500 sq. miles. Area, however, affords no satisfactory basis for estimating the actual resources. Much coal lies at a depth impossible to work, as, for example, on the South Wales coalfield, where the coal-bearing strata are 10,000 ft. thick. In other cases the seams may be so thin as not to pay for working, or the quality may be inferior. Temperature increases rapidly though not uniformly with the depth of a mine, rendering extraction beyond a certain depth a physical impossibility [see MINING]. The element of cost has also to be taken into account in deep mining. At the present time a depth of 4,000 ft., and a seam thickness of 2 ft. are commonly assumed as working conditions. No mine yet reaches this depth, though the deepest mines of this country and of Belgium are not far short of it.

How Long Will Our Coal Supply Last? The ever increasing demand for coal has led to investigations into the probable duration of our coal supply. Two Royal Commissions have reported on the subject, the second in 1904. On the workings of 1903 our reserves would apparently last for 600 years, but the output is not likely to remain steady. More probably it will reach a maximum within no distant period, and then almost imperceptibly decline owing to the gradual increase of working cost.

The largest coalfields of Britain are those of (1) Central Scotland, in the rift valley between the Scottish Highlands and the Southern Uplands; (2) South Wales; and (3) the marginal coalfields of the Pennines in the north-east, south-east, and south-west.

The Coalfields of Scotland. The Scottish coalfield is divided into the Ayrshire coalfield, the Central, or Forth and Clyde coalfield; the Fife coalfield; and the Midlothian coalfield. The estimate furnished to the Royal Commission of 1904, was that more than 15,000,000,000,000 tons are available, including workable coal under the Firth of Forth. The bulk of this is in the counties of Fife (with Kinross), Lanark, the

Lothians, Stirling and Ayrshre. The output for 1904 was 35,500,000 tons, half of which was from Lanarkshire, which feeds the great industrial region of which the Clyde is the centre and outlet.

The South Wales Coalfield. The South Wales coalfield ranks next in size, with an area of over 900 sq. miles. Deeply cut valleys penetrate into this mountainous region, bringing the outcrop to the surface and enabling the seams to be worked cheaply. This explains why the mines were long and shallow as compared with those of the North of England, though many are now carried to over 10,000 ft. The ports at the mouths of the valleys, of which the most important are Llanelly, Swansea, Cardiff, Barry, and Newport, are well placed for exporting coal cheaply. Much is used locally for iron smelting, the tin plate manufacture, etc. The eastern part of this field consists of bituminous coal. The centre supplies most of the steam coal for the Navy, while anthracite is mined in the western part. More than 26,000,000,000 tons are estimated to be available within 4,000 ft., half being steam coal. At the rate of output in 1903 (42,000,000 tons) this would last about 600 years.

The Coalfields of the North of England. The coalfield of Yorkshire, Derby, and Nottingham, the largest in England, is about 750 sq. miles in area. The Silkstone is one of the best seams. It is continuous with the Arley coal of the Lancashire coalfield, and must originally have covered an area of 10,000 sq. miles. The Barnsley coal is of a semi-anthracite character, developing a great heat either as engine or smelting fuel. The estimated amount of workable coal in 1903 was over 26,000,000,000 tons, available for 500 years at the rate of 1903 (52,000,000 tons). This coalfield supplies the Yorkshire woollen and iron industries.

The Durham and Northumberland coalfield also lies east of the Pennines. The seams which run under the sea might probably be followed for about three miles. A famous seam is the Wallsend, five or six feet thick. Newcastle coal is in great demand in London, and also locally for the vast iron industries of the Tyne and Tees. The output in 1903 was nearly 45,000,000 tons. The area of visible coalfields was estimated at 460 sq. miles, in addition to 225 sq. miles of concealed coalfields and 111 sq. miles under the sea. The estimated amount of workable coal was estimated in 1903 at nearly 9,000,000,000 tons.

Two important coalfields, those of Cumberland and Lancashire, lie on the western flank of the Pennines. In the Cumberland coalfield all the coal lies within 2,000 ft. of the surface. It is chiefly mined round Whitehaven, Workington and Maryport, and the workings have been carried about three miles under the Irish Sea. The amount of coal available has been estimated at 1,500,000,000 tons, which at the rate of 1903 (over 2,000,000 tons) would last about 700 years.

The South Lancashire coalfield, which extends into Cheshire, is an irregular area of over 200 sq. miles. Its output in 1903 was not far short of 25,000,000 tons, a great part of which feeds the great cotton and iron industries of Lancashire. The southern part of this coalfield is one of the most densely populated parts of Europe. The estimated reserve is 4,340,000,000 tons.

Coal for the Black Country. The North Staffordshire coalfield is not very large (75 sq. miles), but it has thick seams of workable coal. The coal-bearing strata are perhaps 5,000 ft. thick, with a total thickness of workable seams amounting to nearly 3,000 ft. Workings are carried down to nearly 3,000 ft. This region is not yet developed to anything like the extent possible, since few districts in the United Kingdom are so richly endowed with mineral wealth. The South Staffordshire coalfield, on the contrary, once enormously rich, has been much depleted to feed the furnaces of the Black Country. The whole country between Wolverhampton, Dudley and Birmingham forms one great workshop [see **72**, page 1274]. Professor Hull has vividly described the scene at night, as viewed from the walls of Dudley Castle, in the centre of the coalfield. "The whole country within a radius of five or six miles is seen to be overspread by collieries, iron foundries, blast furnaces, factories, and the dwellings of a dense population, and from amidst the thick smoky atmosphere the tongues of fire from the furnaces shoot up an intermittent light which illumines the whole heavens. But the spectacle does not represent the whole sum of human labour, for whilst 10,000 hands are at work above ground, one half as many, perhaps, are beneath the surface hewing the coal which is to be the prime mover of the whole machinery in motion above ground." The total thickness of the workable seams in the Dudley district is about 65 ft., a famous seam being the Ten-yard, with a general thickness of 30 ft. Probably nine-tenths of this rich seam are now worked out, drowned, or otherwise destroyed. In this area of 93 sq. miles, there were perhaps 1,400,000,000 tons still available in 1903, in which year over 13,000,000 tons were raised in the two Staffordshire coalfields.

The Warwickshire coalfield has the advantage of being the nearest to London. The area at present worked is about 30 sq. miles, with perhaps 30 ft. of workable seams. It may yield nearly 850,000,000 tons. The output in 1903 was rather under 3,500,000 tons.

Some Minor Coalfields. The Bristol coalfield, which extends to Gloucester and over much of Somerset, has two series of coal-bearing strata, separated by harsh sandstones. The total area has been put down at 150 sq. miles, of which all but 45 sq. miles are concealed by more recent formations. The output in 1903 was about 1,500,000 tons, and it was estimated that over 4,000,000,000 tons might be available. Of this more than one-eighth is steam coal, suitable for the Navy.

There are numerous smaller coalfields, such as those of North Wales, Coalbrookdale, and the Forest of Dean. The total output for the whole of England in 1904 was over 161,000,000 tons, while Wales produced about 35,500,000 more.

The total for England and Wales was thus nearly 197,000,000 tons, giving a total for Great Britain of over 232,000,000 tons.

The Irish coalfields are small and little developed. The most important are those of Dungannon in Ulster, and of Kilkenny in Leinster. The output in 1903 was only 100,000 tons. About 175,000,000 tons are estimated to exist.

Total Coal Resources of Britain. The recent Royal Commission estimated that there existed reserves of coal amounting to nearly 101,750,000,000 tons in visible coalfields, and to over 39,000,000,000 tons in concealed coalfields. This vast amount, enough at the rate of 230,000,000 tons a year to last for six centuries, includes none more than 4,000 ft. below the surface, or more than three miles under the sea. The value of the estimated output is about £95,000,000 annually.

The quantity of British coal exported has for several years exceeded 40,000,000 tons. In 1904 it exceeded 46,000,000. This does not include bunkerage for consumption on board ship, which amounted in 1904 to over 17,000,000 tons, making a total of nearly 64,000,000 tons, or over 30 per cent. of the output. France, Germany, and Italy are the largest importers.

For a list and map of the British coalfields, see pages 987 and 988, and for the use to which the coal of each field is put, see the "Industry and Trade of Great Britain," in a later article.

Russian Coalfields. The coalfields of Russia are nearly twice as great in area as those of Britain; those of Spain are less than half as great as our own. Here, again, area is not the proper basis of calculation, for Germany, with less than one-tenth of the actual area of the Russian coalfields, is the third largest producer in the world.

The coalfields of Russia are found (1) in South-west Poland; (2) in the Donets basin, covering an area of over 10,000 sq. miles; (3) in Central Russia round Moscow; and (4) in the Urals. Beyond the confines of European Russia are the coalfields of the Caucasus and the Altai. The Moscow, Donets, and Polish coalfields are all developing rapidly. The present output of Russia is about 16,000,000 tons, valued at nearly £7,000,000.

Spanish, French, and Belgian Coalfields. Between Santander and Oviedo is the potentially rich coalfield of Asturias, with 60 workable seams of good quality. There are also rich deposits in Eastern Spain. The present output, however, is small, being under 3,000,000 tons, valued at less than £1,000,000.

The important Franco-Belgian coalfield stretches from near Aachen to Calais (210 miles), where the strata dip beneath the Channel, to reappear near Dover and in the Bristol coalfield. On this coalfield are the iron towns of Liège, Namur, and Mons in Belgium, the cotton town of Lille in France, and many smaller industrial towns in both countries. The total area is about 1,200 sq. miles, but the strata are in places interrupted by or buried beneath the chalk.

In Central France, on the flanks of the Central Plateau, are many small fields of which St. Etienne is the busiest centre. This also supplies the silk industry of Lyons.

The present output of France exceeds 32,000,000 tons, valued at £19,000,000. The Belgian output is 22,000,000 tons, valued at £13,000,000.

The Coalfields of Germany and Austria-Hungary. The Saar coalfield is the largest in Germany (900 sq. miles), supplying the rapidly growing industries of Alsace-Lorraine. The strata probably descend to 20,000 ft., so that the full resources can never be utilised.

The Westphalian or Ruhr valley coalfield extends from the Rhine at Duisburg and Ruhrort for about 40 miles up the Ruhr valley. The great iron towns of Essen and Barmen-Elberfeld are on the coalfield, which also exports coal by the Rhine.

The other important coalfields are in Saxony, on the flank of the Erz Gebirge, or Ore Mountains, and in Silesia, on the flanks of the Riesen Gebirge, and in the extreme south-east at the western end by the Polish field. The total output of Germany is about 130,000,000 tons, about half that of Britain, valued at £55,000,000.

In Austria-Hungary coal is found in Bohemia, Moravia, and Silesia, in the flanks of the Central European Highlands. There is practically no coal in the Alpine provinces, but some lignite is found in Styria. The output is about 40,000,000 tons, valued at £9,000,000.

In the other countries of Europe coal is unimportant.

The Coalfields of Asia. China probably possesses the largest and richest coalfields in the world. The province of Shansi, in Northern China, has seams of coal 40 ft. thick, and easily accessible. Iron is also abundant, and the whole region is destined to become a second and richer Pennsylvania The deposits are continued in the adjoining province of Honan. In the Yangtse basin of Central China, and especially in the Red Basin of Szechwan, coal is exposed in the gorges of the Yangtse and its affluents, needing only to be followed by adits, as in South Wales. There are also coalfields in Hunan and Kwangtung in Southern China, in Manchuria, and in Korea. Japan has coalfields in Kiushiu, Yezo and Formosa. In Tongking there are coal seams 70 ft. thick. Still further south coal is found in Borneo.

Coal is found in many parts of India, but most abundantly in Northern India. The most important coalfield at present worked is that of Raniganj (500 sq. miles), about 120 miles from Calcutta. The output of India is at present only 7,000,000 tons.

Australasian and African Coalfields. Important coalfields lie between the Great Dividing Range and the Pacific Ocean, in New South Wales and Queensland. Newcastle, at the mouth of the Hunter River, is the outlet for the mines of that district. At Brisbane, the capital of Queensland, says Professor Hull, quoting the famous Australian geologist Clarke, "steamers can load by lying literally at the mouth of the mines," for the coal seams are exposed close to the sea and are accessible by adits. Tasmania is also well provided with coal. In New Zealand North Island has considerable deposits of lignite, while South Island has both lignite and coal.

Africa is poorly provided with coal in comparison with the other continents. A little is found in Abyssinia and British East Africa, but the rich coalfields of the continent are south of the Zambezi, in British territory. Large deposits of good coal occur in Rhodesia, the Transvaal, and the Orange River Colony. Good bunker coal is obtained from Newcastle and Dundee in Natal, and there are also deposits in Eastern Cape Colony. If, as some geologists think, these are parts of a single great coalfield, the potential resources of South Africa are considerable.

Coalfields in the New World. Coal is very unequally distributed in the New World. In South America it occurs in parts of Venezuela, Southern Brazil, Uruguay, Argentina, including Southern Patagonia and Tierra del Fuego, Chile, and Peru, but not to any great extent. The output of Chile, though increasing, is not yet large. The coalfields of North America vie with those of Eastern Asia in extent and value.

Rich coalfields are worked in Nova Scotia in the east, and in Vancouver Island in the west of Canada, the Nanaimo mines of the latter yielding the only good coal of the Western Pacific shores. In the interior, coal occurs from Manitoba westwards, especially in the Rocky Mountains, but owing to the lack of communications and population, only a fraction is worked. The coalfield west of the Crow's Nest Pass, now reached by the railway, is said to be one of the most extensive deposits in the world. Unfortunately, Eastern Canada, the most densely-populated part, is destitute of coal, and imports much from the United States, Buffalo being the chief lake port.

Coal in the United States. The United States ranks first among the coal-producing countries of the world, with an output of 284,000,000 tons, valued at nearly £85,000,000. Coal is said to underlie about one-sixth of the country, but estimates of the total area of the coalfields vary considerably. Those of the late Professor Rogers made it about 197,000 sq. miles, but the later estimates of Professor Hitchcock raise it to nearly 230,000 sq. miles. Other estimates put it at a still higher figure. The figures given below are those of Professor Hitchcock. Bituminous coal is mined in twenty-five States, Pennsylvania, Illinois, Western Virginia, and Ohio coming first. Much coal is locally used, especially in the busy region round the Upper Ohio.

The coalfields of the United States are (1) the Appalachian field, extending from New York to Alabama, a distance of 900 miles, through the States of Pennsylvania, Maryland, West Virginia, Ohio, East Kentucky, Tennessee, Georgia, and Alabama. In West Virginia the thickness of coal is about 50 ft. The total area of the coalfield is over 63,000 sq. miles. The coal is often exposed in the deeply-cut mountain valleys, so that it can be easily and cheaply worked. The numerous rivers transport it cheaply to the towns and industrial centres. Its combination with iron in Western Pennsylvania has created the great iron industries which centre round Pittsburg. In this region, and especially at Connellsville, is made three-quarters of the coke of the United States, used chiefly in the pig iron industry. The output of Pennsylvania is about 82,000,000 tons of bituminous coal. New York ranks next to London as a coal market.

The Central Coal Basin, east of the Mississippi, in the States of Illinois, Indiana, and Western Kentucky, is over 51,000 sq. miles in extent, with a maximum of 30 ft. of coal. The northern or Michigan basin is small, under 7,000 sq. miles, with a maximum of 11 ft. of coal. West of the Mississippi is the vast West Central or Missouri coalfield, with an area of over 100,000 sq. miles, in the States extending from Iowa to Texas, and including parts of Nebraska, Missouri, Arkansas, and Indian Territory. Much of the Texas coal, however, is poor in quality. There is also coal in parts of the Rocky Mountains, and in parts of the Pacific coast.

A Vast Deposit of Anthracite. Pennsylvania also leads in the production of anthracite, turning out about 55,000,000 tons a year. The deposit area of anthracite, Susquehanna, Lehigh, and the Schuylkill valleys of Eastern Pennsylvania, is estimated at about 450 sq. miles. A species of anthracite, resembling graphite and very difficult of combustion, is found in the New England basin, estimated at 750 sq. miles in area. Small deposits are also found in Colorado and New Mexico. Lignite is abundant in the western part of the Central Plain, and round the Gulf of Mexico.

Most of the United States coal is absorbed by the home market, though increasing quantities are exported to Canada, the West Indies, Central and South America.

In Mexico coal is found in several parts, but at a height of from 2,000 to 4,000 ft. above the sea. There is also some coal in Central America and the West Indies.

The world's output of coal at the present time thus amounts to over 800,000,000 tons a year, valued at nearly £300,000,000.

Petroleum. Petroleum is a liquid mineral product, stored in subterranean reservoirs. These are generally reached by boring, but there are also "gushers," or free-flowing wells, yielding many thousands of gallons daily, much of which runs to waste before storage apparatus can be erected. The crude oil is usually carried in pipes to the centres from which it is distributed, refined, or unrefined, as the case may be, by pumping it into tank cars or tank steamers.

Petroleum is widely distributed. It is found in Germany, Galicia, Rumania, and on a vast scale in Southern Russia in Transcaucasia. The petroleum of the oil-fields of Burma is carried by pipes to Rangoon, for the Indian market. The line of deposits is continued in the islands of the Eastern Archipelago (Java, Sumatra, Borneo, the Philippines), near Sydney, in New South Wales, and in New Zealand. Africa has workable deposits in Algeria and Cape Colony. The oil-fields of North America vie with those of Russia. Those of South America (Peru, Venezuela, Argentina) are less considerable.

Baku, on the Caspian Sea, is the chief centre of the Russian oil industry, which in 1901 produced nearly 300,000,000 gallons. Political strife and insurrections have greatly injured it in the last year or two. Much of the output goes across the Caspian to Astrakhan and the Volga for the European markets. Some is distributed through Batum and Poti, on the Black Sea. The restriction on sending oil in bulk through the Suez Canal is now removed, and Port Said is the depôt for the Eastern market.

Petroleum in the New World. The first boring for petroleum in the United States was made in Pennsylvania in 1859. The product was refined round Pittsburg and Oil City. This region still leads in output, with 20,000 wells and several thousand miles of pipes leading to refining and exporting centres on the Great Lakes and the Atlantic coast. Ohio, Indiana, Texas, and California have increasingly important sources of supply. Fresh discoveries will doubtless be made. As lately as 1901 a very productive region was found at Beaumont, in Texas, less than 20 miles from the sea.

The distillation of petroleum is said to yield 200 different products which are widely used in the industrial arts. The lighter oils, known in the United States as kerosene, are used for lighting, the heavier (American paraffin) for heating and lubricating machinery. Oil fuel for steamers and trains, already used to some extent, has probably a great future. Other products, all highly inflammable, are naphtha, gasolene or petrol, benzene, benzoline, and rhigoline, the latter used to cause local anæsthesia by rapid evaporation. The residuum yields paraffin and vaseline. The former is used in making candles and to insulate electric wires. Ozokerit, a very similar substance of natural origin, found in Galicia and Utah, is put to the same uses.

British paraffin oil and paraffin wax are distilled from bituminous shale near Edinburgh. Similar shales are worked in New South Wales and Queensland.

Natural gas occurs in many parts of the United States, but is commercially important only in Western Pennsylvania and parts of Ohio and Indiana, where it is carried by pipes to the industrial centres. It has special advantages in glassmaking, which has become important in Western Pennsylvania.

Asphalt, used in street paving, can be obtained from petroleum, but its commercial sources are the natural deposits in Barbados, Trinidad, Venezuela, Algeria, the Swiss Jura (Val de Travers) and other parts of Europe.

Iron and Steel. Iron ranks next to coal in commercial importance. Directly or indirectly, it is used in nearly all industrial undertakings, so that the material condition of a country can be roughly estimated by the annual consumption of iron. In the United Kingdom and the United States, it amounts to about 300 lb. per head of the population, against less than 3 lb. in India. Iron is said to occur pure in Greenland, but elsewhere it is mixed with carbon, sulphur, phosphorus and other impurities. [See METALS.] The principal iron ores are (1) the black oxide or magnetic iron of Sweden, the Urals, Canada, and the United States; (2) the red or brown hæmatites of Northern Spain, Elba, France, Germany, and the British Isles. In England there are deposits 15, 30, or 60 ft. thick, in the Furness district. The purer carbonates of iron are known as spathic ore, the less pure as clay ironstone and blackband ores. The Eisenerz district of Styria is the chief source of spathic ore. Some spathic ores are rich in manganese, which plays an important part in the Bessemer process. [See below.] The clay and blackband ores are very common in Britain. The sulphides, or iron pyrites, are valuable only for the sulphur they contain, a minute percentage of sulphur being extremely injurious in iron.

The Supply of Iron. Iron is very widely distributed over the world, but the United States, the United Kingdom, and Spain, are the chief sources. The best ores are those of Canada, Lake Superior, Sweden, and Algeria. The chief iron fields of Britain are in the Scottish coalfield, on the Cumberland coalfield, including the Furness district of Lancashire, round the Tyne and Tees, including the Cleveland district of North Yorkshire, on the Yorkshire coalfield, especially round Sheffield, in many parts of the Central Plain, especially on the coalfields, and on the South Wales and Bristol coalfields.

In the United States the Northern Appalachian region (Pennsylvania, New York) has in recent years been passed by the Lake Superior region (Minnesota, Michigan) and by the Southern Appalachian (Birmingham, Ala.).

Iron occurs either at the surface or at considerable depths. The Bell Island mines of Newfoundland are really an open quarry of red hæmatite. Some of the famous iron ores of Lake Superior can be extracted by steam shovels, the daily output of each shovel being from 1,500 to 2,000 tons.

Iron enters into commerce as pig iron, cast iron, wrought iron, and steel.

Iron Smelting. To remove impurities iron must be smelted. Before the use of coal, the fuel was charcoal, but only very pure ores could be used. The iron industry was then confined to forested districts such as the Forest of Dean, in this country, or the Weald, which was gradually deforested by the ironworkers. The black oxide occurs in rocks in which coal is very seldom found, and these ores are still smelted with charcoal in Sweden and Russia, both forest countries. The process is much dearer, but a much better result is obtained. With the introduction of coal fuel the iron manufacture shifted to the coalfields. In our own country coal and iron generally occur together. This is one of our great commercial advantages. Where they do not occur together it is more economical to carry the ore to the fuel, for the equivalent of two tons of coal is needed to turn out one ton of steel. This is profitable only where water transport is available, as in the case of Lake

Superior, Sweden, and Northern Spain. Where long railway freights would be incurred, as with the rich iron deposits of the Rockies, iron, however abundant, is commercially of little value.

Coke, which is relatively free from sulphur, petroleum, or natural gas, is also used in iron smelting.

To extract iron from the ore the latter is smelted, or melted, by intense heat, in blast furnaces with forced draught. The largest furnaces in this country are round Middlesbrough, the centre of the Cleveland district.

Where coal, iron, and limestone occur together a district is ideally situated for iron smelting. This is the case in the coalfields of the Pennines, in this country, and in the Birmingham district of the Southern Appalachians.

The World's Production of Iron. The total quantity of ore to-day extracted exceeds 90,000,000 tons, valued at over £26,000,000. The United States turn out nearly 31,000,000 tons, or over one-third; Germany (with Luxemburg), 17,500,000 tons, or nearly one-fifth; and the United Kingdom, over 13,000,000, or one-seventh. Spain produces 8,000,000 tons, Russia and France about 5,000,000 tons each, and Sweden and Austria-Hungary over 3,000,000 tons.

The world's production of pig iron is about 50,000,000 tons, the United States leading with 23,000,000 tons in 1905, or more than one-third. In 1905 Britain turned out 9,593,000 tons. Half a century ago the United States produced only half a million tons, and this country only 2,225,000 tons.

Wrought iron, which is malleable, ductile, and very flexible, is made by stirring or "puddling" molten pig iron in contact with the air to burn out the carbon.

Steel. Steel is a form of iron in which the small proportion of carbon required seems to enter into chemical combination with the iron instead of being present as an impurity. Steel is harder and stronger than iron and finer in grain.

For ordinary purposes steel is made by one of three processes—the Bessemer process, the Siemens-Martin, or open-hearth process, and the basic process [see METALS]. Where phosphorus is present in the ore the basic process is used, lime being introduced to combine with the phosphorus. This discovery allows the Cleveland ores to be made into steel, and has greatly increased the prosperity of Middlesbrough.

The World's Output of Steel. The world's output of steel exceeds 33,000,000 tons, of which over 14,000,000 tons are made in the United States, over 7,000,000 tons in Germany, and nearly 5,000,000 tons in this country. In the United States the steel industry, formerly carried on almost exclusively at Pittsburg, is now extending north to the southern shores of Lakes Erie and Michigan, where the ores of Lake Superior meet the coal of Ohio and Illinois, and to the Birmingham region of the Southern Appalachians.

Forty years ago, when iron rails were used, only light engines of 25 to 35 tons could be used, and traffic was proportionately slow. Modern engines, running on steel rails, are three or four times as heavy. Steam boilers resist four times more pressure than the old iron ones, so that speed is accelerated while fuel is economised. This has led to an enormous development of railway and steamer traffic, and, generally speaking, to an all-round cheapening of commodities. Great engineering works, such as the Forth Bridge or the bridge across the Zambezi gorge, have been rendered possible. Steel is even replacing timber in the framework of modern buildings, especially in the sky-scrapers of the United States.

Gold and Silver. Gold and silver play an important part in the commerce of the world by serving as the basis of the currency. They have also many uses in the industrial and decorative arts. Both gold and silver are very widely distributed, but many deposits would not pay working expenses. Gold is found in quartz or other rock veins, either pure or in combination. The rock has to be mined, crushed, and chemically treated [see MINING and METALS]. In many regions gold-bearing rocks have weathered, and gold is carried down by the streams, from whose sediment it can be extracted by washing, the lighter matters draining away, and the heavier gold remaining. Roughly done, this process (placer mining) is wasteful, and it is now generally carried out on a large scale by hydraulic apparatus and the use of mercury, which forms an amalgam with the gold.

The discovery of rich placer deposits in the Californian Sierras in 1848 led to a "gold rush." Similar outbreaks of "gold fever" followed the discoveries of placer gold in Australia in the 'fifties, and in the Klondyke in the 'nineties.

The world's output of gold has been increased in the last half-century by these and other discoveries, and by improved methods of extraction. In 1905 it was estimated at 541 tons, valued at £75,000,000. The Transvaal, where the richest auriferous district is the Rand, near Johannesburg, leads with an output valued at about £20,000,000. The United States produce nearly £16,000,000; Australia, £15,000,000; and Russia less than £5,000,000. Canada, Mexico, and India rank next. The British import of bullion exceeds £21,000,000, three-fifths of which comes from South Africa and one-sixth from Australia.

Most of the civilised countries of the world take gold as the standard of value and the basis of the currency. Owing to its extreme softness, it is mixed with silver, iron, copper, or other alloy to give it sufficient hardness. Gold is also largely used in the decorative arts, and is put to some industrial purposes (photography, dentistry). Gold leaf is made by beating out a given quantity of gold till its thickness is inappreciable.

Silver. Silver is generally found in combination with other elements, and very commonly with lead. The whole of the Pacific of North America is argentiferous, Mexico, the United States, and Bolivia leading as silver-producing countries. Mexico produces over 60,000,000 oz., or somewhat less than 2,000 tons. The United States exceeds 55,000,000 oz. Bolivia and Australia both exceed 10,000,000 oz., or 300 tons. The total output of the world is over 170,000,000 oz., valued at over £20,000,000. The value of silver has fallen rapidly in recent years, being less than 1s. 10d. an ounce in 1902. It has since gradually risen, and stands to-day at about 2s. 6d. an ounce.

Silver forms part of the currency of gold standard countries, and the entire currency of many others. It is used in making plate and jewellery, in other decorative arts, in photography [see PHOTOGRAPHY], etc., and also for electro-plating [see ELECTRICITY and METALS].

Copper. Copper is, after silver, the best conductor of electricity, while it is much cheaper. The demand has therefore increased enormously in recent years. Copper is found either pure, as at Lake Superior and Bolivia, or in ores, the smelting of which presents considerable difficulty, and tends to be carried on at a few noted centres. In the 'sixties, Chile was the main source of the world's copper supply, but it is now surpassed by the United States, which turns out half the world's product of 770,000 tons (1906), valued at about £66,000,000. The most important deposits, besides those of Lake Superior, are in the Rockies. These are continued in Mexico and in the Andean countries—Chile, Peru, Argentina, Bolivia. In Europe the chief mines are in the Iberian Peninsula, especially in the Rio Tinto, and in the Harz. Japan and Australia are also copper producing countries. The chief smelting centres in this country are at Swansea, Widnes, and Glasgow.

Copper is chiefly used for electrical apparatus, for sheathing ship plates, and in the manufacture of brass, bronze, and bell-metal. The increasing demand is leading to a rise of prices, and rumours of a future copper famine.

Lead. Lead is seldom found pure. It generally occurs in the form of galena, which contains a proportion of silver. In Europe, Spain and Germany are the chief sources of supply. Australia yields about one-tenth of the world's output, which amounts to about 870,000 tons, valued at over £11,000,000. In the New World, lead is found in the Rockies, including Mexico, and in Peru and Chile in South America. It is in increasing demand for plumbing, roofing, the manufacture of shot and type metal, and for the manufacture of solder, pewter, Britannia metal, etc. Red and white lead are largely used in the manufacture of paints. The United Kingdom and the United States take more than half of the world's supply of lead, the output of Mexico going to the latter, that of Spain to the former. Great Britain has the largest import and export trade in lead in the world.

Mercury. Mercury, or quicksilver, is a liquid metal, used in making scientific instruments, such as the thermometer and barometer, in gold-mining, medicine, etc. The most famous mines in Europe are those of Almaden, in the Sierra Morena (Spain), Idria, in Carniola (Austria-Hungary), and Northern Italy. In California are the rich mines of New Almaden. Large quantities of mercury are exported from San Francisco to the mines of Mexico and Central and South America.

Tin and Zinc. Tin, though widely distributed, seldom occurs in paying quantities. The mines of Cornwall, the richest in Europe, no longer supply the demands of the home market. At present the chief sources of supply are the Malay Peninsula, and the islands of Banka and Billiton in the Dutch East Indies. Tin also occurs in Australia, and is exported in some quantity from Tasmania. Bolivia is the chief exporting country in the New World. Tin is chiefly used to coat thin sheets of iron (tinplate), from which tinware is made. The South Wales coalfield is largely engaged in the tinplate trade. Tin is also used in making bronze, pewter, and Britannia metal. Zinc is found in various parts of the United Kingdom, but Prussia and Belgium are the chief sources in Europe. In the United States it is found in the States of Kansas and Missouri. It is largely used in making galvanised iron, so extensively used for roofs.

Other Metals and Minerals. The other metals of commercial value are aluminium, obtained by electric processes from bauxite and cryolite. [See METALS.] Aluminium works are commonly near falls (Niagara, the Swiss valleys, the Falls of Foyers in Inverness, etc.), which supply the needful power. For antimony, arsenic, bismuth, chromium, cobalt, manganese, nickel, and platinum, and their uses [see METALS].

Many other commodities belonging to this class might be mentioned if space permitted. Sulphur, used in making gunpowder and matches, in the vulcanisation of india-rubber, and for many other purposes, is obtained either from volcanic districts, or from iron pyrites. Plumbago (graphite, blacklead) is chiefly obtained from Ceylon. Nitrate of soda, a valuable agricultural fertiliser, is worked in the deserts of Northern Chile. Salt, one of the most valuable articles of diet, is found in many parts of the world, either as rock salt, or brine springs. It is also obtained by evaporating sea water [see article on Condiments in FOOD SUPPLY.]

Marble is the most valuable of many building stones. Lithographic stones are obtained from Bohemia. Kaolin, a decomposed granite which derives its name from the Kaoling Mountains of the Chinese province of Kiang-si, is used in making pottery and paper. It is found in Cornwall, France, Germany, and the United States [see EARTHENWARE].

Precious Stones. The most valuable of precious stones is the diamond. Nearly the whole of the world's supply comes from South Africa. Brazil supplies only a fraction, and those of inferior quality. Pearls and mother-of-pearl are obtained from the Persian Gulf, Ceylon, the seas round Australia, and Venezuela. Rubies come chiefly from Burma and Siam. Sapphires are exported from Ceylon, Kashmir, Burma, and Queensland. Opals come from Hungary, Mexico, Colorado, New South Wales, and Queensland. Coral, produced by the coral polyp, is fished in various parts of the Mediterranean.

APPLIED BOTANY
8

RUBBER AND GUTTA PERCHA
continued from page 5203

THE recovery of rubber is a problem to the solution of which much thought and research have been devoted, and it cannot be said that it is yet adequately solved. The nature of the reaction which occurs between the prepared caoutchouc and sulphur during vulcanisation renders the elimination of the combined sulphur and the reconstruction of the rubber hydrocarbon on a practical basis, which would be the ideal process, extremely improbable, if not impossible. Since this has been recognised, efforts have been directed to the removal of free sulphur and other ingredients, after which the recovered rubber is again worked up, either by itself or with some compounding material, such as fresh rubber.

The Waste Rubber Industry. The large annual consumption of rubber places huge quantities of old or waste rubber at the disposal of the manufacturer. Disused rubber shoes, large quantities of which are received from Russia, form one of the principal sources of raw material; old cycle tyres, and waste cuttings of vulcanised sheet rubber are also largely utilised. To a less extent, too, mechanical goods are employed, such as old hose, belts, and packing. Reclaiming waste rubber is quite a separate branch of the rubber industry to which many large firms devote themselves entirely. They usually have their own special methods of treating the waste material; many innovations and improvements in the processes are, however, constantly being brought out. There are two general methods in use—namely, one which is entirely mechanical, and the other a chemical treatment. Reclaiming rubber was first practised in the United States, where the process consisted merely of boiling the waste vulcanised rubber after it had been reduced to a powder, and then running it into sheets. The general lines upon which operations are now conducted are as follows: The raw material is first carefully graded, according to the quality of the rubber and the extent of oxidation it has undergone through use and exposure. Foreign substances, such as iron, brass, leather, textures, etc., are then removed as far as possible by mechanical means. The material is then ground and treated chemically for the removal of sulphur and fibres.

The usual agents employed to effect this are either acids or caustic alkalies. Neutral sulphite solutions have also been introduced for this purpose. The rubber is then well washed with water and dried, after which it is kneaded on heavy mixing rollers where additions of oil, paraffin, or naphtha are frequently made in order to render it plastic and cohesive, and amenable to treatment on the calenders by which it is rolled into sheets like unvulcanised rubber. The quality of the reclaimed rubber will naturally depend upon that of the raw material employed.

Uses for Reclaimed Rubber. Reclaimed rubber is used chiefly for soles of shoes and for compounding with unvulcanised caoutchouc. The mechanical process, which is not used to the extent of the above chemical method, consists of disintegrating the waste rubber, when fragments of iron are removed by magnets, and textile fibres blown out by treatment in a special apparatus. The powdered rubber is then strongly heated and drawn out into sheets.

Reclaiming Rubber by Means of Solvents. Non-volatile solvents have been found more applicable for the recovery of rubber than volatile solvents. Those principally employed are aniline, toluidine, and phenol, heavy oils, and tar, the chief obstacle encountered being the slight solubility of vulcanised rubber. The method of reclaiming with phenol consists mainly of extracting the finely-powdered waste rubber under reduced pressure. After removal of the free sulphur and separation of the reclaimed rubber, the phenol is recovered by distillation. In another process coal-tar bases, such as aniline, are employed for dissolving the rubber, which is afterwards thrown out of solution in the form of a tough mass by the addition of acid.

The making of rubber substitutes is another question which has long claimed the attention of rubber chemists and manufacturers. Owing to the high cost of rubber, extensive trials have been made to provide an artificial substitute which would have similar, or identical, properties to the genuine article. France achieved the greatest success in this direction and the first rubber substitute emanated from that country, whence products of this description have derived their name of "factice," which is a generic term for all artificial rubber compounds made with vegetable oils. The oil, which is either linseed, rape seed, or cotton-seed oil, first undergoes an oxidation process, and is then either treated with chloride of sulphur or mixed with sulphur and heated.

Three Kinds of Rubber Substitutes. There are three kinds of substitutes — white, brown, and black. Their value lies, when used in moderation, in lowering the cost of the material without deteriorating its quality to any appreciable extent, and for this purpose they possess certain advantages over mineral adulterants and bituminous products. Besides sulphurised oils, many other substances of most diverse natures, including resins, glues, asphalt, and cellulose, have been tried for producing a good substitute. Two or three compositions may be worth mentioning. Blandite, invented by Dr. Blandy, is an artificial indiarubber of fair elasticity; it is vulcanised like the ordinary rubber, and can be moulded. Its constituents are oxidised linseed oil to which a 10 per cent. solution of chloride of sulphur in carbon bisulphide is added with gentle heat: one part of the oil is then mixed with three parts of Trinidad asphalt, the whole being gradually liquefied by heating and stirring, after which it is run into sheets.

Fenton's artificial rubber is a product patented by F. Fenton and manufactured from linseed or similar oils, which are mixed with tar or pitch and submitted to the action of dilute nitric acid, until the whole coagulates into a tough elastic mass. Further treatments with solutions of nitrates are recommended, and after vulcanising, "Fenton rubber" is said to resist a temperature of 320° F. without its elasticity being impaired.

Parkesine, Rubberite, and Textiloid. *Parkesine* is a proofing and moulding compound. It is prepared by treating cotton rags with sulphuric acid, the acid being subsequently neutralised with carbonate of soda. After being washed and dried the product is reduced to powder, and then may be used for compounding with fresh rubber, or as a proofing compound mixed with 10 to 20 per cent. of linseed oil. *Rubberite*, invented by H. C. B. Graves, consists largely of Trinidad asphalt and oxidised oil, with small proportions of vaseline, sulphur, and chloride of sulphur. In colour, elasticity, and durability, it is said to resemble the higher grades of rubber. *Textiloid*, another proofing substitute, is a mixture of resinoline, cellulose, and camphor; it is odourless, practically non-inflammable and very elastic.

There are a large number of compounds constituted in a similar way to the above with slight alterations and the introduction of certain specific substances which are intended to produce products having the essential characteristics of rubber.

Special Uses for India-rubber. Besides the large number of purposes to which india-rubber is put, and which readily occur to the mind, there are one or two others less well known in which it is none the less valuable. As a floor covering it has been used for many years with excellent results, and its wearing properties are remarkable. Rubber tiling has been known, when laid in juxtaposition with flagstones, to require cutting down to the level of the latter after several years' wear. Rubber tiling for offices is laid in a variety of patterns, and as it always presents a very good surface it is easily cleaned. Figure **14** shows the method in which the tiling is laid.

A compounded floor covering, known as kamptulicon, is made from vegetable fibrous materials, which are ground into a coarse powder, then mixed with india-rubber, and treated with a cheap solvent: other substances may also be incorporated, such as reclaimed rubber, ground cork, and cheap grades of gutta percha.

Cements of great variety are made from rubber, being largely used in the leather industry, and also for cycle tyres. The rubber is dissolved in solvents, the nature of which is determined by the purpose for which the cement is required, all manufacturers having their own special formulæ.

Hard Rubber. The invention of hard rubber, vulcanite, or ebonite is due to Goodyear, although many investigators have studied the product, with the result that improved methods of manufacture, producing more satisfactory results, have since been introduced. Its manufacture is, on the whole, based on the same lines as for the production of soft rubber goods, the essential difference lying in the increased amount of sulphur used. The raw rubber is washed, dried, masticated, and compounded with suitable ingredients. The sulphur added sometimes amounts to 60 per cent.; more than 50 per cent., however, is inclined to make the product brittle. The quantity of sulphur present also regulates the degree of hardness, which increases proportionally according to the amount of sulphur added.

Sulphide is sometimes substituted for the sulphur, and other compounding materials are also frequently incorporated on the mixing rollers to impart certain characteristics in colour, texture, or flexibility. Those chiefly employed are whiting, zinc white, magnesia, resins, and sulphides of mercury and antimony. Great care must be taken that the materials be thoroughly dry, because if any moisture be enclosed during the mixing, steam would be evolved in the subsequent vulcanising operations, and this would render the goods porous, a very objectionable trait.

Vulcanising Hard Rubber. The prepared material is drawn out into sheets in a similar manner to ordinary rubber, and from these articles are accordingly fashioned. Metal or textile insertions are rarely used, as there is very little call for them. The goods are usually vulcanised in moulds; tubes in the same way as soft rubber tubing—namely, on their metal core, and bound up with cloth. The boilers and presses employed for vulcanising hard rubber goods are the same as for soft rubber, but a considerably higher temperature is required. The process is usually started at about 250° F., and is gradually raised to 300°, 320°, or even 330° F. The time, of course, depends largely upon the dimensions of the articles, and the composition of the rubber, and varies from six or seven hours to as long as ten or twelve hours.

Characteristics and Uses of Hard Rubber. The physical properties of hard rubber are quite at variance with those of soft vulcanised rubber. It is of a black colour, without smell, and may be compared to horn, hard wood, or even ivory in texture. Ordinary atmospheric influences do not affect it: it does not oxidise nor change in cold water, but in boiling water it softens somewhat, so that it can be bent. It is a non-conductor of electricity, and is not dissolved nor influenced by the ordinary solvents of rubber; acids also have little action on it. On being heated to about 400° F., ebonite carbonises without passing through any intermediate melting stage.

As this material can be easily worked with all kinds of cutting tools and also takes a fine polish, it is much appreciated for the manufacture of fancy goods, as well as being largely employed for technical purposes. It is used for the production of a great number of small articles, ornaments, and imitation jet, and when given a specially fine polish it serves to imitate onyx. To assist polishing operations, which are usually done on a lathe or by polishing discs, the moulds in which the compounded rubber is vulcanised are made of glass, or if of iron they are lined with tinfoil. One of the most important uses for which hard rubber is indispensable is the manufacture of certain parts of electrical machines, insulating appliances, and accumulator cases. For photographers' developing dishes, tubes, taps, and other adjuncts for chemical laboratories, hard-rubber is specially serviceable.

Semi-hard Rubber. An intermediate product, called *semi-hard rubber*, is manufactured for certain purposes where greater elasticity or flexibility than hard rubber possesses is required. More sulphur, however, is employed than for soft rubber goods, and vulcanisation is carried out at a higher temperature, and for a longer period, but care must be taken not to go too far in these three particulars, otherwise hard rubber would be produced; in fact, they must be moderated according to the exact degree of hard or soft rubber which it is desired to produce. This kind of rubber is used for lining acid vats, for making large cylinder covers, and for many other purposes of a technical nature.

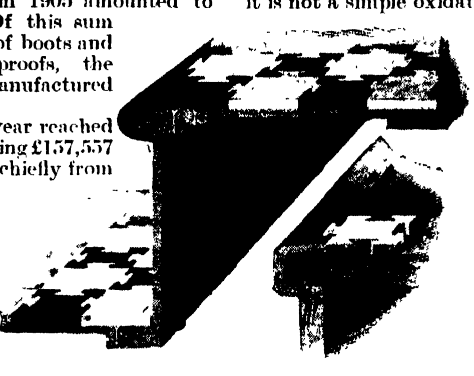
Another branch of the hard-rubber industry is the preparation of unvulcanised caoutchouc for dentists' purposes. The rubber is specially compounded to produce vulcanite of the desired shade and texture; it is then sold to the dentist, by whom it is cured and finished.

For the decoration of articles made of hard rubber, pigments mixed with shellac are applied by brush. A hot plate is then forcibly pressed against the surface, so that the colour becomes inseparably fixed.

Substitutes for Hard Rubber. Many substitutes for hard-rubber, made from cellulose, gums, and various other substances of animal, vegetable, and mineral origin, have been devised, but none approach the original article. To mention two: (1) *Kiel compounds*, which are compositions of india-rubber, sulphur, pumicestone, oil and beeswax. When vulcanised, this compound withstands immense cold; it resists acid, is an excellent insulating material, and is also cheap; it can, moreover, be worked with greater ease than hard rubber. (2) *Vulcanised fibre*, which is manufactured from cotton paper pulp that is dissolved chemically, and solidified under great pressure. It is made in two forms—hard and flexible; the hard fibre is very tough, and strong like horn. In dry places it can be used as an insulator, and is not affected by oils or fats.

Exports and Imports of Rubber Goods. The total exports of manufactured rubber goods of both British and foreign make from the United Kingdom in 1905 amounted to the value of £1,865,642. Of this sum £249,212 represent the value of boots and shoes, and £227,893 waterproofs, the balance being other sorts of manufactured rubber articles.

The imports for the same year reached the figure of £846,400, comprising £157,557 for boots and shoes, received chiefly from Germany and the United States, and £5,681 for waterproofs, leaving £683,162 for other kinds of goods.



14. METHOD OF LAYING RUBBER TILING
(A. L. Gibson & Co., London)

The Chemistry of India-rubber. The colloidal nature of india-rubber occasions great difficulties in its chemical investigation, since, unlike bodies of a crystalloid character, compounds belonging to this class have no definite characteristics as melting points, boiling points, and definite solubilities, but pass gradually from one state to another. Accordingly, their separation from mixtures and their purification is attended with great difficulties. Being derived from a variety of trees, shrubs, and vines, it is not surprising that the chemical composition of commercial rubbers varies to a considerable extent. Impurities, such as sand, vegetable matter, fibre, etc., are removed by washing, but the water also carries away certain sugars from the rubber, although these are present only in small quantities, rarely exceeding 0·5 per cent. After the washing process the rubber is by no means a chemically pure product; it is, however, regarded as technically pure. It contains certain oily and resinous substances which can be extracted by solvents such as alcohol or acetone. The quantity of these resinous substances ranges from 1 per cent. to about 40 per cent. Their nature also varies with different brands, from an oily extract through different degrees of viscosity to resins resembling colophony; sometimes they are even of a white, powdery nature. Small quantities of albuminous matters also occur in crude rubber, especially when the latex has been coagulated by heat, by chemicals, or by drying. If the latex were to be coagulated by centrifugal means, these substances would be almost completely eliminated. Exact information regarding the amount of these albuminous substances in rubber is wanting, but from investigations on the latex it is assumed that they would amount to about 5 per cent. in dry rubber. Their removal on a commercial scale is practically impossible. The elementary composition of india-rubber, deducted from the investigations of many chemists prior to 1888, is $C_{10}H_{16}$.

Impurities of Crude Rubber. Of recent years further researches have revealed the presence of an insoluble constituent in rubber, and this subject has been carefully investigated by C. O. Weber. He found that this insoluble body possessed different physical properties to india-rubber, as it was not sticky, nor adhesive, though very tough when dry; it was further only moderately distensible. This body having been found to contain a considerable amount of oxygen, it is inferred from its chemical composition by this investigator that it forms a link between the india-rubber hydrocarbon and the complex carbohydrates (sugars) which are assumed to be the raw material from which the plant produces caoutchouc. That it is not a simple oxidation product of india-rubber is inferred from the elementary analysis of oxidised rubber, or Spiller's resin, to which it does not entirely conform. All rubbers appear to contain this body, but as the quantities are generally very small its presence is of much more interest scientifically than commercially, although it is suggested that certain irregularities observed in the vulcanisation process may be due to the presence of this insoluble constituent.

There is one other impurity always present in rubber, and that is a small percentage of mineral matter, generally described as ash. The amount is very equable for all commercial brands of india-rubber and is generally below 1 per cent., though some kinds contain as much as 2½ per cent. It is hardly possible as yet to assign the origin of a rubber from the constitution of its ash, but it is stated that lime predominates in Para rubber, ferrous salts in African rubbers, and magnesia appears to be a characteristic of Ceara rubber.

Synthetical Rubber. It has long been known that caoutchouc could be produced synthetically, because Professor Tilden stated, before the British Association in 1882, that it had been prepared from isoprene. The hydrocarbon isoprene, besides being one of the results of the dry distillation of caoutchouc, can also be separated from turpentine, colza oil, linseed oil, and castor oil. By allowing one part of isoprene to stand in contact with 15 parts of hydrochloric acid, then diluting with water and evaporating, a solid residue, which has analogous properties with india-rubber is obtained. The isoprene may also be exposed to light for a few months, when the formerly colourless liquid is converted into a thick syrup containing yellow flakes or lumps of rubberlike substance, which have been pronounced by scientists to be synthetically produced india-rubber. As considerable time is required, and the price of the raw materials would have to be low, the cost of *synthetical rubber* is naturally high, being from 200 to 300 times as great as natural rubber. Further, it is quite possible that the cost of producing the latter may be reduced in the future, so that there is no present prospect of the synthetical article having more than a scientific importance, at any rate for some time; and since the first announcement that it could be produced synthetically little advance has been made in the direction of the reduction of its cost.

Destructive Distillation of India-rubber. When pure india-rubber is subjected to destructive distillation three definite compounds can be isolated from the distillate—namely, isoprene, boiling from 98° to 100° F.; caoutchene, boiling at 338° F., and heveene, with a boiling point of 600° F. All these bodies have the same percentage composition as india-rubber (polyprene), but investigations indicate that they do not exist as such in india-rubber; but upon distillation a change is effected in the structure of the hydrocarbon with the formation of the three above-mentioned bodies, and, as previously stated, india-rubber may be formed by the polymerisation of isoprene under suitable conditions, although certain terpene compounds are produced from it at the same time to a considerable extent.

Dipentene, or caoutchene, is the chief product of the dry distillation of india-rubber; it may also be obtained in a variety of ways from certain terpenes or their derivatives. After heveene, the distillate consists of hydrocarbons boiling at a temperature over 600° F. Their percentage composition, however, still corresponds to that of india-rubber, and the amount of carbon remaining behind is so extremely small as to suggest that it arises from albuminous and other impurities. The quantities in which these products are produced vary according to the way in which distillation is carried out, but their respective yields are approximately as follows: isoprene, 5 per cent. to 6 per cent.; dipentene, 40 per cent. to 46 per cent.; heveene, 12 per cent. to 17 per cent.; polyterpenes, 26 per cent. to 38 per cent.; carbon residue, 2 per cent.; mineral impurities and water, 2 per cent. Little is known regarding the actual changes which take place during distillation. Whether the india-rubber molecule splits up at a given point with the formation of one or all of the above bodies, or the process is gradual still requires investigation, and probably much could be learnt from a close examination of the changes that take place during distillation. Different brands of rubber soften and liquefy at different temperatures, but they all yield the same series of products on being subjected to dry distillation.

Chemical Reactions. India-rubber is a colloidal substance, which in chemical indifference almost rivals the solid paraffins. The action of the halogens upon caoutchouc dissolved in chloroform is interesting. Chlorine acts very energetically, forming an addition and substitution product, the constitution of which agrees with the formula $C_{10}H_{14}Cl_8$. With bromine the action is less violent, a very indifferent product, corresponding to the formula $C_{10}H_{16}Br_4$, being formed. Investigations upon this compound have contributed considerably to the knowledge of the composition of india-rubber. On the addition of iodine to a solution of caoutchouc in chloroform, an addition product, [illegible]$_{10}H_{16}I_3$, is formed, but only very slowly. Similarly with the halogen acids, hydrochloric acid has the strongest action, forming the dihydrochloride from which the monohydrochloride is formed by hydrochloric acid being split off. Hydrobromic acid has a like action, but somewhat slower, while hydriodic acid has apparently no action. Sulphuric acid chars and oxidises india-rubber, but nothing is known regarding the constitution of the resultant products. Nitric acid has a very vigorous action upon india-rubber, a yellow body being first formed, which subsequently decomposes into nitrogen, oxalic acid and a product of the character of fat. Nitrous acid, in the absence of water, forms a compound corresponding to the formula $C_{10}S_{16}N_2O_3$, apparently polyprene nitrosite; upon the action of this acid a method of determining the value of crude rubber is based. The influence of oxidising agents upon india-rubber has never been systematically studied. Spiller isolated a product containing 27·5 per cent. of oxygen, and the substance known as Spiller's resin is a form of oxidised india-rubber.

What Occurs during Vulcanisation. The action of sulphur upon india-rubber—that is to say, the process of vulcanisation, has been investigated by a large number of chemists. Burghardt and Payen have regarded the reaction as one of substitution of sulphur for hydrogen. Donath has expressed the opinion that the vulcanisation process is one of molecular aggregation, somewhat comparable to metallic alloys, rather than the result of chemical combination. The reaction taking place when india-rubber is treated with a solution of chloride of sulphur has been made the subject of research by J. Minder, who presents the view that the solvent has a softening effect upon the rubber, which then absorbs the sulphur. Some maintain that substitution of sulphur for hydrogen takes place, the hydrogen going off in the form of hydrochloric acid; others that the chlorine effects vulcanisation. Weber has given a large amount of attention to the subject of vulcanisation, and states that before an exact knowledge of the process is acquired, elucidation of the colloidal state of rubber from a chemical point of view is necessary. Colloids are capable of being converted into what is known as the *pectous* condition. In this state they are much more indifferent chemically and physically. The change is brought about by various means according to the nature of the colloid—thus, on heating albumen with water it coagulates, or pectisation takes place. This state, which colloidal matter can be made to assume, plays an important part in the vulcanisation of rubber.

The Theory of Vulcanisation. It has been conclusively demonstrated by Weber, from an exhaustive series of experiments carried out on Para and other brands of rubber, that chemical combination does take place between the sulphur and caoutchouc with the formation of polyprene sulphide. As there is practically no evolution of sulphuretted hydrogen during the vulcanisation process, this must be regarded as an addition product and not one of substitution, in which sulphur takes the place of hydrogen. It was found, however, that the insoluble constituent of rubber (which does not exceed 5 per cent. of the technical product) when heated with sulphur does give off a considerable amount of sulphuretted hydrogen, due to the formation of a *substitution* product. The combination of sulphur with polyprene does not apparently take place in definite stages, the extent of combination being determined by time, temperature, and the amount of sulphur present. Experiments with hard rubber, however, showed that a definite amount of sulphur—namely, about 32 per cent., enters into combination, even when a considerable excess over this figure has been incorporated. Then, on continuing the vulcanising process, more sulphur was made to combine, but with evolution of sulphuretted hydrogen, showing that one of substitution was taking place. From this it is concluded that 32 per cent. of sulphur is the upper limit for the formation of addition products, and corresponds with polyprene disulphide with a formula of $C_{10}H_{16}S_2$. No exact data being obtainable regarding the lower limit for the formation of sulphur addition products, the amount of sulphur necessary for producing a well-cured rubber may be taken as a guide; this is from 2 per cent. to 2½ per cent., and it is extraordinary to find that this agrees fairly well with the formula $C_{100}H_{160}S$., which would contain 2·35 per cent. of sulphur. From this, Weber concludes that "the process of vulcanisation consists in the formation of a continuous series of addition products of polyprene and sulphur, with probably a polyprene sulphide, $C_{100}H_{160}S$, as the lower, and $C_{100}H_{160}S_{20}$ as the upper limit of the series. Physically, this series is characterised by the decrease of distensibility and the increase of rigidity from the lower to the upper limit, which term of the above series—which degree of vulcanisation is produced—is in every case only a function of temperature, time, and proportion of sulphur present."

Physical Characteristics of Rubber. When rubber is worked for a considerable time on the rollers, it becomes *fatigued*, although it will return to its original state to a great extent on keeping. In the fatigued condition it requires more sulphur for vulcanisation; the resultant product does not differ chemically, but its physical aspect is changed. Accordingly, to again quote Weber, "the physical state of the india-rubber colloid while under vulcanisation largely determines the physical constants of the vulcanisation product." This has an important bearing upon the reclaiming of rubber.

Researches upon vulcanisation with chloride of sulphur have proved that addition products are formed analogous to those obtained by vulcanisation with sulphur. The upper limit of the chlorosulphides, as they are termed, is a compound corresponding to the formula $C_{240}H_{348}S_{48}Cl_{48}$, and the lower limit $C_{240}H_{848}S_2Cl_2$. The chemical properties of these chlorosulphides are not affected by the strength of the solution nor by the nature of the solvent in which they are formed, but both these factors have a considerable effect upon their physical characteristics, and this affords a clue to many perplexing facts observed in the cold vulcanisation process.

Cause of "Blooming." In course of time, vulcanised rubber becomes covered with a fine, greyish deposit, sulphur eventually crystallising on the surface. This is technically known as *blooming* or *sulphuring up*, and microscopical examination has shown that the excess of sulphur is distributed throughout the vulcanised rubber in extremely minute globules. In time, crystallisation of the sulphur at the surface takes place, and spreads from globule to globule. The only way of prevention would be to induce crystallisation of the excess of sulphur in the centre of the rubber. It is curious that sulphuring up is unknown in ebonite, although it frequently contains 15 per cent. of free sulphur; it is assumed, therefore, that a state of solid solution exists between the polyprene sulphide and the sulphur in this material.

Further particulars regarding the chemical characteristics of india-rubber, the explanation of its indifference to the sulphur in the cold, and the extraordinary vigour with which it is attacked by chloride of sulphur, the action of chlorine in promoting the "cold cure," etc., are detailed in Weber's "Chemistry of India-rubber."

Valuation of Rubber. The quality of crude rubber is more frequently judged from its appearance, consistency, and the application of a few ready physical tests, for which considerable experience is required, than by chemical analysis. The chief determinations made in a chemical examination are loss on washing, the amount of oily and resinous substances, and the percentage of oxygen combined with the rubber and ash. The testing of manufactured rubber is more extensive, and a complete chemical analysis is a very tedious and complicated process. This, however, is seldom required, and often it is sufficient to subject the goods to physical tests only, of which the most important are the specific gravity, tensile strength, elongation test, sun-cracking and oxidation test, and electrical tests. These tests, of course, are applied according to the nature of the manufactured goods. An ordinary chemical analysis is confined to the determination of india-rubber, organic constituents not rubber, sulphur (free and combined), chlorine and inorganic constituents other than chlorine and sulphur.

Gutta Percha and Balata. Gutta percha is obtained from certain trees appertaining to the botanical family *Sapotaceæ*, which are found growing wild in the Malay Archipelago. The original gutta percha tree, Dichopsis gutta, or Palaquium, or Isonandra gutta, is almost extinct, its place having been taken by the Palaquium or Dichopsis oblongifolium, which yields excellent gutta. Three other varieties, namely, Palaquium Borneense, P. Treubii, and P. Vrieseanum, also supply gutta of very good quality. Less fine gutta percha is obtained from the Dichopsis Calophylla, D. Selendit, D. Krantziana, the two latter yielding a hard product unsuitable for cable insulation. Mention must also be made of two other gutta-producing trees—*i.e.*, Payena Lerii and Bassia Parkii. Native methods of collecting the latex are ruinously extravagant, the trees usually being felled; it has now been found, however, that gutta percha can be extracted from the leaves and twigs of the trees by means of a suitable solvent, such as toluol. The manufacturing process for gutta percha consists of kneading and washing operations. Its most important application is for insulating submarine and other cables, as its resistance to the electric current is unequalled by any material of a similar nature. Certain plants Mimusops balata, M. globosa, and M. electa, also belonging to the *Sapotaceæ* order and found in the north of South America, yield a hornlike substance, resembling, yet distinct from, gutta percha. This material, *balata*, is largely used for the manufacture of driving belts, for which it is excellently adapted, being very tough and inelastic, although liable to become sticky if heated. The process of manufacturing balata belts is essentially the same as described under Rubber Belting, with the exception that no vulcanisation is needed.

RUBBER AND GUTTA PERCHA *concluded; followed by* BASKET-MAKING

FISH AND THE FISH-MARKETS

Immature Fish. Artificial Hatching. Diseases of Fish. Preparing Fish for the Market. Oyster Culture. Fishery Laws

By Dr. J. TRAVIS JENKINS

IN many methods of fishing, notably in *shrimping*, large numbers of undersized fish are caught, and in many instances these immature fish are unmarketable. Every haul with the shrimp-trawl in our inshore waters brings up, in addition to the shrimps, a number of small plaice, dabs, soles, herring, codling and whiting; the number of species varying according to locality and season.

Protection of Immature Fish. These fish are unmarketable, but if allowed to remain in the sea a proportion would presumably become of marketable size and be captured by the fisherman. If the shrimp trawls are hauled at short intervals and the net rapidly cleaned and the young fish promptly returned overboard, it is certain that a very large percentage of the flat fish would be uninjured, and they may be seen swimming away as soon as they are replaced in the water. With regard to the round fish it may be said that they are far more susceptible to injury, and extremely prompt measures are requisite to secure that any reasonable proportion be returned to the sea alive. There can, therefore, be no reasonable doubt that many millions of undersized fish are captured by shrimpers in their trawl-nets, push-nets and shanks; and formerly a very large proportion of these were destroyed. The process of separating the shrimps from the fish and other *debris* caught in a trawl is accomplished by *riddling*, and where such riddling is promptly done and the debris and fish returned overboard immediately, little harm is done. Of course, the shrimper naturally selects ground where shrimps are most abundant, and the young fish are caught accidentally; and in this respect the shrimper differs from the whitebait fisherman, who intends to capture undersized fish, for which he readily finds a market.

How to Stop the Needless Destruction of Fish. Where there is a market for undersized or immature fish, though it might be advisable to have the fishery carried on within reasonable limits, since obviously a certain proportion of adults must survive to propagate their kind, it would be as absurd to prevent it altogether as it would be to stop the sale of veal or lamb.

But in cases where the fish are caught accidentally or sold for manure or needlessly destroyed, prompt measures are necessary for the maintenance of the fishery; and where destruction is of a gratuitous nature there can obviously be no sympathy with the person responsible for the damage, though at the same time where he is carrying on a bona fide business it becomes necessary to interfere with him as little as possible.

The most practicable method of dealing with a problem of this kind is to interfere as little as possible with the implements of fishing, but to see that they are not needlessly destructive, and in any case to see that they are used in a proper manner. The prevention of landing of fish under a certain size would effectually stop the fishing *for* undersized fish as distinguished from shrimping, where the undersized fish are accidentally present. Various enactments have been proposed for dealing with this evil, which is admittedly serious. Bill after Bill has been introduced into successive Parliaments, but not being party measures they have had no chance of being passed. But in the territorial waters local regulations, confirmed by the central authority (the Board of Agriculture and Fisheries), have dealt with, and, to some extent, undoubtedly checked, this wholesale and wasteful destruction. The fixing of a size limit below which fish could not be landed would effectually stop the fishing for undersized fish which goes on at present. The protection of the immature fish in the territorial waters may well be left to the local authorities.

Artificial Hatching and Rearing of Marine Food-fishes. A certain section of scientific experts, being firmly convinced that a depletion of the seas was in operation, suggested that man might, by artificial hatching and rearing of the fry of economic fish, restore the balance of Nature. The initiative with regard to the erection and equipment of marine hatcheries is due to the United States authorities, who regarded this plan as more suitable than attempting to prevent the destruction of immature fish by restrictive legislation—an alternative method which had been suggested as a remedy for over-fishing and its evil consequences. The whole *modus operandi* of the marine pisciculturist is, we believe, based on fallacious reasoning. But this is not the place to enter into destructive criticism of his efforts; we are merely content to describe what is claimed to have been done.

1,500 Million Fish Hatched. The United States Fish Commission during the year 1902 claim to have hatched and liberated nearly 1,500,000,000 fish fry, the principal salt-water fish dealt with being cod, flounders and lobsters. The Canadian hatcheries deal mainly with cod and lobsters. The European countries which have adopted artificial hatching are Norway, Scotland and England. The methods in vogue for obtaining fish eggs vary in the different establishments, but in England the mature fish are obtained by trawling from a special steamer some months before the spawning season begins. These fish are kept in tanks or open-air ponds attached to the hatcheries, and are claimed to constitute a reserve of spawners. The eggs are artificially fertilised and then placed in the hatching-boxes, there to undergo their incubation.

The hatching-boxes are kept in constant motion by an automatic arrangement, and a current of sea water is maintained through the boxes. This serves the double purpose of oxygenating the eggs and preventing their settling. Up to the present no successful attempts have been made to rear the fish, the fry being set free a few days after hatching, or never later than after the absorption of the yolk-sac. These larvæ are (or should be) liberated on the off-shore spawning grounds, their natural habitat. No satisfactory evidence has yet been adduced that sea-fish hatching is an economical success. Originally it was doubtless worth an extended trial, but until rearing the fish as well as hatching them has been accomplished one must reserve one's opinion as to the efficacy of this method of replenishing the sea.

Fish Diseases and Parasites. Fish, like other animals, are subject to "the ills that flesh is heir to," but the alarmist statements that have of recent years appeared in the public Press are quite without foundation, and it may once for all be said that no article of diet can be regarded as so absolutely free from disease as sea fish. The complaints from which fish suffer may be grouped under two headings; firstly, the attacks of parasites, either attached to the body externally (*ectoparasites*), or dwelling in the inside of the fish's body (*endoparasites*); and secondly, infectious diseases due to the presence of vegetable organisms (*bacteria*) or animal organisms (*sporozoa*). Of course, both bacteria and sporozoa are, strictly speaking, endoparasites.

The important question as to how far, if at all, the communicability of diseases from fish to man or vice versâ is possible merits a brief notice. It is perfectly obvious that this question of the purity of fish as a food supply has the most important practical bearings, and the recent "scare" with regard to the connection of oysters and typhoid is a case in point. That shellfish may, under certain extreme circumstances, be the means of communicating such a disease as enteric or typhoid fever to human beings seems to be well established, and not only oysters, but mussels and—though less certainly—cockles may occasionally be held responsible. This is, however, never due to the fact that the oyster is itself "suffering" from the complaint, but rather that the typhoid bacillus is accidentally present either in the food of the oyster or in the sea water enclosed in the shell. Modern research tends to prove that if reasonable care be taken in the selection of the site for bedding oysters, and if ordinary cleanliness be secured in the handling and preparing of the bivalve for the market, the risk of pollution is infinitesimal and certainly not greater than is the case in many other articles of consumption, notably milk. The danger is reduced to vanishing point if the shellfish be thoroughly cooked.

Fish and Human Diseases. Within the last few years considerable attention has been devoted to the study of the diseases of fish, and a review of the literature devoted to the subject is rather a source of satisfaction than dismay. The diseases such as smallpox, phthisis, and dropsy, which have been popularly attributed to fish, disappear or become something quite different on closer inspection.

Fish, however, are undoubtedly attacked by such parasites as thread-worms, tape-worms, and leeches. The *worms* are generally found in the intestines and are removed with them. Leeches are rare and drop off when the fish are caught. Certain *crustacea* (parasitic copepoda) attack fish and are found attached to the gills, fins, eyes, and even in the nostrils. They, however, in most cases, only cause a temporary inconvenience. There remains, then, a few diseases attributable either to bacteria or sporozoa. An instance of the former is the well-known *salmon disease*, which was formerly thought to be due to a fungus (*saprolegnia*). An instance of the latter is shown in the figure of the flounder [14]. In all cases where a fish suffers from complaints of this kind the body is unsightly, being marked with blotches or swellings which would immediately cause it to be rejected for food. In conclusion, though isolated instances of fish (chiefly fresh-water species) suffering from disease are, from time to time, recorded, in no case is the disease identical with any human complaint, and in every case spots or swellings are visible which would render the fish unmarketable. Nothing is said about unwholesome fish where the deterioration is due to the fish having been kept too long; naturally, fish, like other perishable articles, require to be eaten in as fresh a condition as possible.

Preparation of Fish for the Market. Fish, if not speedily placed on the market, deteriorates rapidly, and hence we find a large number of methods of preservation. All these methods depend for their efficacy upon the necessity of eliminating the action of the bacteria responsible for the putrefactive changes which so rapidly take place. A second and most essential purpose to be borne in mind is the preparation of an article which shall at the same time be palatable and be capable of retailing at a reasonable price The methods of preserving fish fall under four main heads—namely, by *ice*, *salt*, *smoke*, or *canning*. It must be understood that these methods are not absolutely distinct; a fish may, in the course of preparation for the market, go through two or more of these methods in succession. A description of the multitudinous modes of manipulating the raw material would fill the pages of a considerable volume, and therefore the only accounts given here are those which are practicable on a small scale. *Canning*, which requires special plant and is quite distinct from fishing proper, is not touched upon.

14. FLOUNDER ATTACKED BY A SPOROZOAN PARASITE

The "Finnan Haddies." There are, broadly speaking, three essential stages in the preparation of "finnans." These are splitting, salting, and smoking. The operation of *splitting*, to be rapidly and efficiently performed, requires actual practice. The head is removed, the fish split down the back and eviscerated. It is then *salted* for about half-an-hour in strong brine, then drained, and afterwards smoked. The smoking is now carried on in small houses built for the purpose, the fish being spread open and suspended in tiers. The fuel used is peat, and the operation is continued without interruption for from four to six hours, during which period the fish requires constant attention. The fish are generally put up in boxes of the average weight of 40 lb. The barrels are about four times as heavy. For export purposes "finnans" are *canned*, but as these fish must be cooked, or at least boiled, before canning, in addition to the processes above described, it seems a misnomer to call them "finnans." In addition to finnans there are other varieties of prepared haddocks, notably "smokies," where the fish are smoked over a hot fire, with abundance of smoke, until they have taken a golden colour; and "pale smoked haddocks," where the fish are but slightly smoked for immediate consumption.

The Preservation of Herring. The four chief methods of preserving herring are best enumerated under the headings by which the resulting product is known to the public—namely, *pickled herring, kippers, bloaters* and *reds*. The *bloater* is intended for immediate consumption and may be described as a round or unsplit herring which has only been slightly salted and smoked. The fish, as soon as possible after capture, are dry salted for from six to twenty-four hours—the time being longer if the fish be fat—and afterwards smoked. The *red* is generally prepared for foreign consumption, and large quantities are exported to the Mediterranean. For this trade the herrings are salted in brine for about two days and then smoked for a fortnight. The wood and sawdust used is of the "hard" variety, and from this the peculiar flavour of the red is derived. The red may be defined as a round herring, heavily salted, and smoked for a long time. They are packed chiefly in barrels and half-barrels, the former containing from about 500 to 600 fish.

Kippers and Pickled Herrings. *Kippers* are first of all split and eviscerated, then salted in strong brine for from a quarter of an hour to an hour, then spread out and smoked over hardwood shavings. The time of smoking varies, being longer at Yarmouth than at Aberdeen. *Pickled herrings* are more numerous than all the other varieties put together. These fish have their gills and intestines removed. They are then brine-salted and packed in barrels and half-barrels. In Scotland these herring may be tested by the Fishery Board. If the merchant desires a certificate of the quality of the fish in his barrels, an officer of the Board opens and examines samples of these barrels, and if the contents come up to the required standard a brand is burned into the head of the barrel. A barrel generally contains 300 lb. of herrings, and each barrel is packed with great care, with alternate layers of fish and salt.

Fish Markets. Broadly speaking, the marketing of fish is left to a special class of individuals—fish auctioneers and salesmen. Even fresh fish is rarely disposed of by the fisherman himself, and the bulk of preserved fish and fish products he never sees.

Fish that is landed at any of the larger fishing ports, such as Hull, Grimsby, Billingsgate or Aberdeen, is sold by auction on the quay. The fish is sorted into baskets or other receptacles, or may even be spread out on the quay floor as at Aberdeen, and the sale is invariably held by auction at an early hour in the morning.

Even fish that is landed by smaller boats at the quieter fishing ports is, to a very large extent, sent to large centres to be disposed of by auction, some occasionally even returning over the same ground for local consumption. The marketing of fresh fish is now such a special occupation that there is a considerable amount of truth in the complaint of visitors to seaside resorts, like Llandudno or Tenby, that they have to wait for the train from Grimsby before they can procure any fresh fish. Many markets for preserved fish are met with abroad, pickled herrings being an especial favourite with the Latin nations.

Oyster Culture. On the Continent *oyster culture* forms a considerable industry, absorbing a large amount of capital and affording employment to thousands of people; but in England, for various reasons, this industry has not been developed to the same extent. The success of oyster culture depends to some extent, as for instance at Arcachon, on the natural physical advantages of the locality. At Arcachon there is a large inland sea of about 30,000 acres area, which communicates with the sea by means of a narrow entrance, through which the tide ebbs and flows. In this lake the oyster reproduces itself naturally. The young stage of the oyster, known as the *fry* or *spat*, is of microscopic size, and swims about in the water for a time, and eventually settles down on suitable objects, there to develop into an adult oyster. [See NATURAL HISTORY, page 3286.]

Spatting. The success of oyster culture depends upon the simple fact that the spat can easily be collected upon suitable objects. The oyster reproduces itself in spring or early summer, and the free-swimming stage lasts for about a week. At the time settling-down process begins, receptacles or collectors are placed in position. The Romans used bundles of twigs; the Dutch use earthenware tiles; in France the collectors are crates of similar tiles coated with a cement of lime and sand, which offer a convenient adhesive medium for the *spat*. The tiles are arranged in rows inside large cases, and in Arcachon alone about 12,000,000 tiles are annually laid down for this purpose. The spat is left on the tiles until the following October, when the young oysters are about the size of a finger-nail, at which stage they are known as *seed oysters*.

Rearing and Greening. They are now removed from the tiles and are taken in hand by the "éleveurs," who rear and fatten them to a marketable size. This is done by arranging the *seed* on flat trays of galvanised wire netting, which are placed in shallow oyster "parcs" in which the tide circulates. Great care is taken with the rearing process, the oysters being constantly looked after by men and women who inspect the trays at low water and remove impurities and enemies, such as starfish. Thinning out is soon necessary, the growing oyster being removed to other trays or transferred to the floor of the "parc," which is often suitably prepared for their reception.

The process of *greening* is undertaken at Marennes, where the oysters are kept in muddy salt-ponds, in which they gradually become green, owing to the presence of a particular diatom in their food. At the same time they acquire a peculiar delicate flavour.

The Board of Trade Certificates for Fishermen. According to the provisions of the Merchant Shipping Act of 1894, no trawler of 25 tons tonnage or upwards shall go to sea from any port of England or Ireland unless there is on board a duly certificated skipper and a duly certificated mate or second hand.

Every fisherman with a spark of ambition will be interested to hear what kind of certificates are issued and what is the best way to set about obtaining one. The Board of Trade examines candidates for certificates of competency, and there are no less than ten different kinds of certificates to be obtained by any fisherman who is prepared to sacrifice a little of his leisure time. Five different certificates are issued to mates (second hands) and five to skippers.

A Mate's "Ticket." To obtain Certificate A, which is issued to *second hands* who fulfil the necessary conditions and pass the required examination, several preliminary qualifications are requisite. The candidate must not be less than nineteen years of age, and he must have served at least four years at sea, of which two years must have been on board a deep-sea fishing boat. If he has served his time the candidate should apply to the nearest Mercantile Marine Office for a form of application, and he must take care to fill this form up properly. When the form is returned to the Office the candidate must attach to it his testimonials of general good character, and of sobriety, experience, ability, and good conduct on board ship. A fee of 1s. is charged for the examination. The candidate will be examined as to his vision, and, in addition, the rule of the road at sea, the marks on the lead-line and the use of the lead, taking bearings by compass, ability to use a chart, and generally as to the duties of a second hand. Questions regarding the rules of the road at sea are illustrated by means of models of vessels, and various coloured balls, representing lights, are used to represent vessels at night. Mates or second hands are also tested as to their abilities in reading, writing and arithmetic.

A Skipper's "Ticket." Candidates for certificates as *skippers* (Certificate B) must have served five years at sea, of which one year must have been as certificated second hand on board boats of 25 tons tonnage and upwards, engaged in the method of fishing for which the certificate is desired. An applicant for a certificate as skipper must be not less than twenty-one years of age. In addition to the subjects enumerated for second hands, skippers are required to be acquainted with general duties required for skippers, such as getting under way, what to do when engines are broken down, or when the vessel has sprung a leak, or when the rudder has gone, or on the use of a floating anchor. They are also required to make themselves acquainted with their civil duties under the Merchant Shipping Act of 1894; for instance, as to the returns of the list of crew, or as to agreements or apprentices' indentures. For extra certificates the applicant must show a knowledge of the use of the quadrant and be able to take observations, to read on and off the arc, to find the index error by the horizon, and to determine the latitude by the meridian altitude of the sun [see NAVIGATION].

Certificates for "Skippers of Steamers." Candidates for certificates as second hands and skippers of *steam* fishing vessels only have a somewhat similar examination to pass, but with the exception that they are not required to answer questions relating to such subjects as tacking and wearing, or rigging and masting of fishing vessels, or generally as to matters not required on steam vessels. Should the candidate not feel equal to any of the above tests, and be unable to pass the full examination, the examiners may, if they think fit, report that he has passed a limited examination, provided he has passed the sight tests and they are satisfied that he is competent to take charge of a fishing boat and that he is acquainted with the rule of the road at sea. Various County Councils have now instituted classes in subjects for certificates for management of fishing boats, and as a good deal of the instruction is of a practical nature, and cannot be learnt from a book, the candidate is advised to make local inquiries as to such classes.

Sea Fishery Law. The history of the legislation applied to the sea fisheries does not afford the student very pleasant reading. All the older legislative efforts of Parliament were based on a profound ignorance of the technique of the fisherman's craft. We are, however, not so much concerned with what the legislation has been as to what it is now, and along what lines its future development may be expected. The words of Professor Huxley (Inaugural address, Fisheries Exhibition, 1883) have lost none of their force at the present day, and as they embody the maxims or axioms which are fundamental they may well be reproduced here.

"Every legislative restriction means the creation of a new offence. In the case of fishery, it means that a simple man of the people, earning a scanty livelihood by hard toil, shall be liable to fine and imprisonment for doing that which he and his father before him have, up to that time, been free to do. If the general interest clearly requires that this burden should be put upon the fishermen—well and good. But if it does not—if, indeed, there is any doubt about the matter—I think that the man who made the unnecessary law deserves a heavier punishment than the man who breaks it."

The Necessity for Knowing Fishery Law. At the present day when considerable capital is devoted to the building and equipment of large and powerful vessels which fish to some extent near the territorial waters of foreign countries in addition to the waters of England, Scotland, and Ireland, the skipper of such a boat has to be acquainted with a not inconsiderable body of legislative enactments, which are here briefly summarised.

In the first place the whole of Part IV. of the Merchant Shipping Act of 1894 deals with fishing boats, but as the skipper of every English trawler over 25 tons tonnage undergoes an examination as to his knowledge of this section of the Act before he obtains his captain's certificate it will be unnecessary to do more than point out the main features of the Act. All fishing boats are (or should be) conspicuously numbered and lettered, and when fishing at night should carry certain lights, the details being given in the Act. Other regulations relate to the fishing boat's register, to discipline, to apprentices, and agreements with seamen. This Act, of course, applies to British fishing boats even outside British territorial waters. Other regulations for fishing may be divided into two groups:

(1) Those which are enforced on the high seas, or beyond the territorial limits.

(2) Those which are enforced only within British waters.

Regulations in Territorial Waters. There are three Acts which define the territorial waters within which His Majesty's subjects have the exclusive rights of fishing. The Convention Act of 1843 defines certain waters which are to be reserved for French and English fishermen in their respective countries, and here, in addition to three geographical miles from low-water mark (the distance allowed by international law), we find bays, the mouths of which do not exceed ten geographical miles in width, also reserved, and the limit is to be reckoned as being distant three miles to the seaward of a straight line drawn from low-water mark off one headland to low-water mark off the other headland of such bay respectively. By a subsequent Act of 1868, which, like the act of 1843, was intended to carry out a convention between England and France, we find a similar definition, except that the straight line across the bays is to be drawn from "headland to headland," no mention being made of low-water mark. This convention was never carried out by France, the necessary legislation to make it operative never having been passed. A later Act (of 1883) defines exclusive rights of fishery as regards bays, and states that the distance of three miles shall be measured from a straight line drawn across the bay in the part nearest the entrance at the first point where the width does not exceed ten miles. This Act carries out a convention between England, Germany, Belgium, Denmark, and Holland. No definition of a "bay" is given, but presumably any indentation of the coast line is a "bay" within the meaning of the Act.

It must not be assumed that the exact delimitation of the territorial waters is a point of merely theoretical importance. Some of the laws restricting steam trawling in foreign territorial waters are very stringent. For instance, trawl fishing within the territorial waters of Iceland is punishable by a fine not exceeding 4,000 kroner (£220), together with forfeiture of all the fishing gear, including the drag ropes. That heavy fines are not infrequently inflicted English skippers know to their cost. Even to enter Icelandic waters with a trawl on board, not stowed away, is punishable by a fine of 2,000 kroner, and the ship, catch, and fishing gear may in either of these cases be seized and sold to cover the legal expenses.

Regulations for Home Waters Apart from the question of *territorial waters*, which are reserved to native fishermen, we have to deal with restrictions applied in the British Islands, and at the outset a fundamental difference is to be noted. For England and Wales, although the Board of Agriculture and Fisheries is the central authority for sea fisheries, the bylaws regulating the industry are formulated and administered by local Sea Fisheries Committees, which were called into existence by the Sea Fisheries Regulation Act, 1888. Although these bylaws are formulated by the committees they need the sanction of the central authority before they become operative. In Scotland and Ireland, on the other hand, the administration of bylaws is controlled by a central authority, and this distinction is accompanied by an extension of the area under control, for whereas in England and Wales bylaws only apply to the territorial waters, in both Scotland and Ireland the jurisdiction of the central authority extends beyond this. Naturally this extra-territorial authority can only be enforced against British subjects, at any rate, as long as their vessels fly the British flag, and already extensive evasions of the bylaws are practised by British owners who have placed their vessels under an alien flag.

In Scotland trawling is absolutely forbidden in territorial waters (the Herring Fishery [Scotland] Act, 1889); it is also forbidden in certain Scottish waters outside the three-mile limit, notably in Moray Firth and Firth of Clyde, and fish caught by trawlers flying a foreign flag in these waters must not be landed in Scotland, though they may be in England.

In Ireland no extensive advantage has been taken of Section 3 (1) of the Steam Trawling (Ireland) Act of 1889, which allows the Inspectors of Irish Fisheries to prohibit "beam-trawling or other trawling within three miles of low-water mark of any part of the coast of Ireland, *or within the waters of any other defined areas* specified in any such bylaws, and subject to any conditions or regulations contained in such bylaws." There are, however, certain extra-territorial waters closed under bylaws made in pursuance of this section, notably off the coast of Waterford.

Fishing Grounds at Home and Abroad. In England, trawling from steam vessels is practically prohibited within three miles from the shore; trawling from sailing vessels is only allowed with nets the meshes of which are a certain size, and there are in various localities regulations as to the tonnage of sailing trawlers. Certain grounds are closed to all kinds of fishing but lining. There is at present no regulation as to the size at which *sea fish* may be landed or exposed for sale, but such regulations are in force for shellfish.

Shellfish are frequently protected by closed seasons, and berried lobsters and crabs may not be removed from a fishery. Broadly speaking, the local fisheries committees absolutely prohibit wasteful and destructive methods of fishing. The powers of district committees are very extensive with regard to prevention of certain methods of fishing, or the regulation of fishing implements, but do not extend to imposing a size limit for sea fish. There can be little doubt that a measure prohibiting the landing of certain specified classes of sea fish under a certain size would be beneficial to the industry at large.

Steam trawler skippers who fish in the vicinity of foreign waters have to be careful. As a rule, the fines inflicted are excessive, being far above the modest £20 which is the maximum "penalty" in England and Wales; moreover, either to be in foreign waters with implements of fishing on board not stowed away or with the *intention* of fishing is in some cases punishable. That this regulation may at times be pushed to, or even beyond, its logical limits is evidenced by a recent decision of the German Appeal Court, at Leipsic, which decided in the case of the smack Lady Godiva that the presence of a foreign fishing boat in German waters with the *intention* of fishing was an offence equivalent to that of actual fishing.

Fisheries in the British Empire. Fisheries in the British Empire are in various stages of development. The Canadian fisheries both on the Atlantic and Pacific coasts are extremely well organised and are exploited to a high degree. The Canadian Government, unlike our own, is a disbeliever in the policy of *laissez faire*, and does everything in its power to encourage the fisherman. Not only are bounties paid to fishermen under certain conditions, but when points of special difficulty arise they are promptly dealt with. For instance, of late years the Canadian fishermen, like our own, have been troubled with a plague of dogfish. The Home Government do nothing. The Canadian Government have erected several dogfish reduction works where the fish may be taken by the fishermen and converted into commercial products of some economic value. Both in Australia and at the Cape the fisheries need exploiting, and probably the introducer of trawling on modern principles to either of these colonies will meet with a substantial reward. With regard to India, Major Maxwell, who represented the Indian Government at the International Fishery Congress at Vienna in 1905, said: "The fisheries of India are entirely undeveloped. Deep-sea fisheries as known in Europe are practically non-existent. The sea, however, contains incredible numbers of fish of all species. The population of India is over 300,000,000, and the great proportion would consume fish if they could get it. The riches to be gained by the exploitation of these fisheries would surpass the wildest dreams of avarice."

FISHERIES *concluded; followed by* FOOD PRESERVATION

TUBE MANUFACTURE

Cast-iron Pipes. Pipe Founding. Butt and Lap Welded Tubes. Seamless Tubes and their Manufacture by Various Processes

INTO how many articles of domestic, industrial, and public utility does tubing enter? We do not intend to supply the answer, for we cannot, but the question may cause the reader to look around him, and he will be surprised at the innumerable uses of tubing. The first use of metal tubing was for the manufacture of gun-barrels. The need for cheaper tubing than gun-barrels provided came with insistence during the early years of last century. The introduction of gas lighting called for very large quantities of tubing, and at first the need was met by old gun-barrels, of which there was a plethora after Napoleon had been finally housed in the island where he died. Then with the need for cheaper tubing came invention, and the files of the Patent Office contain the records of very many attempts to solve the problem of tube manufacture, each vieing with each in efforts after economy and quality in tube production. But we have to do with the practical, not with the historical, side of the question, and we may proceed to examine modern processes of tube manufacture.

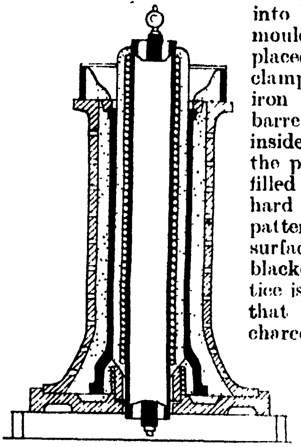
The word *tube*, or *tubing*, and the word *pipe* have the same meaning, and have been defined as "anything hollow or concave, and with some degree of length." The definition is comprehensive, and would include a nut or a washer. But length is the conspicuous feature of a tube, and anything so short as a nut or a washer would not come under the definition of a tube, although technically both of these articles are short tubes. The word "pipe" is usually applied to tubes of cast iron, and also to those of lead, but tubes of wrot iron or steel and of metals other than lead are usually designated by the word "tube." The difference is merely a matter of habit, and has become fixed. It is convenient, because to talk of an iron pipe is accepted as meaning something of cast iron, and an iron tube implies something of wrought iron.

Cast-iron Pipes. The chief use of cast-iron pipes is for water and gas mains. The usual length in sizes under 3 in. internal diameter is 6 ft., and for larger diameter pipes the length is usually 9 ft. American practice favours 12 ft. lengths for large water pipes, and there is economy in the longer length as there is then occasion for fewer joints.

Iron pipes are usually cast in a vertical position, and usually also with the socket end at the bottom. The practice is not universal, for small pipes are often cast in the reverse position, but the desirability for strength in the socket part constitutes a reason for it.

Cast-iron pipes are made by dry-sand moulding, which is the best and cheapest process where the metal is poured under any great head of pressure. This process of moulding does not demand so much skill as greensand or loam moulding, and consequently it produces cheaper work. Indeed, skilled labour is almost dispensed with in pipe founding. In the most improved practice the casting pits fill the purpose of core ovens as well. This utilises the heat left from the casting. When being used as ovens the pits are covered and flues admit the hot air.

The Moulding-box. The moulding-box [1] is made in two halves, and has a hinge joint, enabling it to be opened longitudinally. It is provided with perforations for the escape of gases as the metal is being poured, and also as the moulds are drying. The size of the moulding-box is sufficient to allow about 2 in. of sand between it and the pattern. Its base is made separate from the main shell, and before the moulding-box body is placed upon the base a cast-iron pattern of the socket is clamped into its place. Then the moulding-box or flask is placed upon its base and clamped thereto, the cast-iron pattern for the pipe-barrel is put into position inside it, the space between the pattern and the flask is filled with sand and rammed hard with long rods, and the pattern is withdrawn. The surface of the mould is now blackened. A common practice is to pour black-wash—that is, finely-powdered charcoal made with water into the consistency of cream—into it, care being taken that it gets around all the surface. The mould is then dried.



1. MOULD FOR CASTING PIPES

The moulding-boxes, after ramming, are placed over apertures, which are exhaust flues. The heated air entering the pit or oven—for in this capacity it is being used—passes up round the exteriors of the moulding-boxes and descends through the mould to the exhaust. After the moulds are dry the moulding-boxes or flasks are set in position for the pouring.

Preparing the Core. The core ought to be ready for insertion at this stage. Its preparation has been simple. Upon a long shaft, or arbor, is wound tightly a course of straw or hay rope of about ¾-in. diameter. This is done by placing the shaft or core bar upon trestles with grooves, in which the bar may rest, and by turning it with a handle fitted to its end. When one layer of rope has been put on, soft loam is applied and rubbed in between the spirals of rope throughout the whole length; then another course of rope is wound on, and more loam applied until the internal diameter of the pipe to be cast is reached. A loam board or *strickle-board*—that is, a templet the form of the edge of the longitudinal section of the desired core—is used to give it shape. The core may be partially dried during the process, otherwise the mass of loam and core rope would not be sufficiently cohesive to remain unbroken. It will also probably be bound with iron wire for the same reason. Then it has a last coating of sifted loam, sometimes mixed with sawdust, made thin with water, is "stricked," or made true to templet, and is finally dried. In pipe founding the core bar is allowed to remain inside the core in the mould so as to give it strength, as a long core is necessarily weak. The core must have a diameter slightly larger than the internal diameter of the pipe desired, as the iron shrinks in cooling, the approximate shrinkage and the usual practical allowance being ⅛ in. to every foot of diameter.

The cores made as described are treated to blackwash, as was the mould, and are then inserted within the mould.

The socket core is wrapped with hay rope and plastered with loam in the same way as the centre core, being also stricked by a templet and dried in the manner already described.

Collapsible iron bars have been tried instead of rope cores, as the latter are an expensive item in pipe founding, but they have not come into general use.

Casting a Pipe. The molten metal is usually poured from the top of the moulding-box, but sometimes large pipes have as much metal as will cover the socket-core poured from the bottom by a gate through the mould to the socket, the metal for the body of the pipe being poured from the top in the usual way. By this method there is less danger of injuring the socket-core by the heavy drop of metal upon it, but it gives the possibility of a "cold shut" between the metals of the two pourings.

Whenever the iron has set, the core bar is withdrawn by means of the crane, so as to prevent any danger of the pipe cracking as it cools, and the straw that is left at once begins to burn. When the pipe has dulled down to black, the shell of the moulding-box containing the pipe is hoisted up and placed over skids, where it is opened and the pipe rolled out upon the skids.

Flanged pipes are made in practically the same way, but it is a common practice to have a separate moulding-box for the lower flange and to clamp it on the cylindrical moulding-box used for the pipe body, the upper flange being made with a templet attached to a ring revolving on a pivot on the pattern, and a space being left for the cover.

Pipe Sizes and Weights. Cast-iron pipes are made from ⅜-in. thick to 1¼-in. thick, and the following table gives the range of thicknesses in which the various sizes are made with the weight of each per lineal foot.

Dr. Angus Smith's solution is in very wide use for coating pipes that are to be laid underground. It gives the pipes a coating impenetrable to the liquid or other matters that usually pass through drain and water pipes, and it prevents corrosion. The original recipe took 60 gallons of coal tar, 60 lb. of freshly slaked lime, 12 lb. of tallow, 6 lb. of lampblack and 3 lb. of resin, all mixed together, boiled for half an hour, and applied hot. Present-day practice has departed from this, and there is not strict uniformity. A good method, largely followed, is to put coal-tar in a dipping tank large enough to accommodate the pipe to be treated, then to add one-seventh part by volume of pitch in powder form, and one-seventh part of coal oil. The pipes are heated to just under boiling point, say 200° F., and are placed into the mixture, turned over for a few minutes, and then withdrawn and allowed to drain.

Welded Tubes. Many improvements have been made in the processes of tube manufacture during the last fifty years. These have been chiefly in the making of seamless tubes. Welded tubes are made practically as they were made three-quarters of a century ago. There may be slight difference in the details of the process, but the principle has not been changed.

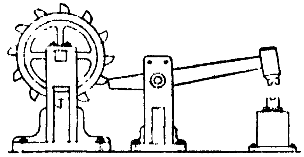
Welded tubes may be divided into two classes—*butt-welded* and *lap-welded*. In both cases a strip of flat metal is bent round into tubular form by special apparatus. Butt-welded tubes are those where the bending of the strip causes the two edges to *butt* or touch each other, and in this position they are welded. Lap-welded tubes, on the other hand, are bent round so that the two edges overlap, and in this position they are united by welding. A lap-welded tube must have a mandrel or solid rod inside when it is being welded, but a butt-welded tube can be welded without internal support during the process. Thus, very small tubes can be made butt-welded, but not lap-welded. Butt-welded tubes of iron are made as small as ⅛ in. internal diameter, and they could be made even smaller, but the minimum internal diameter of lap-welded tubes is considered to be about 1 in. The manufacturer of welded tubing purchases "rolled strip" from the iron-rolling mills. This rolled strip is simply iron hoop or plate in the form of strips of the width necessary for the tubes about to be made. He converts this strip into "skelp," or tubes, the edges of which touch or overlap, but are not welded together. This is done by passing the strips through rolls, which first curve it and then bend it round until the edges touch or overlap.

Formerly, the tilt hammer process [2], patented eighty years ago by James Russell, of Wednesbury, was the common practice, and may still be followed to some extent. By this process the roughly-formed tube was heated to welding heat and passed along the grooved anvil of a tilt hammer, caused to strike rapid blows by the rotation of a wheel with projections as seen in the illustration. A mandrel was placed inside the tube being welded, if exactness in the internal diameter was desired, but if such exactness was immaterial, no mandrel was used. The invention of this process was an important stage in the development of tube manufacture, as it proved that a rough tube heated to welding temperature could be welded up merely by having its edges placed in contact and pressure applied, and without the need for the employment of an internal mandrel such as had been previously used.

WEIGHT OF CAST-IRON PIPES IN POUNDS PER FOOT

Bore in Inches	Thickness of Metal in Inches						
	[illegible]			¾	⅞	1	
	8·7						
	12·4	17·1	22·2				
	16·1	22·1	28·3				
	19·8	26·9	34·4	42·3			
	23·4	31·9	40·6	49·7			
	27·1	36·8	46·7	56·8			
8	30·8	41·6	52·8	64·3			
9	34·4	46·0	58·9	71·7			
10		51·4	65·1	79·0	93·3		
11			71·0	86·4	102·0		
12			77·3	93·7	110·4	127·4	
14			89·6	108·4	127·5	147·0	
15				115·7	136·1	156·8	177·7
16				123·1	144·7	166·6	189·7
18				140·0	161·8	186·2	210·8
20					178·9	205·8	232·9
22						225·4	254·9	285·0
24						245·0	277·0	309·4

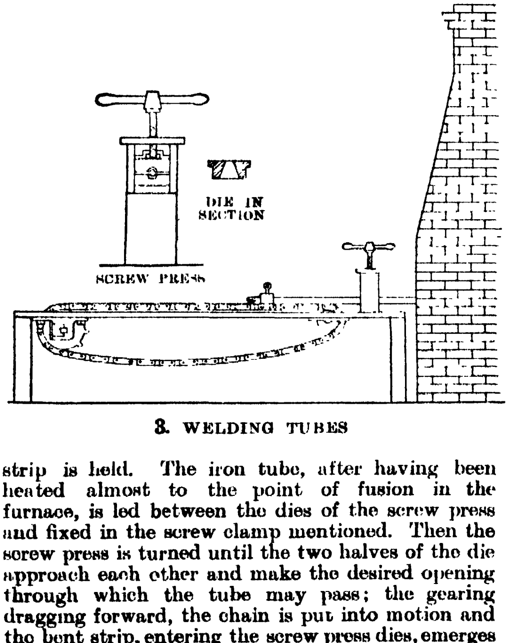
During the year after Russell began to exploit his patent, Whitehouse, of Wednesbury, introduced his draw-bench process, which is that still used, and which is best described in the words of the original specification (No. 5109, of 1825).



2. RUSSELL'S PROCESS FOR WELDING TUBES

"I prepare a piece of flat iron, commonly called plough-plate iron, of a suitable substance and width, according to the intended calibre of the tube. This piece of flat iron is prepared for welding by being bent up on the sides, or, as it is commonly termed, turned over, the edges meeting, or nearly so, and the piece assuming the form of a long, cylindrical tube. This tube is then put into a hollow fire, heated by a blast, and when the iron is upon the point of fusion, it is to be drawn out of the furnace by means of a chain attached to a draw-bench [3], and passed through a pair of dies of the size required, by which means the edges of the iron will become welded together."

He then describes the mechanism. The chain, which is driven forward by a spur wheel, carries a screw clamp in which the end of the metal strip is held. The iron tube, after having been heated almost to the point of fusion in the furnace, is led between the dies of the screw press and fixed in the screw clamp mentioned. Then the screw press is turned until the two halves of the die approach each other and make the desired opening through which the tube may pass; the gearing dragging forward, the chain is put into motion and the bent strip, entering the screw press dies, emerges from them in the form of a welded tube. It is withdrawn from the clamp and from the screw press. A small length of tube at the end where the chain clamp is attached is not welded. This piece is welded by returning that end to the furnace and, when it has been made white hot, by drawing it through the dies from the other end.



3. WELDING TUBES

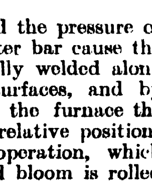
Sometimes the edges of the strips used for making butt-welded tubes are cut obliquely, making the weld thereby not a true butt, but a sort of lap. This practice makes a slightly better tube than the plain butt weld, but is still much inferior to the lap-welded tube, which we shall now consider.

Lap-welded Tubes. In its essentials the process of welding tubes with a lap weld is similar to that employed for butt-welded tubes except that a mandrel must be used to afford the necessary resistance during the operation of welding, as the pressure must be applied in a different direction to that when the weld is of the butt variety. Russell's original process (1845) which is that still usually practised, is described by its author as follows:

"The tubular skelp drawn from the furnace at a welding heat is placed upon a mandrel or what the inventor terms a 'beak iron,' which has a working surface of steel and is rigidly fixed at one end in a horizontal position, its free end projecting over a draw bench. The free end of this beak iron affords the necessary resistance and support when the lap joint of the tube, in order to weld it, is pressed upon by a roller while the tube is drawn off the beak iron by the action of the draw chain to which the grippers that have hold of the tube are attached. This system of working answers for tubes of large size, which are welded thereby at two operations, one half at a time. In making smaller tubes the mandrel or beak iron is required to be longer and of small diameter, and, consequently, as there is not sufficient substance to support the tube and its own weight horizontally without deflection, it is supported by a roller beneath the tube while the welding roller above is operating on the seam, the draw chain dragging the tube forward. The skelp in this case is drawn direct from the furnace on to the beak iron."

This process, that of rolling the skelp at welding heat and with a mandrel in the centre by one or more rollers, has been the subject of many improvements, but the only one that we shall notice separately is the Perrin process, which is, however, rather beyond the scope of an ordinary lap-welded tube.

The Perrin Process. The Perrin process of manufacturing tubes uses piled hollow blooms placed as in 4, and welded together by pressure. It is an important and a successful process, producing the apparently mechanical paradox of a seamless tube made by a welding process. The blooms are rolled into channel sections, and are placed as shown in the diagram. The edges must not butt where one channel section opposes a similar channel. This leaves room for compression, and a thorough weld between the external surfaces of the inner pair and the internal surfaces of the larger pair. When the piled blooms have been raised to a welding temperature the pressure of the uppermost outer bar upon the inner bars and the pressure of the inner bars upon the lower outer bar cause the parts to become united or partially welded along their adjoining circumferential surfaces, and by such welding before removal from the furnace the bars are retained in their proper relative positions during the subsequent rolling operation, which completes the welding. The piled bloom is rolled down at one heat sufficiently thin to form some sizes of gas, water, steam, or other tube.



4. PERRIN'S PROCESS OF TUBE MANUFACTURE

Spirally Welded Tubing. Spirally welded tubing is made and used to some extent. It is specially suitable for large tubes that have to stand high pressures. The spiral welds withstand bursting strains far above longitudinal welds. Another feature of merit is that this tube can be made in very long lengths. Also spirally welded tubing that leaks at low pressures tends to become tight as the pressure increases, and to remain so. This property may seem curious, but it may be put to the proof. If we make a twisted paper tube, close one end, and blow into the other end of it gently, the air we send in escapes at the edges of the spirals, but if we blow into it with more vigour, the tube becomes tight. Thus, internal pressure on a spirally welded tube tends to force the overlapping edges of the spirals into closer contact, and to make the welded surfaces tighter, whereas internal pressure in a longitudinally welded tube tends to open the weld and to force the edges apart.

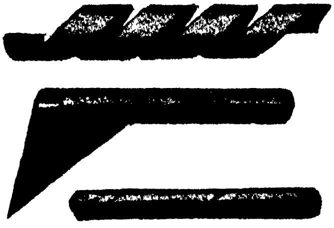
Making Spirally Welded Tubing. The process of manufacturing spirally welded tubing demands very accurate machinery. It is almost quite automatic, and does not entail highly skilled labour. The skill has been put into the machine. The "stock," or iron or steel plate, is rolled of the required width, and in as long strips as possible. The ends of these strips are welded together in a machine so as to give any desired length of strip in one piece. The completed strip or ribbon passes to the tube-making machine, which has four functions—feeding, bending, heating, and hammering. The end of the ribbon of metal is fixed to a guide table, set to the angle of the spiral, and is fed in by geared rollers. A mandrel is not employed but the mould is of a form to keep the size and alignment accurate. Projecting into the pipe, a distance a little in excess of the width of the skelp or stock used, is an anvil, cooled by water circulation and protected by firebrick. The furnace which raises the edges to welding heat is a small cast-iron box, lined with refractory material containing two nozzles, which are really blow-pipes, extruding a Bunsen flame upon the edges to be welded. One of these blow-pipes heats the edge of the pipe already formed, and the other heats the part of the skelp that is to be welded to it. The entering skelp meets the hot edge of the pipe just where the two flames from the blow-pipes meet; a hammer, with rapid blows, welds the two edges as they pass across the face of the anvil, the crimper also acting upon the work to preserve the proper curvature, and the pipe is made. The machine, acting as we have described, makes a foot of welded surface per minute.

Flanges of Spirally Welded Tubes. Spirally welded pipes are usually flanged, as this is the best way of joining them one to the other. The type of flange is what is known as the trumpet flange. The end of the pipe itself is turned over flat, thereby forming a narrow flange. The larger flange comes behind this, and has holes for bolts, so that two flanges are tightly pressed one against the other. But the strength of the union depends not at all upon the union of the large flange to the pipe, for the large flanges merely press the smaller flanges tightly together. Packing is, of course, used.

Spirally welded pipes have been made up to about 50 ft. long, but such lengths are convenient only when they are to be used close to the place of manufacture, because about 30 ft. is the longest that can be transported without the creation of exceptional facilities.

Spiral tubes, with the spirals united to each other by riveting instead of by welding, as described above, are also made to some extent, and their manufacture is cheaper than that of the spirally welded. Their chief economy is when they are of large size.

Helical Steel Tubing. Another form of spiral tubing is the so-called *helical tubing* [5] (Hillman's patent), used in the manufacture of Premier cycles. Long strips of sheet steel, usually of crucible cast-steel, is coiled round a mandrel, each spiral overlapping the preceding one to half of its width. The overlapping surfaces are then brazed together.



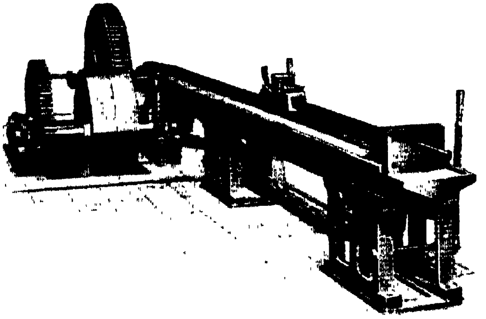
5. HELICAL TUBING

Seamless Tubing. Seamless steel tubing has many advantages over welded tubing, no matter what process of welding may be adopted. There are very many processes by which seamless steel tubing is manufactured. These processes follow one of three practices. First, there is the process of piercing the billet with a mandrel or drill, thereby making a short cylinder, to be afterwards rolled or drawn (or rolled and drawn) into the desired tube. Then there is the process whereby the billet is made with a core; and, finally, there is the wonderful Mannesmann process, whereby, under the action of rapidly revolving rollers of special construction, the solid billet is "spun" into tubular formation and attenuated to make the final tube. We shall look at these different processes in their order, selecting in the first two the main principles common to many adaptations of the process.

The manufacture of solid drawn tubes consists of two main operations — namely, rolling and drawing, the former being done while the metal is hot and the latter when it is cold. The material comes into the works in the form of billets, usually round, with a diameter of about 6 in. and a length depending upon the tube to be made, but usually from 18 in. to 24 in. The billets are, of course, solid, and the first process consists in drilling them with one hole up the centre longitudinally. Usually a special horizontal machine operating upon both ends of the billet simultaneously does this work. It is often done with the billet in a bath of water, which constitutes a lubricant for the drill and speeds up the work. The drilled billet is put into a furnace, and when it has been extracted hot, a hard steel mandrel is forced through the central hole to enlarge it. This is performed with the help of a hydraulic press.

Again the billet is heated, and the next process lengthens it, and it begins to assume a shape approximating to its final form. It is rolled between grooved rolls, while a mandrel is kept in position in the centre of the circular hole formed by the two grooves in opposing rollers. As the billet is passed through the rolls, it is forced on to this mandrel. It goes through this operation several times, each time having a smaller pair of grooves through which to pass. The mandrel over which it passes is shaped something like a bullrush, a head of the required thickness and a stem of thinner metal behind. Each pass of the tube through the grooves we have described forces it over the mandrel and on to the stem, whence it has to be removed to be passed through again until it is sufficiently drawn. With tubes of small diameter the bar or stem of the mandrel cannot be made sufficiently strong to withstand the resistance offered by the tube as it is being forced on; so in this case the tube is first put on the mandrel stem and then drawn over the head through the grooved rollers. By this means the strain upon the mandrel stem is changed from one of compression to one of tension.

When the tube has been drawn hot in the manner described to a certain point, it is cut with a hot saw to length, and the finishing processes are performed cold. These finishing processes are: drawing through dies several times, and annealing and pickling between after pass. The machine used is the chain draw-bench [6], which we have already seen in use for making butt-welded tubes, but the test through which the tube passes is not a screw press, but a hardened steel die. Otherwise the operation is the same as we have already seen. The tube, as drawn cold, contains a mandrel, so as to preserve the true diameter, and each die being smaller than the external diameter of the tube as it enters, elongates the tube. The annealing furnaces must be large, as they have to accommodate tubes up to 25 ft. long. After annealing, the tubes are pickled in dilute sulphuric acid, to rid them of scale. Special hammers also are usually employed to reduce the ends of the tubes for gripping in the screw clamps attached to the drawing chain. Finally, the tubes are cut by cold circular saws, and are ready for the market.

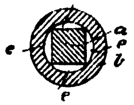


6. TUBE DRAW-BENCH

For very light gauges of tubing, such as used for cycles, the tubes are, after cold drawing, reduced further by a process of cold rolling. This operation is performed by means of two horizontal taper rolls placed side by side and tapering towards opposite directions. The tube, having inside it a mandrel fitting it exactly, is passed through these rolls, which stretch the metal, and can reduce a tube from 9 B.W.G. to 16 B.W.G.

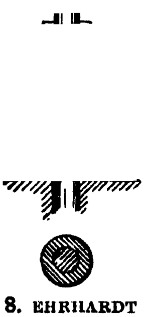
The Ehrhardt Process. In the process just described the billet is drilled when it is cold. It is also common practice to displace some of the metal from the centre of the billet when it is hot. One of the various methods may be adopted to this end. We shall describe briefly one such process. It is the Ehrhardt process, and is used in the manufacture of gun liners, shells and other war materials, as well as for making ordinary steel tubes. The process is as follows, in the words of the inventor's specification:

"To produce a hollow cylinder from wrought iron or steel, a piece of square iron or steel is taken, the cross-section of which, measured diagonally, corresponds to the diameter of the hollow cylinder to be pierced. The said piece of iron or steel [7*a*], when in a red-hot or white, glowing state, is delivered into the matrix *b*, the inner space of which also corresponds to the shape of the hollow cylinder to be produced, and a pointed core-bar, *c*, is then driven into the metal by means of a hammer or press, while the lid, *d*, is used as a guide for the said core-bar. The diameter of the latter is chosen so that the material forced aside by it is sufficient to fill the four segment-shaped spaces between the square sides of the block and the interior surface of the matrix. The core-bar enters the metal without any difficulty, as the metal, while being forced away, can give way at its sides, and a hollow cylinder with closed bottom is produced." The lower part of **7** shows a section of the square billet in the cylinder previous to the introduction of the core, and **8** shows the core, *f*, driven home, with a section showing how the billet is expanded to circular shape. The billet may be pierced from both ends as illustrated in **9**.

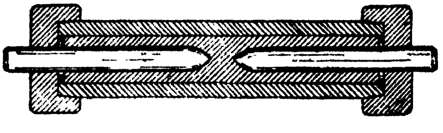


7. EHRHARDT PROCESS BEFORE PIERCING

This is the principle of the process, and we may make a brief examination of the practice. The billets used are generally of Swedish steel, and are received square, a shape which is an important essential. They are 10 ft. or 11 ft. long, and in section are from 3½ in. to 8 in. square. The billets are cut to lengths sufficient to allow sufficient metal for the pipe to be made. The cutting is done with cold saws when the sections are over 5½ in., and with hot saws when smaller than that size. The cut length at white heat is then put into a vertical hydraulic press provided with a circular die. The corners of the square billet just touch the internal circumference of the die, so that there are four segments between the die and the billet. A mandrel now descends and the billet is pierced, the metal displaced in making the hole causing the mass to expand and to fill the segments already mentioned. The mass of metal put into the die and the mandrel must be apportioned in size so that the metal displaced by the latter must exactly fill the cylindrical die at its circumference. The billet pierced in this manner is again heated, and taken to the draw-bench, where it is drawn to the required gauge. The same internal diameter is maintained from the piercing to the last drawing process, all the drawing processes reducing the external diameter by elongating the metal. When exactness of gauge and diameter is not of first importance, pipes may be finished hot. When these considerations are matters of moment

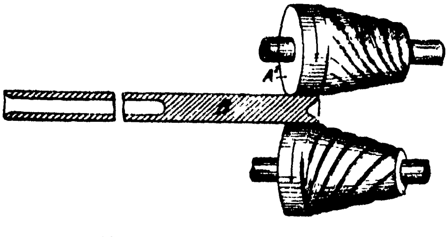


8. EHRHARDT PROCESS AFTER PIERCING



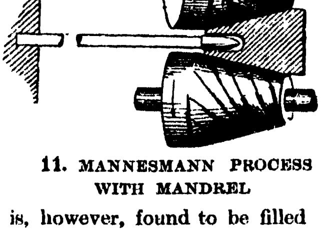
9. EHRHARDT PROCESS PIERCING FROM BOTH ENDS the final processes are cold drawing, as described in the previous process, the tubes being pickled after the hot drawing and annealed and pickled after the cold drawing.

Tubes from Cored Billets. Several processes, by which the metal ingot from which a tube is made is produced with a longitudinal hole, thereby making it cylindrical in form, have been evolved and some are in operation. In one, the core is of oblong section and is, of course, made of some refractory material such as graphite. The billet, being cast with this core is flattened, making what is in effect a flattened tube. It is then opened and goes through several modifications of sectional form, ultimately becoming round and being drawn over mandrels in the usual way. Every process using billets already cored in their first state proceeds much after the same manner.



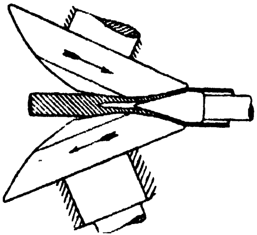
10. MANNESMANN PROCESS

Mannesmann Tubes. The Mannesmann process of manufacturing tubes from steel ingots was described at its introduction in 1890 as "an epoch-making invention." The absolute novelty of the process and the marvellous results which it gave caused experts to be sanguine about the revolution it was to make in tube manufacture. To quote the words of one of the experts who hailed it with acclaim, it "accomplishes the apparent mechanical paradox of expanding a solid block of metal into a hollow steel tube with a void within several times its own original mass, by pressure applied from the outside, and this it does with great certainty, ease, and quickness." This is really what the process accomplishes. It must be stated, however, that the Mannesmann process has not killed every rival process, and to this extent it has disappointed the great expectations of its inventors and sponsors. It is one among many good processes, not the superlative process that has superseded all others. Its chief objection is that very great power is required for the machines necessary, and this means a high expense. Of the quality of the product there is no question. It was found that a red-hot billet led between two rapidly revolving rollers [10] of conical section or inclined longitudinally towards each other — revolving in the same direction—that is, with their opposing surfaces revolving in opposite directions, as indicated by the arrows in the illustration—was made to assume a hollow shape, of tubular form. What seems to be a vacuum is created. The space is, however, found to be filled with almost pure hydrogen gas given off by the hot iron. The heated billet is placed between the rolls, being led through guides, so as to make lateral motion of the rod or billet impossible. The end of the billet that enters the rolls is slightly flattened, and this causes the particles on and near the surface to be pushed forward more quickly than the remaining parts, thereby forming a cup-like recess in the end of the billet. As the rolls keep moving, the hot metal is pulled from the inside of the rod and pushed forward in the shape of a tube. Great rapidity is essential, or the metal would become too cool for manipulation before reaching the end of the billet. As already stated, the power required for this process is very high. It varies from 2,000-horse power to 10,000-horse power, according to the diameter of the tube in process of manufacture. The revolutions of the flywheels in the machines are so numerous that such wheels are usually made of large discs inside which and around the hub wire is tightly wound to give the necessary weight. Cast-iron flywheels would fly apart, and have, indeed, done so on several occasions before they were discarded.



11. MANNESMANN PROCESS WITH MANDREL

A mandrel may be used when exactness of internal diameter is required [11] and when a tube of small diameter and heavy gauge is being made into one of larger diameter and thinner gauge. The Mannesmann process produces tubes of very high tensile strength. Figure 12 shows a different form of revolving cones.



12. MANNESMANN PROCESS

The Stiefel Process. The Stiefel process deserves mention as it has points of resemblance to the Mannesmann process. Two opposing discs mounted upon revolving vertical shafts parallel to each other and not in the same plane have faces with circumferential bevels. The hot billet is made to pass between these discs and on to a pointed mandrel placed in position, which pierces it in its progress. Suitable guide blocks are placed to keep the billet in its path.

Large Steel Tubes. Tubes of very large diameter have been made by a process of rolling subsequent to a rough drawing. The maximum size made hitherto by this process is 10 ft. long and 8 ft. in diameter, and there is no reason why the diameter at least could not be made much greater if it were desired. Such tubes have been used for rings for locomotive boilers, cylinder linings for hydraulic presses, and other purposes where high tensile strength is imperative, and where formerly the structures had to be made of plates curved and welded or riveted.

The process consists first in piercing a steel billet of suitable size into tubular form, and then of inserting a roller not shorter than the size of the tube desired, and rolling the tube already made, thereby increasing its diameter circumferentially as the shell is attenuated.

Die Press Process. Another process of tube manufacture consists in pressing discs of metal in a die press until after successive operations they evolve from flat shape to cup shape, then becoming longer, thinner, and of smaller bore under suitable pressing dies until they assume the ultimate form desired. This mode of manufacture is suitable for objects such as cartridge cases, and steel cylinders for gas, which in their final form are to have one end closed. They are thus cylinders rather than tubes. The open end is, if necessary, narrowed or closed by compression, or, in the case of heavy iron or steel cylinders, the object may be made in two halves, which come together sectionally, and are united by welding.

Lock-joint Tubing. Various attempts have been made to manufacture lock-joint tubing, and the problems involved present no great difficulties. The usual practice is by rolling processes and through formers which bend around the edges of the strip into suitable shape, so that one edge may engage the other. Then the edges are brazed or soldered [see Soldering]. The manufacture of such tubing is limited, and is seldom used for making iron and steel tubing.

Taper Tubes. For some purposes taper tubes are desired. In the case of locomotive boiler tubes, for instance, they may be made parallel outside, but tapering inside, and therefore of heavier gauge at one end than at the other end. This is done in order that the thicker end may be placed where it is subject to greatest heat, and the thin end where the heat is less intense and the thickness superfluous. Brass and copper tubes are made with an internal taper by drawing them upon a taper mandrel the entire length of the tube, and by stripping them from this mandrel. Iron and steel tubes with internal taper are made by different processes. Ricketts' method provides that, in the process of drawing tubes through dies and over a bulb-headed mandrel, the mandrel should be made of slightly tapering form, and should have a very slow longitudinal travel, working automatically after the manner of the automatic feed on a drilling machine. Thus the space between the mandrel taper and the die, which space decides the gauge of the tube, is gradually widened, thereby producing a tube of gradually increasing gauge, and therefore with internal taper.

Heavy iron and steel tubes, such as are used as standards for electric lights and for electric railways are made by using as a die a pair of rollers provided with circumferential grooves with gradually increasing sweep. These rollers revolve in unison, and as they do so the die formed by the two grooves, while always remaining circular, increases in size, thus making the tube taper.

Annealing Tubes. In drawing tubes cold through dies as in wire drawing, the drawing process hardens nearly all metals, rendering them incapable or extremely difficult of further drawing and to reinvest them with the necessary ductility annealing is necessary. The annealing chambers, as we saw in considering wire drawing, are simply ovens of suitable size, and into these the articles are placed and maintained at a high temperature. Annealing, under the usual conditions, demands that the object annealed should be afterwards "pickled"—that is, immersed in a solution of hydrochloric acid (usually one part to 39 of water). This pickling removes the oxide of iron which the annealing has caused to appear on the surfaces of the tubes. Many attempts have been made to dispense with the necessity for pickling, and what is termed "bright annealing" is a not uncommon process. In bright annealing, the articles in the annealing ovens are annealed not surrounded by air as in the common process but by some gas which does not have the oxidising influence of the air. In some cases the annealing oven is put into communication with a coal gas supply service. By admitting the gas the air is expelled and the articles are then annealed without the formation of scale, maintaining their original brightness.

Other devices adopted include special methods of pickling. One process attempted removes the scale electrically by making the tubes anodes in an almost neutral bath, and by introducing lead or iron plates as cathodes.

Brass Tubes. The production of brass tubes is very large. Such tubes were formerly made by the primitive hand method, in which a strip of sheet metal was cut to the necessary width and bent around an iron rod. The edges of the partially-formed tube were then bound together with rings of wire, solder and borax were placed along the seam and fused in a common forge or under a blowpipe. Then, after being soldered, the tube was hammered round the rod upon which it had been formed, fullers being used in the process.

The present-day process of making tubes of brass and other metals gives results much better than the original method mentioned. Strips of metal of a suitable width are cut. In the case of large tubes demanding thick sheets the strips are put longitudinally through rolls—one concave and its fellow convex. By this device the strips are made into long channels the section of which is curved. Then, by beating it with a hammer, the end of the tube is tapered. The drawing tool is placed in position in the draw bench, and the tapered end, or tang, is passed through it. The draw tongs are made to grip the latter, and put into motion by means of the chain, which drags them along the bench, pulling the metal strip through the dies, and giving it the form of a tube with a seam up one side. Then the *wirer*—that is, a workman, or often a workwoman, responsible for the next operation—binds the edges together by encircling the tube with rings of iron wire at a distance of 2 in. apart. Then another operator, called the *charger*, places along the seam some *spelter*, or brass solder, in granulated form and mixed with borax.

The crude tube so prepared is now placed in a soldering stove, which must be of a suitable length. When it has been raised to a red heat, the brass solder and the borax fuse and unite the two sides, making the tube complete except for the finishing processes.

The binding wires are removed when the tube has cooled, and the surplus solder is removed by filing or grinding. Then pickling in weak acid cleans off the adhering dirt and the tube is again passed through a die on the draw bench. If a tube of absolute accuracy—internally, as well as externally—be demanded, a smooth mandrel is placed inside it before it receives this final drawing, and the drawing die, offering pressure to this resisting mandrel, makes a tube smooth in surface and uniform in gauge both internally and externally.

Solid Drawn Brass and Copper Tubes. The ingot which is to make brass or copper tubes must be carefully made, and certain precautions are necessary. It must be sound metal, and must have a sound face, or the chance of a good tube resulting is small. Clean metals poured into warm moulds should give the desired result. If the moulds are cold, and the cores warm, the latter will draw moisture, giving unsound ingots, in addition to which there is a danger of some of the metal blowing out of the mould. Usually, the casting is done in iron moulds set vertically and with warm cores. Mould and cores should be coated with plumbago or chalk, the former for preference.

Welsh coke is the best fuel, but if gas coke be used, it should be clean, or impurities may be carried into the metal.

With alloys of zinc, the heat should not be raised too high, or the composition of the alloy may be altered somewhat, and if exact specification be demanded, this may be bad. The flux used in making alloys must depend upon the constituents of the alloys, but it ought to produce a metal in a clean fluid state, and with melting temperature as low as possible.

A little lead, especially if it contain a percentage of silver, will make the process of rolling and drawing much more easy, and it is worth adding, but only a small quantity will enter into the alloy, any excess above this quantity squeezing out in cooling.

The hollow ingot, having been cast, is placed upon a mandrel and pulled through successive dies, each smaller than that preceding. Sometimes the mandrel is stationary as well as the die, and the tube is drawn between the two. Between each drawing the tubes are annealed and pickled, this being necessary to re-impart the ductility required.

Copper Tubes by Electric Deposition. Copper tubes are made by electrolytic deposition as well as by the mechanical process described. The chemical purity of electrolytic copper is well known, and when the plant is arranged to deposit the copper in the form of a tube there is a great saving of mechanical operations. Tubes made by this process are able to stand very severe tests. They may be doubled close cold and then doubled over; they may be doubled close cold and then opened out, and they may be expanded and flanged with a flange three times the diameter of the tube—all without splitting or showing defects.

In the process of manufacture the copper is deposited upon a mandrel. For tubes up to 4-in. inside diameter the mandrel is of brass, and for larger sizes it is of cast iron, with a brass neck to take the current. The cast-iron mandrels, previous to use in the tube depositing tanks, are immersed in an alkaline electrolytic bath, containing sheet copper anodes, where they receive a thin covering of copper. The alkaline bath is kept at a slight heat. All the mandrels, whether of brass or of cast iron, are covered with plumbago, so that the finished tube may be easily removed after deposition.

The anodes used in the depositing bath are made from copper bars, which have been refined to remove arsenic and other impurities, and are practically pure copper. They are cleaned with diluted sulphuric acid before immersion in the depositing tanks. In operation the copper anodes and the mandrels are placed in the tank, the latter nested alongside of the anodes and resting on insulated supports at both ends. Acid sulphate enters the tank by gravitation from suitable reservoirs. The positive current reaches the copper anodes through lead conductors, and the negative current reaches the mandrels through copper conductors and flexible brushes. The mandrels revolve during the process, while agate burnishers travel along the whole length, giving to the tube uniform density and a surface of mirror smoothness. The coated mandrels after removal from the tank are treated in a tube expanding machine, and in a power draw-bench, which pulls the tube from its mandrel. Sometimes the tubes are subsequently drawn to different dimensions to those in which they leave their mandrels, and in this event they must be afterwards annealed and pickled

Aluminium Bronze Tubes. Aluminium bronze is specially suitable as a material for tubes, for water-tube boilers, condensers, and acid industrial works. Its ability to resist corrosion is excelled only by gold and platinum, and its electric potential is almost nil. Aluminium bronze tubes are of en drawn by the Mannesmann process, already described. To attempt to draw them on draw benches commonly used for drawing brass and copper tubes is to spoil the dies, which are not strong enough to resist the hardness and high tensile strength of the alloy. During the process of drawing, aluminium bronze tubes require frequent annealing.

Brass-cased Tubes. Much of what looks like brass tubing is only iron tubing covered with brass. Great economy is effected by substituting this so-called *brass-cased* tubing for solid brass tubing. Instances of its use are brass bedsteads and brass curtain poles. The latter are usually, however, of brass entirely when they are bent to fit oriel windows. The methods of making brass-cased tubing is ingenious and simple. The iron tubing is made from hoop or strip iron in the manner we have already described except that the butting edges are not usually brazed, welded, soldered, or otherwise joined. Then a tube of brass larger in its internal diameter than the external size of the iron tube is made in the same manner. The iron tube is put within the brass tube. It enters easily, being smaller. Then the two together are put on the draw bench and pulled through the die, which compresses the brass tube in diameter and extends it longitudinally. This mere pressing of the brass tube upon the iron tube gives sufficient adhesion for all purposes to which brass-cased tubing is usually put. Sometimes the brass tubing is brazed before being drawn down on the iron tube, but for some purposes this is not done. If we examine the brass-cased tube that serves for the head rail in a cheap iron bedstead, we shall probably find that the underside shows a seam. This is because, for considerations of price, the brass tube has not been brazed at its edges.

Tubes of Odd Section. Tubes of odd form, such as square, oval, D-shape, triangular, fluted, or polygonal, are made simply by making the drawing die and the mandrel the necessary shapes. They present no difficulties greater than those in drawing ordinary round tubing. When tubes other than round are desired to be made with their section spirally to the length, making thereby what are called *twisted tubes*, the tool through which they are drawn, in addition to being of the desired form, is made to revolve. It is geared to the wheels that operate the drawing mechanism, and thus a uniform number of twists can be given throughout the length of the tube. The tool in this case really acts like a screw-plate, putting a thread on the tube pulled through it. Many forms of ornamental tubing, such as are much used for gas pendants and other gas fittings, lamp standards, etc., are made by passing brass tubing through hard metal rollers containing grooves cut with the desired pattern. A solid brass tube is supported inside with a mandrel, so as to offer resistance to the pressure of the rollers, and by passing tube and mandrel through the machine the desired design is imparted to the tube.

Lead Pipe. Lead pipe, or pipe made of an alloy of which lead is the principal constituent, and termed *compo* pipe, is used largely in domestic plumbing work. The former practice of making lead pipes was to bend strips of lead round a mandrel and to solder the edges together. Such a practice has long been discarded, except where the small plumber makes his own traps, and pipes of lead are now forced by pressure through a hole or die the size of the external diameter of the pipe being made, and having in its centre a mandrel the size of the internal diameter of the pipe required. The power used is usually hydraulic, and the machine is a hydraulic press. The usual charge of lead is between 2 cwt. and 4 cwt., and this is poured in a molten state into the chamber. Pressure is applied before the lead has quite cooled, so that it is to some extent plastic. Sometimes a furnace surrounds the chamber, so as to keep the lead at its proper temperature as the pipe is being made. The smallest size of lead pipe—$\frac{3}{8}$ in.—is usually made in from 30 to 40 yard lengths, and large sizes —from 2½ to 6 in.—in 12-ft. lengths.

Extruded Tubes. An account of tube manufacture would be incomplete without notice of tubes produced by Dick's extrusion process, which is worked by the Delta Metal Company. It is really the process used in manufacturing lead pipe, by pressing it through a die applied to working alloys in a molten state. The machine which is called into use consists essentially of a cylinder and a hydraulic ram. The heated metal, usually an alloy of copper, is poured into the cylinder, at one end of which is the die. Upon the application of pressure from the opposite end, the plastic metal issues through the die as a rod or tube, conforming in section to the shape of the die. The chief use of this process is in making bars or rods of odd sections, which could not be rolled; but many articles of tubular formation are also made. In their case, a mandrel is placed within the die, and this gives the form to the internal diameter of the article to be extruded. Successful operation of this process is due to the fact that the alloys that are treated may be separated into more than one stream when in a plastic condition, and will reunite readily and perfectly under simple pressure if no air has been admitted to oxidise the fresh surfaces created. This separation takes place in the cylinder, because the metal is broken into two or more streams as it passes the arch that holds the mandrel in position; but a reunion takes place before the metal comes to the die. Alloys of copper are usually extruded at the temperature of plasticity, which is about 1,000° F. For small work, the cylinders are fitted with several dies—up to four in number—and four tubes or rods are produced simultaneously.

Flexible Metallic Tubing. The desirability of having flexible tubing much stronger and more durable than is possible with indiarubber admitted flexible metallic tubing into immediate favour, and new spheres of usefulness are continually being found for it. It is made by the United Flexible Metallic Tubing Company, Limited. It is largely used in railway work for water-fed pumps from the engine to the tender and for heating carriages. In countries of extreme temperatures, that cause rubber to perish within a short time, flexible metallic tubing is extremely valuable. Rock drills actuated by compressed air often have the air supplied to them through this variety of tubing with excellent results. It has also been used to pump liquid fuel in the form of petroleum from one vessel at sea to another while both were going ahead at almost full speed, thereby saving a good deal of time in ocean voyages. These are merely a few of the many uses to which flexible metallic tubing is now put.

The process of manufacturing flexible metallic tubing demands great care, and the resulting tubing must fulfil two conditions—it must be flexible and it must be water and air tight, even, in some cases, under high steam pressure. It would be easy to make it flexible at the expense of the latter quality, and it would be easy to make it airtight at the expense of flexibility. To serve its purposes, however, it must have as much flexibility as is consistent with absolute airtight qualities.

Making Flexible Metallic Tubing. The first thing necessary in manufacturing the tubing shown in 13 is an extremely tough, and, at the the same time, highly ductile metal strip or ribbon of absolutely uniform width and of very great length. This ribbon—of steel, brass, copper, zinc, or, indeed, any metal sufficiently ductile—is drawn through successive formers, which gradually shape it from the flat strip into a sort of double tube having the section of the figure 8, only the ends turned over do not butt close up to the central web. The final process is that of coiling this strip in a spiral form round a core, causing the lower part of each spiral to engage the upper part of the spiral to which it is united, thus forming the tube. In this operation the tension of the strip, the accurate adjustment of the metal surfaces, and the mode of release from the core or mandrel upon which the tubing is made, are the matters of chief moment. All these operations are accomplished in a single machine, which receives the plain metal strip and delivers the tubing complete and ready for use. Very long tubes can be made by the process described, the length being limited only by the limitations of the strip that can be supplied to the machine. Thus, to make a tube $\frac{3}{4}$ in. in diameter requires strip $\frac{8}{10}$th millimetre thick and 14 millimetres in width, and the limits of length for metal strips of this section is from 6,000 ft. to 7,000 ft. It requires 10 ft. of strip to produce 1 ft. of tube, and this gives 600 ft. to 700 ft. lengths of tubing of the size mentioned. When tubing is required in greater length than this, these long strips are united by electric welding, so that there is no practical limit to the length that may be supplied in one piece.

13 FLEXIBLE METALLIC TUBING

For steam purposes, flexible metallic tubing is made of copper, pure or alloyed; for use in pumping oil, and other purposes, steel is used; brass tubing is provided for locomotive work, and for use as gas tubing in making flexible connections, both steel and zinc are employed. For suction as well as for use under compression, this tubing is excellent.

Gas Fittings. An important use to which tubing is put is the manufacture of gas fittings. Into the many forms of gas fittings space will not permit us to enter. We can record only the present tendency of the trade. Undoubtedly the invention of Auer von Welsbach—the incandescent gas mantle (see GAS)—gave to gas lighting a hold which it was gradually relaxing, and postponed the general adoption of electricity as a domestic illuminant. The tendency of taste in modern gas fittings is away from the sliding water-sealed chain and weight gaselier towards fixed pendants and brackets, and to pendants that can be raised and lowered without a water-sealed tube. The popularity of the inverted gas mantle is creating a demand for new styles and new designs in gas fittings, and at present there is no evidence that fixity of design has been attained or that the problems of construction have been properly solved.

In gas fittings, soft or tinman's solder is avoided, and hard soldering or brazing is adopted. Ornamental tubing such as we have already noted is used extensively for gas fittings, but even here there is a distinct tendency towards plain, round tubing, and to lightness and grace contrasted with ornament and elaboration. Mountings of gas fittings are to a great extent stamped brass work. Taps, swivels, and couplings are, of course, cast brass, and are made chiefly by semi-automatic machines. Ingenuity is being exercised in the finishing of gas fittings, and fashion, to some extent, holds sway here.

Tube Bending. Cast-iron pipes, of course, cannot be bent at all. Wrought iron and steel tubes are often filled with sand, heated to redness, and bent round a shape, the welded side being kept at the inside of the bend. Brass tubes for curtain-poles and other purposes are filled with pitch, and, when cold, bent round something of a suitable shape. Then the tube is heated, and the pitch re-melted and poured out. This demands that the tube must be repolished. A coil-spring mandrel is also used for bending tubes for cycle and other work. The mandrel is screwed up to its minimum diameter and inserted into the tube. Then, by turning a key at its extremity, it is distended inside the tube as far as the internal diameter of the latter will permit, and the bend is made, the mandrel resisting the flattening at the bend which would otherwise take place. The mandrel is again screwed up tightly and withdrawn. This method cannot give very sharp bends, and the spring mandrels are expensive and somewhat brittle.

14. KENNEDY'S TUBE-BENDING MACHINE

Some machines have recently been invented for the purpose of bending tubes, and perhaps the best is Kennedy's patent [**14**], which is now used by several Government departments. It consists essentially of a circular plate grooved on its periphery to suit the tube to be bent. A plate of the proper size is placed on a vertical centre, and a hard steel grooved block, mounted upon a lever and made to describe an arc parallel to the periphery of the plate, is pressed against the outer side of the tube, thus making the bends. By a sufficient number of grooved discs, and a machine of the proper capacity, this machine gives a very wide range of bends that may be made and sizes of tubes that may be handled. The weld—if the tube be of the welded variety—should be on the inside of the bend. In the largest size, the power is applied manually by a worm and wheel arrangement.

Measurement of Tubes. The measurement of brass and copper tubes is calculated upon the outside diameter, and tubes of iron, steel, lead, and composition, or *compo* tubes or pipes, by the inside diameter. The reason for the apparent anomaly is that brass and copper tubes are used largely for purposes where the external size is the important consideration, and that the chief purpose of the tubes of other metal is to pass water, gas, or steam where the quantity that the pipe or tube will take is the important point. The result of this method of calculating size is that tubes—say, ¾ in. diameter—for gas, water, and steam respectively—look very different from each other in external diameter.

It is the practice of most tube-makers to manufacture welded tubes for water one gauge thicker than gas tubes, and steam tubes again are one gauge thicker than water tubes. The usual gauges, thicknesses, and weights of the three varieties of tubes and the number of threads per inch in the screws used for them are given in the table that follows:

WROUGHT-IRON TUBES FOR GAS, WATER AND STEAM

Bore in Inches.	Screw Threads per Inch.	GAS			WATER			STEAM		
		S.W.G.	Thickness in Inches.	Pounds Weight per foot.	S.W.G.	Thickness in Inches.	Pounds Weight per foot.	S.W.G.	Thickness in Inches.	Pounds Weight per foot.

HOW TO LINE HAT BRIMS

Preparation of Hat Brims for Fancy Linings. Velvet Binds and Crossway Folds. Preparing and Joining the Material. Making and Sewing in Bandeaux

By ANTOINETTE MEELBOOM

DIFFERENT kinds of binds may be used to make brims more becoming to the face of the wearer, and also to form part of the trimming of the hat. Before a rouleau, velvet bind, or French fold can be sewn to the hat, the brim must be prepared.

Remove the wire already on the hat, as it is generally too thick and will cause the rouleau to stand out from the brim too much; and, secondly, it is very often of inferior quality, and is sewn on with stitches so far apart that it does not answer the purpose for which it is required—that is, to keep the brim in shape. A strong fine silk support wire to match the straw or felt is substituted, and, in the case of a straw hat, is sewn on the width of one straw in from the edge.

With open fancy straw it must be sewn on the part sufficiently strong to hold the stitches. Use wire stitch, and allow 2 in. on the wire to cross at the back [106]. The stitches must exactly fit the wire, and not be too far apart, or the wire will not set well round the curves. Contract the wire slightly for a turned-up brim.

Pin on the rouleau with lillikins, or steel pins, over the wire [105], stretch it slightly, cut away what is not wanted, allowing ½ in. for turnings for the join. Undo the fold for a few inches on either side, and join on the cross [114].

If there is already a join in the rouleau, see that the joins slant in the same direction, and herringbone the edges together again. Pin in place and slipstitch it to the hat just above the wire all round. The rouleau should lie quite flat, and no stitches must show on the right side. Felt hats are prepared in the same way, except that in smooth felts the stitches must not be taken through the brim, but only through half the thickness of the felt. Use a very fine needle and cotton. Felt hats are often wired at the edge, mulled, and trimmed with a velvet, silk, or braid bind.

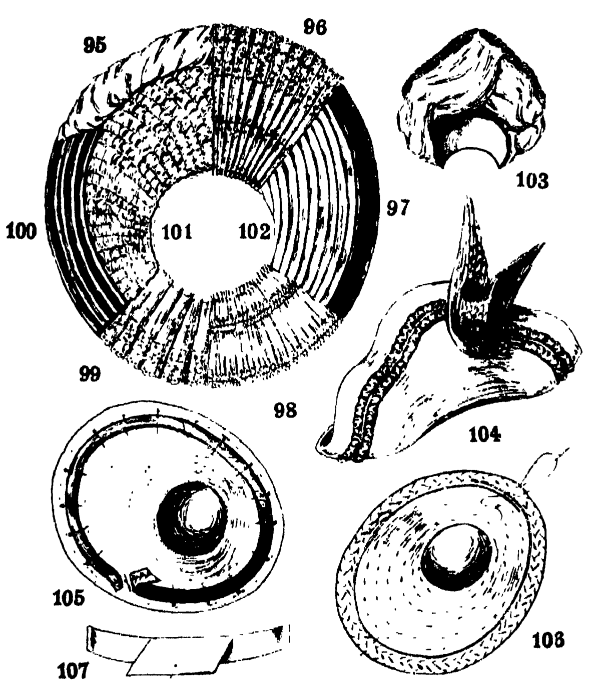
Velvet Binds. For a velvet bind [97], measure round the edge of the brim. Most brims require one and a half to nearly two crossway lengths of velvet about 3 in. wide. Shade and join the velvet. Pin it on the hat and join in a round. Press the seams. The joins are very difficult to manipulate and show the difference between amateur and professional workmanship.

Stitch it in on the outside of the hat with long backstitch, the right side of velvet to upper side of brim. Turn over carefully and turn in the raw edge with the needle—on no account use the fingers, which would stretch the edge of the velvet. In boat-shape, French sailor, or similar turned-up brims, the bind, if carefully put on, will keep in place on the outside without any other stitching. For curved or fluted brims, the bind must be slipstitched on the underside, in order to set it in the curves. A corded or plain ribbon bind to a felt hat is evenly stitched with twist, the same size stitch showing on both sides of the brim.

Another effective way of trimming the edge of the upper and under brims is by narrow crossway folds in velvet or silk [100], the fold of each row overlapping the raw edges of the previous one, the last being finished with a rouleau or French fold.

For a wide velvet or silk bind of 1 in. or more wide, on either side of the brim, measure round the edge, join the material in a circle, and press the seams.

Fold the velvet in the centre, stretch the centre of the fold with the blunt end of the scissors; be very careful only to stretch the *centre*—not the cut edges. Place this on the

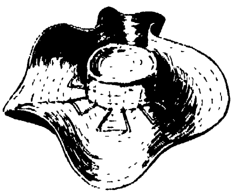


95–107. HAT-BRIM LININGS

edge of hat, turn in the raw edges, and slipstitch top and bottom, being careful not to draw the velvet.

Full gathered or rucked edges on hat brims in either velvet or silk are made of crossway pieces, in length twice and a half times the circumference of hat, and about 3 in. wide. Join them in a circle, mark the half and quarters also on the hat brim. Regulate the fulness evenly, and secure the material by the long backstitch to the brim, along the gathering thread. Turn over the velvet and slipstitch down to underside of brim.

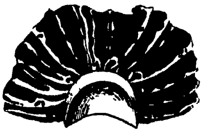
A much softer effect is obtained by not pulling the fulness tightly over the edge; also by regulating the fulness *diagonally* over the edge before slipstitching it to the under brim [**95**].



108. WIRING "FLOP" BRIMS

A cord run in a velvet tuck at the edge of velvet, drawn up to size of edge of hat, sewn on, the underside turned in and slipstitched as explained before, is another pretty finish [**104**].

Satin wires used on felt, velvet, or straw hats are slipstitched to hat brim, the stitches taken through the underside of silk filament of the wire, to prevent them showing when the hat is worn, and through half the thickness of brim in felt.



109. VELVET BONNET LINING

For joining at the back, side, or wherever the trimming is likely to come, carefully undo the silk filament at each end; cut away some of the cotton covering which is underneath, overlap the two wires for 2 in., twist the cotton covering round them, and wind round the silk filament again very gently. If carefully done, the join will be invisible. If two wires are to be placed very close to one another, there is no need to finish each round; the first one may be taken on to the next.

Crossway folds of silk or chiffon [102] for hat brims are cut 2 in. wide and joined in one length. Tack the edges together. Straw, felt, and velvet brims must first have a facing of mull, leno, or silk. Start from the outside edge, avoiding any joins showing in front of brim. Arrange each fold separately, *slightly* stretching the outside edge. Stitch each row in position, hiding the stitches of the previous ones.

Chiffon Linings. Gauged chiffon linings [**98**] take from three to four and a half times the circumference of brim; of fine tulle even six times, and the depth, plus as many tucks as required, is not too much to obtain a good effect.

Mark the half and quarter of the length, run three or more tucks at the edge; pin, and sew on hat just above the wire. Make more tucks, regulating the distance according to the shape of hat brim. Pleat evenly in the headlines.

Plain tucked chiffon linings are made with the tucks about ⅛ in. to ¼ in. wide, each just overlapping the other. The tucks are usually run selvedge way, but they may be made on the cross. Slipstitch round the edge of brim and gather the fulness in the headline. Chiffon or silk may be gauged diagonally [**101**]. Draw up the gathering threads. Ease on round edge of brim. Cut the silk on the cross one and three-quarters the depth of brim, and one and a half times the circumference.

Pleated lace linings [**96**] have a tiny stitch taken *on* each pleat.

Fluted lace linings [**99**] have a tiny stitch between each pleat, and the lace is pleated evenly in the headline.

Beads are sometimes used as trimmings. They are threaded on fine wire and sewn on with a stitch taken through the bead into the shape. The wire should be held firmly with the left hand.

Soft felt, straw flop, or capeline hats [**108**] are wired round the edge. These shapes also need four extra wires to give support to the brim and crown. The wire is run for about 1½ in. to 2 in. in crown. These are also wired round headline, or a band of net or buckram wired top and bottom may be used. For deep crowns, a separate wire foundation must be made.

The wiring of brim is done either underneath or on the top, according to whether the brim is to be turned up from the face or not. If wired on the outside, the trimming will in most cases cover it.

Bonnet Shapes. Nearly all bonnets have full or rucked edges which make a becoming front trimming for the face. There are two kinds, either for the open front or the close-fitting bonnet.

For the open front [**109**] a full velvet lining is often necessary to fill up the space between the bonnet front and the head.

For the close shape [**103**] a rucked edge is used to take away the hardness of the shape.

For the open front, measure the depth of the centre-brim and allow half as much again for fulness. Measure the outside edge of brim and allow half to three-quarters as much again for fulness.

If one length of velvet is insufficient, add on narrow pieces each side, as a bonnet brim is always much narrower near the ears. If a longer piece is necessary, join the piece on either side and cut afterwards in the middle of the narrow part [**107**]. Mark centre-front and gather each edge. Prepare the bonnet edge in the same way as the hat brim is prepared for a fold.

Place centre of velvet lining to centre of brim. Arrange most of the fulness in centre-front, lessening it gradually towards the ears. Backstitch the velvet on closely, just above the edge wire on the line of running stitches. The lower edge is stitched round the head and the velvet arranged in light puffs with the point of the needle.

For a "rucked edge," the measuring, cutting off, and preparation of velvet are the same as just explained, the only difference being that the velvet is not usually stitched on the edge of the bonnet, but about 1 in. to 2 in. *above* it.

The needle should never be put through the double pleat of the velvet; it should be brought back close to where it went in and the cotton tied. Lightness of touch, to use no more stitches than necessary, and never to draw the fulness tightly over the edge, are points to be remembered. The bonnet should next be headlined.

Preparing the Velvet. Velvet is a rich-looking fabric whose chief characteristic is its *pile*, or raised surface. It has a short surface which, in coming from the loom, is pressed slightly in one direction, thus casting a shade, and giving it a darker tone against the pile than with it. Experienced fingers can feel the way the pile lies, it being smoother in one direction than the other. The better the quality of the velvet, the more distinct is the shade. In correct shading lies much of the difference between amateur and professional work. Hold the velvet to the light, and, before joining or cutting out, see that the pieces shade the same way.

Three kinds of velvet are in general use—the silk, the patent, and the cotton back. Velveteen is too heavy, and is used only occasionally to match children's Liberty coats and pelisses. The silk-back velvet is manufactured entirely of silk filaments; it is very light, has a close pile, keeps its colour to the last, renovates well, and is always used for the best class of work. Its price is from 7s. 11d. a yard. It wants careful manipulation, as the lightness of its pile causes it to be easily plushed or flattened.

The "patent-back" velvet is a mixture of cotton and silk, but it is easily distinguished by its highly-glazed back. In the best qualities it can be mistaken for silk velvet. Its price is from 3s. 11d. upwards. It is much in use and can be obtained in a wide range of colours.

In cotton-back velvet, as its name implies, the pile alone is of silk. It is of much more open texture, soon fades, and is heavier to wear. It is only used for very cheap millinery, and costs from 1s. 11d. Miroir velvet, of the same quality, has a much better appearance because the pile is flattened down uniformly and prevents the foundation showing through the pile.

Several other kinds of velvets are used, such as panne, chiffon velours, terry, caracul, shot, plissé, corduroy; but these are only passing fashions, and their use for trimmings or coverings at once dates a hat or bonnet.

If required for trimmings only, buy the velvet on the *cross*. For covering hats it should be bought on the straight. A *corner of velvet* is extremely useful for toques or bonnets.

If we have a length of velvet on the straight, before we can cut crossway widths for trimmings, a corner must be cut off. Place the velvet on the table with its pile uppermost, and the fold *from you*—this is important. Fold the two faces of the pile together when they will not want pinning. Take the right-hand lower corner, A, of the cut edges to the selvedge of the opposite side, B. The two selvedges must be exactly at right angles. Then cut through this fold. Any length corner can be obtained by folding the velvet as from C to D instead of from A to B [110]. The extra length obtained along the top is short at lower edge [111].

A corner of velvet, it will be seen, is a shaped piece with one side on the straight and one on the cross. In covering and trimming bonnets and toques pieces can be cut from the crossway side for the trimmings, while the corner and straight part are used for covering or draping the bonnet or crown.

To cut a crossway width [112], measure the length required first along one selvedge and then along the other; snip the velvet at those points; fold it over—from you—and cut off. Be very careful that the velvet is really cut on a true cross; if there is the least inaccuracy the folds, rouleau, or trimming will not lie well and the material will be wasted.

A crossway length will measure one-third less *through the centre* than along the selvedge, and allowance must be made for this when estimating quantity required. By "through" is meant through the cross—as opposed to along the selvedge. This should be noted as the word will be so employed throughout this course.

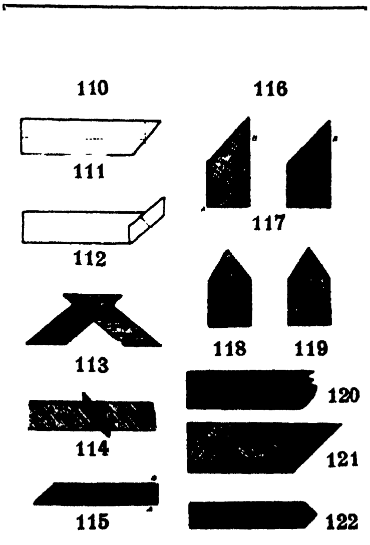
Joining Velvet. To join velvet [113] shade the velvet correctly, place the two piles together, leaving a little triangle at each edge [114]. Backstitch them with fine cotton and needle—the stitches must be quite close and tight so that there may be no gaping when stretched.

To straighten two crossway lengths for trimming, shade the pieces and join. Cut off a corner [115] and join it to A B.

To straighten one crossway end, fold A to B, stitch it and cut [116].

Trimmings and bows are frequently made of crossway widths of piece velvet. After joining the length, the raw edges must be hemmed, which can be done either by turning in the edge once, as for twists, knots, etc., or turning in the edges twice for the loops and bows, and making a narrow roll hem. In the latter case a fine wire may be inserted in the hem.

Ends of crossway pieces can be used up in making ends and ears. Ends, if faced with velvet, must be stitched along



110-122. PREPARATION OF VELVET FOR TRIMMINGS the straight side and slipstitched along the crossway side. They do not set well if not treated in this way. Pull out the point from the outside with a fine needle. In stitching do not pull the cotton tightly. Stitch as from A to B [117]; slipstitch from B to C. Always stitch for 1 in. round the point at B.

An ear is made by the long point being turned back pile to pile and stitched [118]. Turn out and hem along bottom edge. For unlined ends and ears the edges must first be roll hemmed [119]. Ends and ears may be lined with a contrasting colour of velvet or silk, joined in the same manner as described above. How to wire ends and ears is dealt with later.

For a velvet fold or rouleau, cut crossways a piece twice as wide as required, turn down each side, so that the cut edges just meet in the centre, and lace-stitch the two edges together. Another method is to slightly overlap the edges and hem as for velvet. Do not cut the rouleau too wide or it will not set well.

For a French fold [120], cut material three times the width of the required fold. Fold it in three, one cut edge inside and one outside. Turn down the outside edge and slipstitch it, being careful the fold does not become twisted.

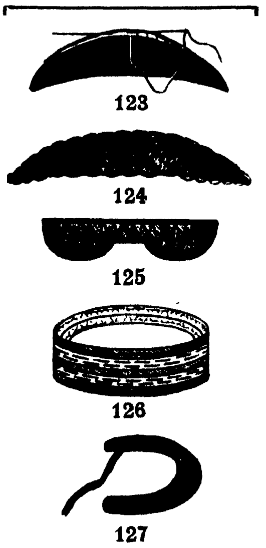
Velvet Bonnet Strings. Ladies sometimes prefer piece velvet bonnet strings to ribbon, because it may be impossible to obtain ribbon velvet to match, and they are warmer to wear, and more becoming.

Cut three times the width required when finished. Usually two widths 2 in. "through" are needed. Shade the pieces and join. Make a cravat end [121], and slipstitch as for French fold. Place the fold exactly opposite to the point of the cravat end. The strings should be about ⅝ in. wide when finished.

Another way is to hem a long piece of cross-cut velvet, make the ends up in bows, and tie under the chin. The width is a little narrower than the ⅞ in. ribbon velvet usually sold for bonnet strings because it is thicker. Piece velvet bows are made of velvet cut on the cross. The widths should be joined in one long length, and the edges roll hemmed.

Bandeaux. The style and fit of a hat depend frequently on the right shape of the bandeau, which gives it the proper tilt on the head. When it is made, pin it in, trying different positions till the right one is obtained. Often a hat does not suit because it needs a bandeau, or because the bandeau is in the wrong place.

Bandeaux vary in size and shape, and are usually covered with velvet, which clings to the hair and helps to fit the hat. They are used for these purposes: To tilt a hat at front, side or back; for sewing trimmings underneath; or to make a faulty headline either larger or smaller.



123–127. HAT

In form they are either *shaped, round,* or *straight.* Shaped bandeaux for front, side, or back, are made of spatrie or buckram; for light hats, such as chiffon, lace, tulle, of double stiff net. Round and straight bandeaux are made of stiff net and ribbon wire.

First cut out the shape in buckram and wire it with firm support wire [124]. Start wiring in the centre of the straight side of the bandeau and allow 2 in. for overlapping.

Mull the edge. Cover it with a crossway piece of velvet, placing the straight side of bandeau to crossway part of velvet [123]. Pin it in place. Cut to shape, leaving ½ in. turnings round curved part. Turn in and slipstitch, cutting the bandeau in shape as it is worked.

Bandeaux for back of hat [125] must be covered in two parts. Cut the velvet to shape, leaving ½-in. turnings. Tack one piece, turning the edge over all round, and catch-stitch it to the spatrie. Pin on the other piece of velvet, turn in the edge, and slip-stitch all round.

Net bandeaux for light lace, net, chiffon, etc., hats are made of double stiff net, wired all round, with support wires inserted between the two thicknesses of net, and nipped securely over the edge. These are covered with one or two thicknesses of tulle or chiffon, and bound with sarcenet or narrow velvet ribbon [127].

Shaped, all-round bandeaux are made of support wire to given measurements in the same way as wire shapes are made. These may be covered with straw or velvet, and, for a very deep shape, only the outer side need be covered.

Round bandeaux [126], used for reducing size of headline, should be made in this way: cut four thicknesses of stiff net, about 1 in. wide, and in length ½ in. smaller than headline; allow 1 in. extra for overlapping. Stitch two rows of ribbon wire to the net, wrapping over the ends of wires 1 in. where they join. Cut a crossway piece of velvet three times the width of the net bandeau. Turn in upper edge of velvet, bring up the bottom side with the raw edge turned in, and slip stitch.

A straight bandeau is made in the same way, except that the ends are not joined. Turn over ribbon wire for ¾ in. each end. Cover with velvet, oversewing the raw edges closely, without turning them in.

"Chip" bandeaux are mostly used for fronts of open-fronted bonnets, and are made about 11 in. long, wired all round. Stretch the chip along the outer edge and contract along the bottom edge. At each end, turn it into half its width.

To sew the bandeau to hat, pin it in the right position. Use strong cotton and the long backstitch, keeping the long stitches on the outside of the bandeau. Catch the bottom wire of bandeau to the headline or brim of hat.

THE TREATMENT OF RIVERS

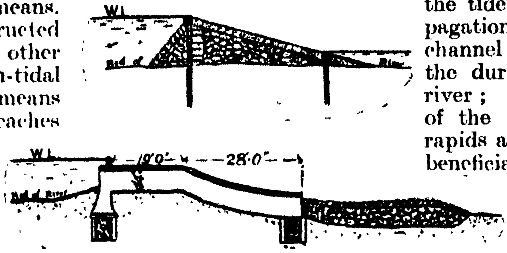
Hydraulic Works on Tidal and Non-tidal Rivers and in Estuaries. Training a River. Systems of Dredging

continued from page 5116

By Professor HENRY ROBINSON

STEVENSON has given the chief engineering works that are necessary for the improvement of rivers to assist navigation—in the non-tidal part the construction of weirs to dam back the water, thus forming stretches of canal; in the tidal branches, the straightening, widening, and deepening the beds, and the erection of walls for the guidance of the tidal currents; in the seaward part, the removal of bars and shoals.

Careful consideration must be given to the material of the bed in order that it may not be eroded by any increased velocity, unless that is the object to be attained. Care must also be taken that the works carried out on the tidal portion do not interfere with the discharge of the non-tidal part, as the result would be the flooding of the land in the upper reaches in time of maximum discharge. In large rivers (such as the Mississippi) the difficulty is not so much the decrease in depth due to the minimum flow, as the control of the water in times of flood, to prevent damage to the land adjoining. In this country, the rivers are not of sufficient size to make the work in the non-tidal part of the importance it has abroad, and they can be made deep enough for canal barges and boats of that type only by artificial means. Weirs have been constructed (on the Severn and other rivers) across the non-tidal portion of streams by means of which the upper reaches have been deepened, thus allowing barge traffic to be carried on. When this is done, it is necessary that these weirs be of sufficient length not to retard the flow in times of flood. Sir William Cubitt adopted the practice on the Severn of placing the weirs obliquely across the channel, and making the weir of a length that the rectangle formed by its length and its depth below the flood line should be equal to the rectangle of the river above the weir within the same flood limits. Fig. 7 shows forms of weirs used in the Severn.



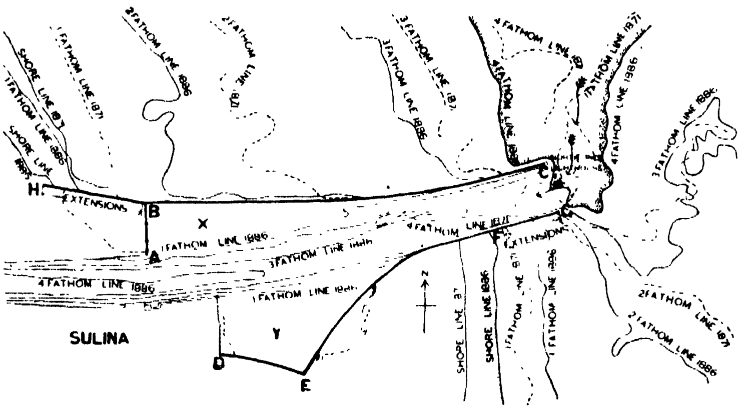
7. WEIRS ON RIVER SEVERN

Tidal Rivers. The term *tide* implies the action of the ocean water in rising and falling, and is due to the force of attraction of the sun and moon on the water of the earth's surface. Tides are divided into spring tides and neap tides, the high-water level of the former being greater than the latter, and the low-water level is generally lower. This difference of level is the vertical rise above mean low-water of spring tides. The *range* of the tide is the vertical difference between high and low water of any tide. The navigable rivers in this country may be regarded simply as being formed and kept open mainly by the action of the tide, and our chief ports are practically dependent on tidal navigation.

The conditions of a river under the influence of the tide are that it has a regular flow and ebb, usually taking place twice a day. The tidal portion of the river is that which is affected by tidal action during the rise of an ordinary spring tide, and not that which is occasionally affected by extra high tides. The tides in estuaries are propagated from the great tide wave of the ocean. The laws of propagation, which are somewhat obscure, were first investigated by Mr. Scott Russell, who showed that the passage of tides through estuaries is quite distinct from the tidal current. The current which flows into the river is due entirely to the slope or fall on the surface of the water. The amount of this slope depends on the rapidity with which the tide rises and the degree of obstruction presented to its propagation up the river. Stevenson summarises the principles for works of improvement of rivers as follows: to deepen the level of the low-water line; to increase the range of the tide; to accelerate the propagation of the tide through the channel of the river; to prolong the duration of the tide in the river; to equalise the velocity of the tidal currents, removing rapids and bores; to add to the beneficial scouring power of the river, and to increase the navigable depth.

The Engineer and Tidal Rivers. In dealing with the tidal part of rivers, the object of the engineer is to facilitate the propagation of the tidal wave, the result of which is to increase the tidal influence, and to prevent the heaping up of the waters in the lower reaches during flood tides. This heaping up of the water in the lower reaches is due to the circuitous course of the river, the projection of obstacles from the banks, and various other causes. The result is to check the propagation of the tide-wave, and, where the tide rises rapidly, to heap up the water at the mouth and cause a bore, due to the early waves of flood tide being retarded so much that they are overtaken by the succeeding ones, or, in other words, the water is heaped up until a slope is formed, causing the succeeding waves to ascend the river in the form of a breaking wave.

The deepening of the bed, and consequent lowering of the low-water line, allows the tide to extend further up the river. If the non-tidal section be made sufficiently large to carry off the occasional floods, the velocity in ordinary times will not be sufficient to prevent detritus depositing, and the bed filling up again, unless the section thus obtained is affected by tidal action. In flood times, the upland water will displace a certain amount of the tidal water for the time being, thus remaining in the river bed instead of flooding the surrounding country.



8. TRAINING OF THE DANUBE

The removal of all obstacles to the flow of the tide is the object to which attention has chiefly to be directed in designing improvements in the department of navigation. In order to form a satisfactory opinion it is necessary to have an accurate survey, showing the depths of the water and the breadths of channel throughout the whole extent of the river, as well as the amount of tidal range, the velocity of the currents, the rise on the bed, and the nature of the materials of which the bottom and banks are composed.

It may be laid down as a general principle in designing works for river improvement, on the one hand, not to adopt a waterway so great as to reduce the scouring power and produce shoaling, or, on the other hand, so small as to increase the current beyond that convenient for the proper management of vessels.

Effect of Improving Tidal Rivers. The tide, in improved rivers, begins to flow earlier than it did before, and a larger body of water is carried up the navigable channel, where its effect is most useful, but the same works which increased the propagation have, by removing obstructions, decreased the heaping up of the tide, and, consequently, the velocity of the tide current. Wheeler gives the following conditions as being essential for a tidal river in good order :

1. The tidal wave at the foot of the tide should be propagated at a rate of not less than 10 miles an hour.

2. The level of high-water should not be lower at the port up the river than at the mouth.

3. The duration of the tide—that is, from first flood to high-water—should not be less than from four to five hours.

4. The velocity of the tidal current should not exceed 2½ miles an hour.

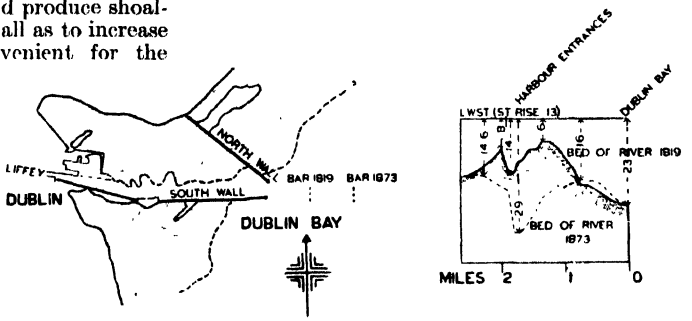
5. The depth at low-water should be sufficient for the navigation of the ordinary craft frequenting the port, and at mean high-water should allow 2 ft. under the keel of the largest vessels.

6. The width should diminish from the mouth upwards, the progressive widths being greater in proportion at the lower end than the upper.

7. The channel should not have in it curves of a radius less than 2,500 ft.

8. The section of the channel should be large enough to allow the upland waters in floods to flow down at a velocity that will not materially interfere with the navigation.

Non-tidal Rivers. In non-tidal rivers, training works have for their object the regulation of the channel, in which the volume of water flowing downwards to the sea varies at different times. In rivers above the range of the tide, or where they flow into tideless seas, training works preserve the channel from the tendency of the suspended matter in the water to deposit, due to the reduced velocity, as is the case where rivers widen out or where they meet the tideless sea. In tidal rivers the conditions differ from the foregoing, inasmuch as the fresh water volume or flow is affected by the tidal flow both in ebb tide and flood tide. Where a river flows through a tidal estuary, the problem to be dealt with is to preserve a navigable channel where there is a tendency to form banks, frequently shifting and varying in their positions, and therefore proving a source of difficulty if not of danger to navigation. Rivers in their natural state usually vary in width, depth, and in direction. The object of training works is to maintain uniformity in the width and depth of the navigable channel. Much consideration is required in settling

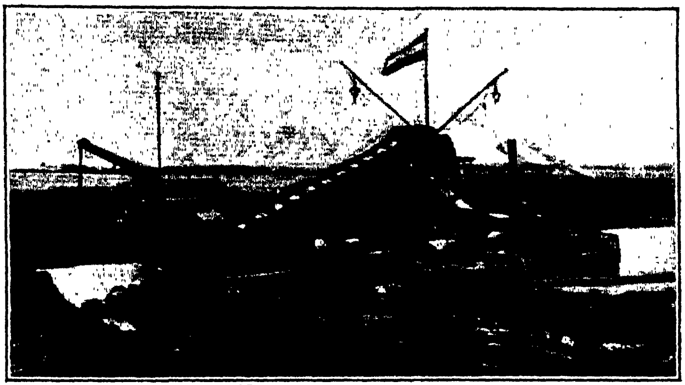


9. TRAINING OF THE LIFFEY

the nature of the works to effect the contemplated improvement of a river channel. For instance, it is possible to improve one part of a river by removing shoals, but at the same time deposits may be occasioned elsewhere. This is often caused by the erosive action of an increased velocity of current (due to the training works) removing material from the bed or sides of a river, and these may deposit beyond the range of the training works.

Estuaries. The entrances to tidal rivers are liable to have bars formed across them owing to the drifting of detritus along the coast, and its deposition, unless the combined land and tidal water at the ebb is able to carry it away seaward. Where this is unable to be done, training walls can be constructed which confine the river in a defined channel, and preserve a velocity and volume sufficient to scour the material seaward into deep water and into currents passing to the sea.

In some cases the material forming shoals and bars, being in a condition too hard for the scour of water to remove, may have to be dredged away in the first instance, after which the natural flow of the river, confined within the artificial training works, would suffice to prevent deposits. The height to which these training walls are carried must depend to some extent on local circumstances. Their main object being to direct the low-water current, it is found that they are generally most effective when carried up to a height equal to half-tide level. The greatest velocity of tidal water is at half-flood and half ebb. The flood tide has a greater erosive action than the ebb. The reason is that, salt water being heavier than fresh, at the beginning of the flood tide the salt water forces its way under the fresh, thus setting up an erosive action disturbing the particles in the river bed, which are removed by the ebb tide. Where the entrance to a tidal river is wide, and has shallow bights, or areas covered and uncovered at flood and ebb, training banks, or reclamation banks, may improve the river by directing the volume of the flood in a more defined channel, whereby the flood water may be carried higher up the river, and the returning ebb water may not be dissipated over these bights, but may be directed in a better channel seawards. In some cases the existence of natural bights, or indents, in the upper parts of a tidal river, and within reach of the tidal range, are valuable, as the water collected therein comes down to the entrance of the river towards the end of the ebb and helps the scour at low ebb. Sometimes artificial reservoirs are made up-stream to collect tidal water at flood tide to accomplish this.

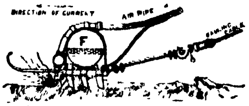


10. BUCKET DREDGER

11. GRAB DREDGER
(Used by Armstrong, Whitworth & Co., Ltd.)

Training a River. An example of the successful training of a river is that of the Sulina mouth of the Danube [8]. These training works, extending a mile from the shore line, were carried out beyond the site occupied by the bar, and thus concentrated the scour of the current right across the bar. The depth of water over the bar was thereby increased from 10 ft. in 1857 to 20 ft. in 1872, and this depth has since been maintained. The walls were of a temporary nature to start with, formed by an outer row of close piling with two inner rows of ordinary piling supporting a platform of timber 4 ft. above the sea level, with stones deposited on each side of the close piling. A solid concrete superstructure 10 ft. wide ultimately replaced the timber structure. The concrete (formed of one part cement to three parts sand and gravel) was deposited in movable wooden frames up to the water level. Above this the concrete was made of one part cement to six parts of sand, gravel and stones. As the work progressed seawards, the foundations were prepared by divers, and then concrete blocks weighing 18 tons were lowered into position and their interstices filled with newly-made concrete. One other illustration will suffice to show how the objects of training works are attained.

Figure 9 shows the improvement in the River Liffey due to training walls. The bar was caused by littoral drift. The wall for about half of its length is 6 ft. above high-water level, thence dropping to high-water level, and then gradually sloping to below low-water level. By the construction of these walls the velocity of the ebb tide was increased from 1¼ miles to 3 miles per hour, and produced an increased depth of 7 ft. over the bar in the first thirty years. The whole wall was not built above high-water level because, if it had been, there would have been a strong current bearing sand during the first half of the ebb tide, and this, meeting the opposing current from the bay, would deposit the sand and form a shoal.



12. SCOURING DREDGER

Dredging. If the current, however, fails to scour away the bar, dredging has to be resorted to. Should the material be very solid, such as rock, blasting is necessary to loosen the materials, which can then be dredged.

There are several methods of dredging, which may be classified as follows:

(1) Bucket dredgers.
(2) Grab dredgers.
(3) Eroding and scouring dredgers.
(4) Pump and suction dredgers.
(5) Rock-breaking dredgers.

The illustration [10], reproduced from "Engineering," shows a bucket dredger.

An hydraulic grab dredger is shown in **11**. This type of dredger is very useful for removing gravel or similar material.

Eroding and Scouring Dredgers. Harrows of different descriptions, and also specially designed ploughs, have been employed with success. They are towed over the bed of the river and break up the soft material, which is then scoured away by the current. Air and water, forced into the silt or fine sand, has a similar effect. Figure **12** shows a method of scouring produced by compressed air. The float, F, serves the purpose of preventing the plough from sinking too far into the mud.

Pump and Rock-breaking Dredgers. The use of pumps for dredging has been successfully employed in various localities. The presence of stones, etc., causes a great deal of damage to the pumps, consequently restricting their use to places where only mud, or very fine sand, is to be found. The ball pump was invented to prevent this damage. The material, which is received at the centre, is brought by a spiral duct into the shell of the pump. This duct transforms the motion of the material into a rotary one in the same direction as the blades of the inner fan. The material on passing through the fan leaves the blades tangentially. This form of pump is distinct from the ordinary centrifugal pump.

When rocks have to be removed, and where it is inadvisable to employ explosives, heavy rams, with chisel points, are used. These rams pulverise the rock, which is then removed by bucket or grab dredgers.

Excavating Large Canals. In a paper on the Panama Canal, read by M. Philippe Bunan-Varilla, before the London Society of Arts, in January, 1907, some interesting figures were given of the uses to which dredgers can be employed for the excavation of large quantities of material. Until quite recently, when it became necessary to excavate vast quantities of material for canal purposes, the steam navvy has been employed for discharging the excavated material into trucks running on rails. When it becomes necessary, as for the purpose of a canal like the Panama Canal, where the country is frequently visited with heavy falls of rain and the attendant disorganisation of the system of road carriage and excavation on land, owing to the washing away of the lines, etc., it becomes an important problem whether this cannot be done better by water-borne dredgers resulting in a great saving of expense.

In the paper referred to, part is devoted to this problem, and it is suggested to carry out the construction of the work on the lines indicated above. The material, after being dredged, is emptied into barges and is transported by them into deep water, when by opening traps in the bottoms of the barges the material is got rid of. It was stated that a barge was capable of carrying 1,000 cubic yd., and that the dredgers were able to excavate 14,000 cubic yd. per day under the most unfavourable conditions. In the excavation for the Manchester Ship Canal by the Lobnitz process of rock drill, the cost, according to Mr. Hunter, was 9d. per cubic yd. The excavation for the Bitter Lakes of the Suez Canal for the purpose of deepening the Canal was carried out at a cost of 1s. per cubic yd., by means of dredgers, without explosives and without interrupting the traffic.

RATIO AND PROPORTION

Rectangles in Connection with Circles. Simple Theorems from Four Proportionals. Proportional Division of the Sides of a Triangle

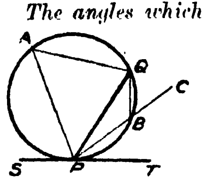
Group 21
MATHEMATICS
37
GEOMETRY

continued from page 5198

By HERBERT J. ALLPORT, M.A.

Proposition 50. Theorem

The angles which any chord of a circle makes with the tangent at its extremity are equal to the angles in the segments into which the chord divides the circle.



Let PQ be a chord of the ⊙ PAQB, and SPT the tangent at P.

It is required to prove that

$\angle QPT = \angle PAQ$, in the segment PAQ,

and $\angle QPS = \angle PBQ$, in the segment PBQ.

Proof. Produce PB to C. Then PAQB is a quadrilateral in a ⊙.

$\therefore$ $\angle$s PAQ, PBQ are supplementary (*Prop.* 41).

But $\angle$s PBQ, QBC are supplementary.

$\therefore$ $\angle QBC = \angle PAQ$.

Now, let the point B move up to P. PC will then coincide with PT, and the $\angle QBC$ with the $\angle QPT$.

$\therefore$ $\angle QPT = \angle PAQ$.

Again, $\angle$s QPS, QPT are supplementary, and the $\angle$s PAQ, PBQ are supplementary. And it has been shown that $\angle QPT = \angle PAQ$.

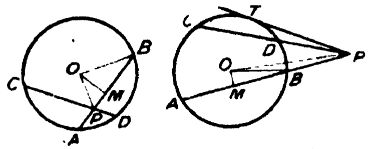
$\therefore$ $\angle QPS = \angle PBQ$.

Definition. If a point P is taken in a straight line AB, the point is said to divide AB into two *segments* AP and PB. If the point P lies between A and B the line is divided *internally*; if P lies in AB produced, the line is divided *externally*.

Proposition 51. Theorem

If two straight lines drawn through any point P cut a circle in A, B and C, D respectively, then the rectangle AP . PB is equal to the rectangle OP . PD.

Let ABD be a ⊙ whose centre is O. Through the point P draw any two straight lines cutting the ⊙ at A, B, C, D.



It is required to prove that rectangle AP . PB = rectangle CP . PD.

Proof. Draw OM $\perp$ to AB. Join OP, OB. Then OM bisects AB (*Prop.* 36).

Now, when P lies within the ⊙,

$$\begin{aligned}\text{Rectangle } AP\,.\,PB &= (AM - PM)(PM + MB)\\ &= (BM - PM)(BM + PM)\\ &= BM^2 - PM^2\\ &= (BM^2 + OM^2) - (PM^2 + OM^2)\\ &= OB^2 - OP^2\\ &= \text{square on radius} - OP^2.\end{aligned}$$

In the same way it can be proved that

Rectangle CP . PD = square on radius − OP^2.

$\therefore$ rectangle AP . PB = rectangle CP . PD.

Similarly, when P is outside the ⊙, we get

Rectangle AP . PB = OP^2 − square on radius
= rectangle CP . PD.

Corollary. In the case when P is outside the ⊙, suppose CDP revolves about P; the points C, D then approach one another until they coincide, and CDP becomes a tangent to the ⊙. The rectangle CP . PD becomes the square on the tangent from P. Hence we have:

If the tangent to a circle at any point T meets a chord AB in P, then $PT^2 = PA\,.\,PB$.

Note. By a method similar to that of *Prop.* 42 we can prove the converse of *Prop.* 51—*viz., If when two straight lines AB, CD intersect in P, the rectangle AP . PB = the rectangle CP . PD, and the four points A, B and C, D are both on the same or both on opposite sides of P, then A, B, C, D are concyclic.*

Again, the converse of the above corollary is true—*viz., If from a point P in the chord AB a straight line PT can be drawn to the circle so that $PT^2 = PA\,.\,PB$, then PT touches the ⊙ at T*

For, suppose the ⊙ cuts the straight line PT again at T′. Then PT . PT′ = PA . PB (*Prop.* 51) = PT^2 (*Hyp.*).

$\therefore$ PT = PT′, so that T and T′ coincide.

$\therefore$ PT is a tangent.

RATIO AND PROPORTION

Ratio. Two quantities *of the same kind* can be expressed in terms of a common unit. Suppose the first quantity contains this unit *a* times, and the second contains it *b* times, then the ratiio of the first quantity to the second is the fraction $\frac{a}{b}$.

The ratio is generally denoted by $a : b$.

a is called the *antecedent* and *b* the *consequent* of the ratio.

Proportion. Four quantities are in proportion when the ratio of the first to the second is equal to the ratio of the third to the fourth.

Thus, if *a* is a *length* of 1 ft. 9 in., *b* is a *length* of 2 ft. 4 in., *c* is an *area* of 6 sq. ft., and *d* is an *area* of 8 sq. ft., then the ratio $a : b$ is the fraction $\frac{21}{28}$, or $\frac{3}{4}$; the ratio $c : d$ is the fraction $\frac{6}{8}$, or $\frac{3}{4}$. Therefore, since these ratios are equal, the four quantities *a*, *b*, *c*, *d* are in proportion. The proportion is denoted by $a : b :: c : d$.

a and *d* are called the *extremes*; *b* and *c* are called the *means*.

d is called a *fourth proportional* to the three quantities *a*, *b*, *c*.

Three quantities are said to be proportionals when the ratio of the first to the second is equal to the ratio of the second to the third. Thus, a, b, c are proportionals if $a : b :: b : c$.

c is called a *third proportional* to a and b.

b is called a *mean proportional* between a and c.

Continued Proportion. If any number of quantities be such that the ratio of the first to the second, the ratio of the second to the third, the ratio of the third to the fourth, and so on, are equal to each other, the quantities are said to be in continued proportion.

Thus, quantities in continued proportion are also in *geometric progression*. [See page 3914.]

Four Proportionals. When a, b, c, d are in proportion, we know that $ad = bc$. [See page 3695.]

The following results are also easily obtained:

(1) $b : a \quad d : c$
(2) $a : c \quad b : d$
(3) $a+b : b \quad c+d : d$
(4) $a-b : b \quad c-d : d$
(5) $a+b : a-b :: c+d : c-d$.

For example, since $a : b :: c : d$, we have

$$\frac{a}{b} = \frac{c}{d}.$$

Therefore,

$$\frac{b}{a} = \frac{d}{c},$$

i.e., $b : a :: d : c$.

Again, we know

$$\frac{a}{b} + 1 = \frac{c}{d} + 1,$$

so that

$$\frac{a+b}{b} = \frac{c+d}{d},$$

which gives us (3). In a similar way we obtain (4). By dividing the result (3) by (4) we obtain (5).

Division of a Line in a Given Ratio. A straight line AB is said to be divided *internally* at C in the ratio $a : b$, when AB can be divided into $a + b$ equal parts, of which AC contains a, and CB contains b.

Again, if $a > b$, and AB is divided into $a - b$ equal parts, we can produce AB to C so that BC contains b of these parts. We then have AC : BC :: $a : b$, and AB is said to be divided *externally* at C in the ratio $a : b$. Similarly, if $a < b$ and AB is divided into $b - a$ equal parts, we can produce BA to C so that AC contains a parts. We then have AC : BC :: $a : b$, and BA is divided externally at C in the ratio $a : b$.

Proposition 52. Theorem

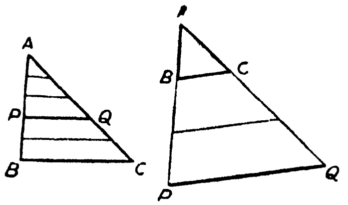
If a straight line is drawn parallel to one side of a triangle it cuts the other sides proportionally.

In the Δ ABC let the straight line PQ be drawn || to BC, cutting AB in P and AC in Q.

It is required to prove that

AP : PB :: AQ : QC.

Proof. Suppose that AP : PB :: $a : b$. Then, if AP is divided into a equal parts, PB can be divided into b of such equal parts. Through all the points of division draw straight lines || to BC.



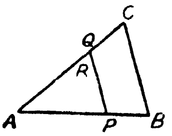
Then, AQ will be divided into a equal parts, and QC will be divided into b of such equal parts; that is,

AQ : QC :: $a : b$.

∴ AP : PB :: AQ : QC.

Proposition 53. Theorem

If a straight line cuts two sides of a triangle proportionally, it is parallel to the third side.



Let a straight line cut the sides AB, AC of the Δ ABC in P and Q so that

AP : PB :: AQ : QC.

It is required to prove that PQ is || to BC.

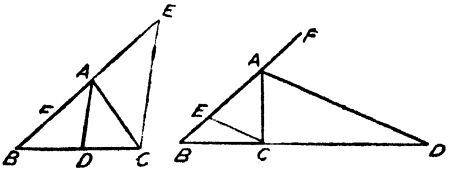
Proof. Draw PR || to BC, cutting AC in R.

Then AP : PB :: AR : RC (*Prop.* 52).
But AP : PB :: AQ : QC (*Hyp.*).
∴ AR : RC :: AQ : QC.
∴ AR + RC : AR :: AQ + QC : AQ;
AR : AC : AQ.
∴ AR = AQ.
∴ Q and R coincide, and PQ is || to BC.

Corollary. If AB : AP :: AC : AQ, then PQ is || BC.

Proposition 54. Theorem

If an angle of a triangle is bisected, internally or externally, by a straight line which cuts the opposite side, or that side produced, the ratio of the segments of that side is eq
the other sides of the triangle.



Let the ∠BAC of the ΔABC be bisected by AD, internally in the first figure, and externally in the second—*i.e.*, in the second case let AD bisect the exterior ∠FAC.

It is required to prove that

BD : DC :: BA : AC.

Proof. Through C draw CE || to DA, cutting BA produced, or BA, in E.

Then, since DA is || to CE, and CA meets them,

∴ ∠DAC = ∠ACE;

and, since AE meets the ||s,

∴ ∠DAF = ∠CEA.

But ∠DAC = ∠DAF (*Hyp.*).

∴ ∠ACE = ∠CEA.

∴ AE = AC.

Also, since AD is || to one side of the Δ BCE

∴ BD : DC :: BA : AE.

∴ BD : DC :: BA : AC.

THE MAKING OF SADDLES

The Saddler's Masterpiece. The Riding Saddle. Details of the Making of Cart and Van Saddles. Various Accessories. Application of Machinery

continued from page 5192

By W. S. MURPHY

WE have reached the stage where the materials and manufacture of all kinds of saddles may be considered. Figures **14** to **18** illustrate many of the operations in making saddles, the photographs having been taken in the works of Messrs. Middlemore & Lamplugh, Birmingham. The ironmongery required comprises saddletrees, stirrups, terrets, buckles, nails, and other smallware.

Cutting Out. The sizes and forms of saddles vary a good deal, and we cut them to pattern, grading to size. The main parts of each kind of saddle are as follow:

Riding Saddles. Seat, skirts, flaps, panels, stirrup leathers, gullet piece, welts, and trimmings. Textile parts: Webbing and linings of various kinds.

Cart Saddles. Panels, panel covers, flaps, housings, girths.

Van Saddles. Flaps, panels, top covers, girths, straps.

The Saddler's Masterpiece. Everyone knows that the riding saddle is the finest product of the craft. To make a saddle that will be comfortable for both horse and rider and at the same time look well and wear well is no mean achievement. Fashion has a good deal to say in regard to the shape and appearance of saddles, and we therefore have a number of shapes. Some riders like a fore part, or gullet, low, and others want it high and slanting well towards the seat; some wish the seat broad and flat at the back, and others must have the cantle high and pointed. We have to adopt several styles and classes of covering, too. This does not refer to imitation instead of real hogskin, and other cheap devices. In all those we refer to, the seat is of hogskin; but some may be made with flaps and skirts of plain leather, others with skirts of hogskin and flaps of plain leather; kneecaps may be wanted or disliked; and it is seldom nowadays that an ordinary saddler is requested to make a saddle that is all hogskin from seat to kneecap. Most common is the saddle with the hogskin seat, plain leather skirts and flaps, without kneecaps, and this we shall build up bit by bit

14. RIDING SADDLE MAKING

Saddletree. Consisting of pommel, or gullet, cantle, or back, saddle bars, and stirrup bars, the saddletree forms the frame of the saddle. In choosing it, regard must be paid to the size and breadth of the horse; a saddletree too narrow for the horse will produce discomfort and injury, with consequent trouble for the saddler.

Foundation. Having stretched three lengths of good webbing, take the first piece and nail it in two lengths from saddle bar to cantle to form a triangular belt; stretch the second piece across and nail it down, leaving a large piece hanging free; the third bit, which may be of inferior quality, is nailed close to the first webbing, and joined by sewing. Cover all over with two pieces of linen and tack down tightly. Make two pads of basil leather stuffed with flock, and nail to the edge of the tree, from the cantle forward. With white serge cover the seat all over, nailing and stitching down to the shape of the seat. Make a hole in the serge covering at the centre; secure it from unravelling by waxing the sides of the cut; then stuff with flock, stuffing through the hole till all is firm and even; next close up the hole.

Seat and Skirts. Damp the fine bit of hogskin cut for the seat, and nail it on the saddletree, in such a way that the nail marks will not be visible. Shape it, and pull back over the cantle, reducing the wrinkles to two one on each side. Leave the seat to dry.

Trim the skirt leathers. Sew on to the under sides pieces of lined leather to connect the skirts with the saddletree. Cover over both skirts with hogskin, stitching down with fine yellow silk. The seat is dry by this time. Shave it all round with a slight skive. Put skirts and seat together, and mark for sewing. Stitch a welt on each of the skirts; then sew skirts, welts, and seat together. Preparatory to adjusting the seat, the projecting points of the tree before the saddle bars must be covered with thin hogskin or basil. Make the seat damp, adjust it and the flaps on the saddletree, and nail down at the front; nail down the side pieces we joined to the skirts, and see that the saddle is kept straight. Pull the leather and the web straps forming the foundation over together, and nail them on to the saddletree.

Flaps. Line the flaps with serge and form the pads. Lay the flap on its place under the skirt on the saddletree, mark the points to be cut, and make the nicks required. Fasten each flap in position, so that the pads may come loose under the corners of the skirts. Run a few stitches through the web and side piece; drive a nail through the fore part into the saddletree, and another in the tree at the back; slant both nails and clinch them.

15. MAKING HARNESS SADDLES

Pommel. The gullet, like Mrs. Hubbard's cupboard, is bare, and to cover it we form a gullet-piece out of a plain bit of leather the length of the pommel and an inch wide, and a bit of hogskin slightly wider. Make these into a binding by joining them together over a cord and fasten the binding over the pommel. Join to the points of the flaps by driving silver staples, one leg through the gullet-piece and the other through the flap point, right to the neck in the saddletree. Conceal the joint of the gullet-piece, or pommel cover, with the flaps by pasting neatly over each join a piece of hogskin, skived away at the sides to make an apparently flat surface.

Girth Straps. Cut six straps 13 in. by 1 in. and crease in the usual way. Fold back the web and leather we left hanging, and sew two straps on each side, nailing the other two, one on each side, to the saddletree. Make two peaked flaps, called underskirts, and nail one on each side under the girth straps.

To finish off the body of the saddle we must put in a little bit of leather here and drive a nail through there, in ways which are obvious in practice, but rather too minute to describe.

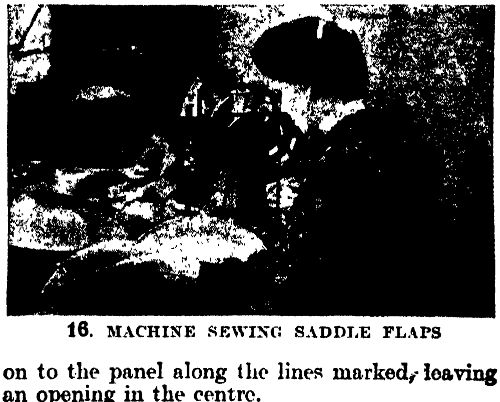
Panels. Mark carefully the lines of the panel on both sides, and trim to size. Paste on the top lining, and let dry. Lay on the underlining of serge, large enough to allow for stuffing, and tack it on; sew right round and stuff. Quilt the lining. Mark lines across the panel flaps, and quilt over. On the fore ends of the panel two pockets are made for the points of the tree. When setting, push the points well into the pockets; tack the panel close around the front of the pommel; drive two tacks in between the points of the crupper loop at the end of the saddle. In addition, put three nails through on each side; one about 8 in. from the cantle end, one about the middle and one at the front.

Stirrup Leathers. Saddles without stirrups are incomplete. No new or special method is involved in the making of these; they are simply heavy straps designed to hold the stirrup irons. Unlike most straps, the stirrup leathers are worn flesh side outwards, and this has to be remembered when creasing and bending the buckle chape. The buckle is simply sewn into the thick end of the strap, and the holes are punched. Thread the strap through the stirrup iron, and hang on the stirrup bars on the saddletree. On the last, inventors have exercised their ingenuity to find a strong iron which would allow the stirrups to go when the rider happened to fall off. Many a rider who has lost his seat would have come off scatheless but for the drag of the stirrup in which his foot has become entangled.

Cart Saddletree. Various forms of cart saddletree have been made, but in main lines there is very little difference between them. You have always the curved double back with the two boards fixed flat under it. On this skeleton we have to build our saddle.

Panel. Cut the panel ½ in. longer than the boards, and 2 in. wider than the central width. Make both sides alike, and whip together, cutting an inward slant on the fore part. Smooth down the stitches, and lay under the saddletree; mark where the centre of each board touches the panel; on the marks sew a tag of leather for nailing on to the boards at the proper time.

Lining. Cut and shape a lining of strong woollen check cloth to both undersides of the panel; stitch on to the lining the leather basil facing for the panel; sew both on to the panel. Slit the lining in the centre of the panel. Draw a line on both sides, beginning about 1½ in. from the centre join of the panel and running out to 2 in. wide at the front. Tack the lining underneath, keeping the slit in the centre. Put a bound wisp of straw 9 in. long in the centre across the gullet, and after drawing the basil facing back on the marked lines, stitch the wisp firmly from above. Stitch the lining on to the panel along the lines marked, leaving an opening in the centre.



16. MACHINE SEWING SADDLE FLAPS

Stuffing. Lay the panel on the bench, with the lining uppermost, and nail the corners. Now stuff the straw regularly in through the slit on the lining. When fairly tight, level down, and make a space evenly between the lining and the stuffing. Into this thrust a layer of flock, and level down the whole pad. Do the same on the other side and so make the panel complete.

Crupper Dock. To join the crupper to the saddle, we must have some kind of link. A simple, though not very satisfactory, device is the nailing of a strong belt on the centre of the saddletree. This necessitates a buckle on the crupper, while the dock needs only the crupper put round it. Make the dock four plies of leather, sewn into one over two tinned rings, two plies, of course, going on each side of the rings. Bend the dock so as to point the ends on to the saddletree boards. Into the boards drive two staples, one on each ring, and clink the dock to the saddle.

Flaps. Cut the flaps 9 in. deep and 1 in. longer than the boards. Measure on the saddletree for the openings to let through the two girth straps; cut out the openings; edge all the sides and edges of the flaps, and race three lines round the sides. Make the fore girth 4 ft. 10 in. long, and the back girth 5 ft. 2 in.; edge, race, crease, black, and polish; turn down the chapes; stitch in the buckles, and form the loops, adding two running loops. Set the flap now in position, and tack each end on the board; run the girths into the openings left for them; nail flaps and girths down on to the boards.

We are slowly building up our cart saddle. The flaps, girths, and dock are in position, and now comes the turn of the panel, with its needful pads. Having placed the panel, nail the tabs which were sewn on the panel sides, front and back, firmly on to the boards.

Housings. Simple as the housings appear, mere covers for the top sides of the saddletree, the man who is careless with them always comes to grief. Cut both to lie the full length over across the saddletree, and between 5 in. to 7 in. broad. The back housing should be bulged out to the middle in shape, while the front one may be curved inwards on the outer edge and must be straight to lie close to the ridge in the middle at the inner side. Nail both down on the saddletree in the centre; then pull out to the sides, and tack down so that the surfaces will be smooth and firm. Drive in nails all round, about 2 in. apart, keeping the edges flush with the edges of the saddletree. Stitch down at the four corners on the flaps; ornament with either brass beading or fine leather held on by fancy nails.

17. FINISHING RIDING SADDLES

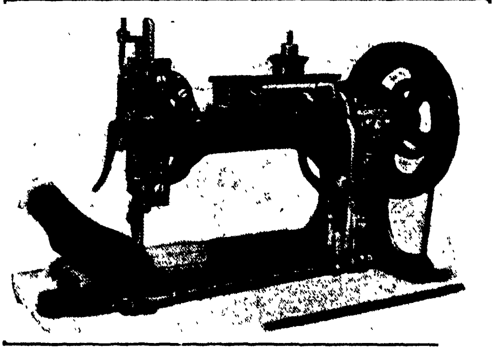
Van Saddles. Though the saddletree of the van saddle is almost a miniature copy of the cart saddletree, the making of the saddles must be learned separately. No man, after having been taught to make a cart saddle only, could undertake a van saddle. If he did, he would either show marvellous cleverness, if successful, or come to grief.

18. STUFFING PADS FOR CARRIAGE HARNESS

Saddletree. As a rule, saddletrees have to be trimmed a little; carefully shave to size. Fix the places for the bearing-rein, stand hook, and terrets, and bring the sockets down flush with the surface of the tree. For a covering of the saddletree, cut the pieces of thin leather selected for the purpose when gathering and cutting out the stuff; shape them to the sides of the tree, an inch overlapping all round. Lay on the saddletree, and into each make cuts the depth of the projecting boards, so that they will fold under the centre piece. Damp them; tack each end of the side pieces close to the board, and stretch very tightly over the whole surface; fasten with tacks here and there; pull the centre part well under the tree, and fix firmly with nails.

Flaps. The flaps should be made to fit the tree a few inches above the end of the centre groove, and the length may be about 15 in. Shape the pieces of patent or plain leather to the patterns, and note that they are right and left. This is important, for the fore side is rounded wider than the back. Race the lines for stitching on the lining; stitch a double row round. Clear the edges with the edge tool, and polish; then join with a stitch at the top. Cover the joint front and back with a strip of leather, stitched on both sides and at the front. Put the tree exactly in position on the flaps, and mark for further operations. Indicate the width of the boards and the breadth of the saddletree on both sides. Lift off the tree, and slit the leather according to the lines. Now we are ready to fasten flaps and saddletree together. Make the centre slit meet the centre of the tree; nail the flaps along the sides of the tree, as close as possible; carefully adjust over the boards, and nail down.

Top Cover. Cut the top cover out of a piece of strong leather. Make it the same size as the tree in width, and leave 2½ in. from the bottom, to allow space for the back band. Crease across both ends, and bevel with the heated bevel iron. Sew two rows across the points. But we must not smother the socket of the standhooks and terrets we put in not long ago. Place the top cover in position on the tree, and lightly tap it down with the mallet, thus imprinting the holes on the leather. Cut out the holes; then nail the cover on the tree, driving a strong nail into each corner. Run the beading along both sides of the top and through under the boards of the tree; tack on to the underside of the boards.



19. WAXED-THREAD SEWING MACHINE

Panels. Shape the body of the panel to about the same size as the flaps. Cut out of the same leather as the flaps a facing 1½ in. wide; tack it round the sides of the panel. Measure and cut the serge lining, and whip it to the inner side of the facing and to the bottom of the panel. Stuff the lining with carded flock, keeping it smooth and even. To make the sides of the panel stand out flat, fill up the inside of the facing with a thick cord or stiff wisp of straw right along. Rule lines 1½ in. apart on the panel, and stitch along the lines, making a quilting. Place the panel of the tree, and tack it in position. Having prepared some wires 5 in. long, pierce holes with a bent awl in the flap; pierce holes corresponding in the panel; draw the wire tightly through the holes, pulling flap and panel together; with the pincers twist the two ends of the wire; cut off the long ends, and thrust the knot into the hollow of the facing. Repeat this till the panel is fully secured. This work is also done by machine [19].

20. MAKING TRAVELLING BAGS

Make the straps and girths in the way before directed, and sew on to the bottoms of the flaps, the girth on the off-side, and the strap on the near side.

Saddles for gig, four-wheeler, and hansom, are built on the same principles, though the gig and four-wheeler saddles are simpler, and that for the hansom is lighter.

Accessories. Of the group of articles which we may designate *accessories* there is not much to be said.

Breastplate. Used for preventing the saddle from slipping back on the haunches, the breastplate consists of long side straps, bound over at the top by the neck strap, two short straps to be looped to the saddle, and a girth strap extending from the V-joint of the side straps between the horse's fore legs to the girth.

Martingale. This is a simpler breastplate, the body generally being made round, lying on the horse's neck like a hoop.

Saddle Girths. Girths are broad bands buckled round the belly of the horse to keep the saddle in position. They may be made of wool, mixed wool and cotton, leather lacing, and other materials, with leather ends and good buckles.

Saddle-cloths. Generally made of fine felt, the saddle-cloths are shaped to form a wide margin round the saddle, and bound with tape. They are meant to protect the back of the horse, and absorb sweat.

Head Collars. Various shapes of head collar are made; but none of them present any difficulty. The main principle of all forms is to combine headband, noseband, cheeks, throatlash, and chin-straps, in such a way as to make them easy to fit and put off and on, while keeping secure on the head of a restive horse.

Tugs. On the tugs the weight and strain of shafts and traces impose a heavy burden. Most important and representative is the shaft tug for van or cab. Cut a strip of strong leather about 2 in. broad, shave and edge it, then overlap 4½ in.; knock together, and make a hole through both leathers. Insert the buckle and brass loop, and stitch firmly the overlap. Pack tightly with hard sole leather, always keeping to shape. Put four rows of stitching through the whole body, leaving a space for the loop to be set in. Make the loop, and stitch in. Finish in the usual way.

Miscellaneous. There are a good many articles which the saddler and harness-maker must learn to make from mere practical experience. Knee-caps, fetlock boots, false collars, and horse clothing involve little that is new.

Machinery. We have touched but lightly on this side of the trade because the machine must always be merely the auxiliary of the craftsman in our work. The sewing machine is the chief mechanical operator with us, and it certainly saves a great deal of labour. Saddlers also make other items, such as bags, purses, portmanteaus [20], letter cases, kit bags.

SPORTING GOODS DEALERS

It is certain that the trade in articles requisite for the pursuit of sports is increasing. The object of this article is to show how a trade in such requisites may be done and the way to do it. Other articles in this section have dealt with Fishing-tackle Dealers [page 2524], and Gun and Ammunition Dealers [page 3149], so that it is unnecessary to refer to these here.

Idiosyncrasies of the Trade. It must not be imagined that the selling of goods required for English sports and games is a simple matter; it is far from that. As a matter of fact, it is not generally carried on alone. More often than not it is an auxiliary to the business of a hair-dresser, a saddler, a tobacconist, or an ironmonger. For it must not be forgotten that there is a dead season in outdoor sport, and it is therefore almost imperative for anyone undertaking the business in sporting goods alone to endeavour to work up a trade in indoor games of all kinds as well. Moreover, there are in all the big towns and cities the departmental stores, with their sports departments, to compete against. Then, again, the professional cricketer, or the professional golfer, who manufactures his own bats, or his own golf clubs, is a formidable rival. It is absolutely necessary that the man who desires to make a success of the business must know not only one game thoroughly, but every other game well. He must know not only how to play football, tennis, cricket, croquet, hockey, etc., but he should be conversant with the laws of all the games. If he is an expert at cricket or golf, so much the better, but at least he should be a safe man to consult regarding regulations, and naturally he would make it his business to know all that is going on in the world of sport covered by his trade.

The Practical Training. Even with all the attributes mentioned, actual experience in the commerce of the goods is necessary. This is not learnt in the playing fields, or in the actual workshops where the goods are made. It is seldom that a man from the factory starts in business on his own account. Sometimes a professional footballer, cricketer, or golfer may give up the field for the road and get a position as traveller for a large wholesaler or manufacturer of sporting goods. Such a man may obtain sufficient insight into the intricacies of the business to justify him in starting on his own account. The best experience is to be obtained by going as a youth into a big wholesale and manufacturing business which does a miscellaneous trade in goods for outdoor and indoor games, and "working up." There is no recognised apprenticeship system in the trade, and the youth who goes as errand boy has the same opportunity, provided he has equal intelligence, as the youth whose father can pay a premium for his experience. Failing the possibility of such a training, the business may be efficiently absorbed by the alert youth in the sports department of a large stores.

Utilising the Training. The buyer of sporting goods for the department of a large stores is a position worth trying for. In some of these departments they specialise in tennis, hockey, cricket, and so on; and if the buyer knows all there is to be known about footballs, for instance, he may make a reputation for his house as the house for footballs. But many young men prefer a more independent line, and hanker after businesses of their own. So one with a genuine love of sports, a good all-round experience, and a fair share of business acumen, who has a capital of at least £200, would look around, in the country towns more particularly, for a desirable opening. There are few country towns or even villages nowadays that have not one, or several, cricket, football, or golf clubs. Ladies' schools and seminaries abound, as well as boys' schools and training colleges, and these provide prospective customers. Hockey, tennis, lacrosse, and even cricket are as much a necessary part of the modern girl's school education as modern languages.

The Shop. In the matter of decoration and display, the establishment of the dealer in sporting goods need not be elaborate. This means that the size of the shop and the choice of the fittings are secondary considerations. The main things are the locality, the soundness of the stock, and, above all, the knowledge of the shopkeeper. A small shop, therefore (costing probably in a small country town not more than £30 to £40 a year rent, with living rooms attached), would be simply fitted with a few shelves and racks, a counter, lighting supply, and perhaps a glass wall case, the whole fixtures not costing more than £30 all told. A knowledge of manufacturing and mending is, of course, extremely useful, but this department is not actually necessary for a beginner, who can get all he requires done in that way by the regular recognised factories.

The First Stock. The choice of an opening stock must be determined by the needs of the neighbourhood, primarily, but it must also be general. In any case, it need not necessarily be large, but it ought to be varied. In the following table an attempt is made to give an approximate idea of the articles required, the quantities, the cost, and the selling prices. The prices given must, however, be distinctly taken as relative, and the man's experience will enable him to gauge the potentialities of the neighbourhood, so that the list given on the following page may be varied without increasing the outlay—about £70.

As will be noticed, the list deals only with the better-known and more popular outdoor games, and the selection may be regarded as representative of what an opening stock ought to include. It may be possible to buy cheaper and to sell dearer than the prices given, but these may be looked upon as fair average all round.

Peculiarities of the Stock. There are certain articles with which care must be taken in storage. A temperature below 32° F. will ruin good tennis balls, and billiard cues—of which more hereafter—will warp if not kept free from damp or if exposed to excessive heat. Tennis is very popular, and badminton is increasing in public favour annually. There are special manufacturers of known repute

			Retail price
1 doz.	Tennis racquets .		7s. 6d. to 27s each
1 pair	Tennis poles .. .		£3 per pair
4 doz.	Tennis balls .. .		6d. to 1s. each
¼ doz.	Tennis nets .. .		6s., 10s. 6d., and 14s. each
½ doz.	Croquet sets		£8 per ½ doz. sets
1 doz.	Croquet mallets .		£4 per dozen

4 sets	Cricket stumps.	9	10s. 6d., 2s. 6d., 1s. 6d., 1s. each
2 doz.	Footballs .	10	3s. 6d. to 10s. 6d. each
2 doz.	Hockey sticks	0	4s. 6d. to 10s. 6d. each
2 doz.	Hockey balls .	0	1s. to 5s. each

in each branch of the trade, so that the man who knows his business will be able to choose the proper make of tennis racquet, football, badminton bat and so forth, and be able to expatiate on the points of the article he is selling. Complete sets for badminton comprising bats, net with portable poles, shuttlecocks, etc., may be had to retail at from 15s. to 45s. per set. They show a profit of fully 25 per cent. Croquet is again coming much into fashion, and hockey is something of a rage at the moment with both men and women. Golf is usually a lean trade for the general dealer in sporting goods. The professionals at the club-houses do it all, seeing that more often than not each pro. has his own make of club which he recommends to learners and to players alike. As for golf balls, their name is legion. The rubber-cored ball in its many varieties is generally regarded as the favourite, and a judicious selection is necessary, as a large stock is costly. Bowls is a difficult business to foster, but it is very popular in some parts of the country, particularly in Scotland. If there is any bowling club in the vicinity it might be diplomatic for the shopkeeper to join it, if possible, and to lay in a stock of two or three pairs of bowls for show purposes. But it is important that he should see that each bowl bears the official stamp of either the Scottish or the English Bowling Association. Cricket appeals mainly to the younger portion of the community, therefore the stock of bats should include an assortment varying in size and quality, so that all ages, from the schoolboy to the full-grown Oxford graduate, may be suited. It is not advisable to stock stumps largely; they usually last a long time and do not get lost like balls, or broken like bats. One or two junior sets should not be overlooked in ordering. It might be advisable to stock a few pairs of wicket-keeping gloves, leg-guards and batting-gloves, provided the neighbourhood is a cricketing resort, but it should be borne in mind that these goods are particularly liable to become shop-soiled. In footballs the No. 5 Association pattern is most generally sold.

Indoor Games. There are many indoor sports to be catered for, and as it is assumed that our young enthusiast is eager to make his field of action as comprehensive as possible, he might lay in a few billiard cues and billiard balls. Half a dozen cues, retailing at anything from 2s. 6d. upwards, would suffice, and two or three sets of balls. Then he might have half a dozen sets of chessmen of different patterns and qualities to retail at from 2s. 6d. to 12s.: the ten-guinea ivory sets would not be advisable at first. He might likewise provide a few sets of dominoes, draughts and draught-boards, backgammon sets, dice and dice-cups, playing cards, card counters, ping-pong sets, "Ascot" sets; and there are innumerable varieties of things like table bowls, table croquet, and variants on all kinds of outdoor games he might stock. A judicious outlay of £10 or £15 on the ingenious and amusing indoor games that are invented every year, and keep winter parties in good humour would well repay the careful buyer and would keep the dead season alive. As a matter of fact, just before Christmas is a favourable time for the beginner to open his shop, provided he can make a good display of inexpensive but alluring parlour games such as "Tiddledy Winks," "Go-bang," "Aunt Sally," "Ludo," "Puff and Dart," and so on. These things get the new man acquainted with the young people, and it is the younger generation which, after all, keeps the outdoor games a-going when the summer comes again.

The "Arts," Athletics and Other Adjuncts. It may be that devotees of the "noble art" reside in the neighbourhood, and a pair or two of boxing-gloves would be attractive. Or the military instinct may be prevalent, and a few fencing foils, fencing masks, gloves and gauntlets, single-sticks and single-stick helmets would not look amiss. Indian clubs are seldom out of place, and the physical culture craze has created a considerable demand for spring-grip dumb-bells, punching balls, exercisers, and developers, and such things as these, small stocks of which might be kept. If schools are a feature of the locality apparatus for calisthenics and musical drill might be requisite, while the time-honoured pastimes of childhood, like glass marbles, humming tops, skipping-ropes, peg-tops, teetotums, whipping-tops, and battledore and shuttlecock should never be lost sight of. An outlay of £5 in such miscellaneous things will make a show that will give delight to the youth of the neighbourhood. There are, of course, many other lines which the dealer may develop as the business grows and should there be a demand. Games like quoits and skittles are popular in some districts, while other neighbourhoods, or the vicinity of a military garrison, may induce the stocking of all the requisites for polo. Archery has a vogue in some parts of the country, but its popularity appears somewhat spasmodic and confined to enthusiasts.

Attracting Trade, and the Reward. The personal element is the strong point, and the young man should endeavour to become associated with as many of the local clubs as possible. Immediately after opening he should issue a trade catalogue, and his catalogue should always be a feature of the local sporting haunts. Large manufacturers of sporting goods, such as John Jaques & Son, Ltd., of Hatton Garden, London, supply excellent and comprehensive catalogues, with the name and address of their customers printed on the covers, for only a nominal sum. With regard to profits, it may be taken as a general rule that the average profit on the turnover comes out at from 25 per cent. to 30 per cent. The outlay is not great, there is little risk of deterioration of stock if ordinary care be taken, and the working expenses at first need not cost more than 5s. or 6s. a week, for a boy to keep things tidy and to run errands.

STATIONERS

The business of a stationer may be called one of the allied trades, because it is usually second in the trio of bookseller, stationer and newsagent. In fact, we find it associated with quite a variety of businesses, and it is a general opinion that anyone can be a stationer. If by stationer is meant handing across the counter a box of pens or a packet of notepaper and envelopes, then to a certain extent this is true. The real stationery business, however, is separate and distinct from all others, and requires a thorough, special training.

Apprenticeship. The term of apprenticeship is five years, and the pay usually begins at 3s. a week with an annual increase of two shillings a week. Of course, this may vary in some houses, but that may be taken as an average. To obtain a thorough training the novice should enter some good wholesale house where he will get a knowledge of all the departments and be initiated into the mysteries of the various sizes and qualities of papers, learn the trade terms, and be taught the difference, say, between a retree and a perfect, a hand-made and a mill finished, and be taught to distinguish between the tub-sized and ordinary engine-sized papers. Here, also, the apprentice acquires a knowledge of the size and bindings of business books which will stand him in good stead afterwards. He would further be trained to a knowledge of the sizes and qualities of envelopes and taught how to parcel and keep stock. If the young stationer intends starting business himself an additional term of service in a retail business would be advisable. When his apprenticeship is finished the young journeyman would begin with a salary of something like £60 a year, which would be increased as experience was gained and adaptability shown.

Stationery. The term *stationery* is a very wide one, and includes anything from the modest notebook to the magnificent Russia-bound ledger which finds a resting-place on the desks of our great banks and commercial houses; or from the school pen and pencil to the beautifully and expensively-mounted fountain pen. In fact, the articles sold by the stationer are so many and varied that in these days of specialising various and separate businesses have been evolved. Thus we have law stationers, scholastic stationers, grocers' stationers, and commercial stationers, together with artists' stationers, etc. As the bulk of the business effected by these firms—"bagmen" they are called—is the result of canvassing, it follows that the choice of a site for shop, office, or warehouse is not of paramount importance; nor need the stock be heavy—business to a large extent being done on commission. To keep any of these businesses going, travellers require to be continually on the road. Prices as a rule are closely cut, and competition is keen.

The General Stationer. The man known as the commercial and general stationer conducts his business on slightly different lines, and is to a large extent dependent on the position and appearance of his business premises. It would be well, therefore, to select a shop in a good business thoroughfare; and the shops of first class stationers are usually found in the best parts of all towns and cities. Generally, it is an old business which has come into the market that is acquired—as new businesses either in this line or that of its intimate associate, bookselling, are by no means numerous.

As the beginner would require to provide for mostly all, or rather more than, the departments enumerated above, a sum of £500 to £600 at least would be required fairly to start him in business. If he is a total stranger to the place it might be well for him to allow himself to be guided to some extent by the representative of some good wholesale house who has a knowledge of the requirements of the district. Of course, we say "to some extent," as while it is well to cultivate mutual trust and good relations between buyer and seller, it is a mistake to be too confiding. It may, however, be taken for granted that the representatives of first-class houses—and we are speaking only of such—do not like to see the parcel they sold still resting on the shelves when calling for repeat orders. It would be well also to continue the services of former assistants, who would not only advise as to the wants of the district, but know the former customers and how to deal with their various idiosyncrasies. A sum of money is usually paid for "goodwill," but if the incomer takes over the whole stock at a valuation this should not be large, as he is sinking a good deal of money in goods which it will be difficult to realise.

Profits. The beginner will be told that he will make a profit of from 25 to 30 per cent. on the "turnover," and he enters on his new business with rose-coloured dreams of quickly amassing a fortune. He will not be long in business, however, before he finds out that he has got to modify his ideas on that score very considerably, and he will have to be content with something a good deal less than half the lowest sum named. If he is ambitious of doing a big business and goes in for estimating, he will be fortunate—if he does the work honestly, and we presume he will—if he lifts the order with a margin which will leave him a clear profit on the transaction. Here, as in every other business, it is experience that tells.

Some articles in the stationery trade have for some time been so keenly cut by certain traders that they could only be handled at a loss in any attempt at competition. This led recently to the formation of what is called a Proprietary Articles Protection Association, composed of stationers, wholesalers, and manufacturers, under which an arrangement has been come to whereby certain specified articles supplied by the members of the association shall not be sold below a given price, thus allowing a fair working margin of profit to the retailer who handles the articles.

Shop Arrangement. Goods should be arranged methodically; octavos of foolscaps, posts, large posts, and mediums by themselves; quartos of the various sizes by themselves. Business books should be similarly treated. A few glass cases are a decided advantage, and add to the appearance of the premises. In these, the finer bindings and "West-end books," and a few of the more expensive inkstands and stationery cases can be shown. Notepaper and business papers should also be arranged according to quality and size. The various papeteries and mourning stationery should have their own place. In fact, the stock should be departmented—those articles most in demand nearest to hand, and everything arranged so that the shopkeeper may be able to find a given article even in the dark. The employer should insist on each department being kept tidy—with someone responsible for it, and should on no account tolerate broken parcels. As most notepaper and envelopes may now be had boxed, it is not difficult to follow these directions.

All goods coming in should be immediately unpacked, checked with invoice, and carefully marked with cost price in private mark and selling prices in plain figures. Of course, it is a matter of no moment whether the selling price should be marked in private or plain figures, but most buyers prefer to be able to see for themselves the price of the article they are purchasing. The goods should be carefully assorted in the stock-room and the front shop replenished when necessary, care always being taken that those goods which are in daily demand shall not be allowed to run out. It is always good policy to see that one parcel of any given article shall always be left in the stock-room.

The Windows. The windows ought always to be clean and attractive, and changed often. A good idea is every now and then to have what is called a "one-article window." This, for instance, might take the form of an effective display of papeterie in various sizes, with the stationer's own name and address printed on them. These should always be of good material and extra value. As he has a permanent advertisement in the boxes he should be content with a very small margin of profit. If the contents of the papeterie please his customers the chances are that he will not only have repeat orders, but have the satisfaction of selling other goods as well. Make a point of discarding cheap and nasty stuff and of supplying only the best value possible. This is the best way to keep on good relations with customers and to build up a business on a sound and solid basis. Allow your name to appear on nothing that is not really first class. The advertisement is permanent whether for good or evil.

On another occasion the stationer may make a show of business books. If, for instance, he has secured a specially good order for a set of business books from some large firm, he may put them in the window for a day or two, taking care that the titles of the books and the name of the customer for whom the order is being executed are not exposed to the public.

Fountain Pens and Typewriters. Then, again, in fountain pens there is a large and ever increasing business being done. These, as a rule, afford a fair margin of profit, and the best of them come under the rules of the Proprietary Articles Association. While they should always be well forward both in the window and on the counter of the up-to-date stationer, a "one-article" window of them might occasionally be made. Of course, a hundred pounds will not go far in this way: but it will pay to make now and again a good display of them. Without offensive pushing they can be turned into a good source of revenue. It is a good plan always to have one or more in your own pocket which you can allow your customer to try—one that you are using daily, and therefore ready to write the moment it touches paper. If the pen you are in the habit of using does not suit your customer, another from stock can easily be substituted.

The typewriter is usually handled by specialists; but there is no reason why the stationer should not now and again dispose of a machine. There is money in the business. He has a typewriter, as a rule, for his own use. Why not get an agency and keep beside him a good supply of attractive catalogues which he might judiciously use to good purpose? At any rate, there is no reason why the papers, ribbons, carbons, etc., necessary for the manipulation of the typewriter should not be supplied by the stationer. A small stock of these articles can easily be got. They are usually supplied in neat, cardboard boxes, and can, therefore, be tidily kept and easily handled. If a trade is done with law or commercial houses, a book of samples might be taken round and shown, and prices quoted—in fact, neat booklets of samples can be obtained for distribution. These can be stamped, or, what is better, have printed the stationer's name and address. This will lead to increased business. Do not be above going out and pushing your business.

Letter-presses are sold only occasionally, and a large stock of them need not be kept. One or two should be stocked, however, to show styles and to be ready in case of emergency. Orders can be taken from makers' lists.

Die-stamping. Die-stamping forms a large and fairly profitable part of the stationer's business, and it is one which he will do well to cultivate. A good many wholesale houses now issue books of samples, showing qualities of paper and styles of stamping both in "plain" and "relief." Some enterprising firms even go the length of cutting the die free—charging only for the stamping—trusting to recoup themselves for their initial outlay by repeat orders. As there is something attractive and in decided good taste about a neatly stamped note heading, most customers—who would never think of going to the expense of getting a die cut—for the extra charge of, say, a shilling, would be glad to place an order for five quires of notepaper and 100 envelopes. Then, as this trade develops, the stationer will naturally find that he can do with a much smaller stock of notepaper and envelopes. This will liberate a certain amount of capital and allow it to be otherwise employed. Of course, this question opens up a wide field of enterprise which can easily be exploited by the stationer who is alive and knows his business. For instance, there is the interesting subject of wedding stationery, including invitation and complimentary cards; at-home, with menu and guest cards; dinner, dance, and visiting cards; and the perennial, and ever increasing trade in Christmas cards. Show cards—tastefully and artistically arranged—of these can and ought to be exhibited, and the makers' books kept handy for reference, or to bring under the notice of likely customers. Business printing and lithography may be manipulated in the same way by arrangement with lithographers and printers who work for the trade.

Wholesale Houses. A word as to wholesale houses. While there is truth in the saying that it is not good policy to keep all your eggs in one basket—and a comparison of prices is good for all concerned—at the same time, if you have confidence in your wholesaler, and know that he is doing his best for you, you will do well not to multiply accounts. You will not be long in business before you find out that one firm is best for paper; another makes a special feature of envelopes; while a third does business books at a price which the others cannot touch. You ought, above all things, to exercise the greatest caution in taking up "specialities" shown by entire strangers who exhibit an undue anxiety to do you a special favour by making you "sole agent" in the district for their wares, on condition, of course, that you place a good order for a stock of the article. If you do, you may find that others have also been made "sole agents," and that more than one stationer has been landed with articles of which he will find some little difficulty in getting rid. As a rule, you can get "the latest novelty" from one or other of the wholesale houses with whom you deal.

TECHNICAL DRAWING
continued from
page 5168

By JOSEPH G. HORNER

To Mark Out in Four Pieces a Tapering Elliptical Article. In this the taper at ends and sides are unequal. Fig. **136** shows the depth, and **137** the plan. In **137** there are two ellipses concentric with each other, but marked from separate sets of centres. Fig. **139** is a pattern of the side, obtained as follows: From the point 3 [**137**], which is the centre from which the larger curve of the outer ellipse is struck, draw the vertical line 3 4, and continue the large curve round to meet it at 4. Draw the horizontal line 4 5 from 4, making its length the same as the vertical depth of the article 1 2 [**136**]. From the point 5 draw the line 5 6 at right angles to 5 4, the distance from 5 to 6 being the distance between the sides of the outer and inner ellipses at 1 2 [**137**]. From the point 6 thus obtained draw a line passing through 4 to 7, where it meets the centre line 1 8. The distance from 4 to 7 will be the radius of the outer curve *a*8*a* [**139**], the centre of which is located at 9. The inner radius of the side is obtained in the same manner as the outer, by projecting the vertical line 10 4′ [**137**] from the centre 10, from which the curve is struck, until it intersects a continuation of the curve itself at 4′. The depth of the article is again marked from it at right angles, giving the line 4′ 5′; and again at right angles from the end 5′ of this line the distance 5′6′ is set off, representing the distance 1 2 [**137**] between the sides of the ellipses in plan. Through the points 6′ and 4′ thus obtained a line is projected to 11 on the centre line 1 8. The distance from 6′ to 4′, or 6 to 4, is set off from 8 to 12 [**139**], giving the width of the segment. Then with the distance 4′ 11 as radius the inner curve [**139**] is struck through 12, its centre being at 13. The length of this segment comes halfway between the centre lines of the two ellipses at the point 14 [**137**], the distance 1 14 being taken from and set off on each side of the centre line at 8*a*, 8*a* [**139**]. From the length of curve thus obtained radial lines are drawn to the point 13 on the centre line, and the marking out of the segment for the sides of the article is finished.

The end piece [**138**] is struck in a similar manner from the ends of the ellipse. The horizontal line 15*b* [**137**] is projected from the centre 15, from which the end curve of the inner ellipse is struck, until it meets the dotted continuation of the end curve at *b*. The line *bc* is drawn at right angles from *b* 15, its length, *bc*, representing the depth of the article 1 2 [**136**]. A line at right angles therewith from *c* to *d* represents the distance between the inner and outer end curves of the ellipse, 16 to 17 [**137**]. A line is drawn through the points *db* to cut the centre line at 18. The distance from 18 to *b* is the radius of the inner curve [**138**], struck from the centre 13. The width of the segment is taken from *d* to *b* [**137**], and set off from 11 to 19 [**138**]. The radius of the outer curve at 19 [**138**] is obtained by projecting the horizontal line [**137**] from 18, the centre from which the outer curve is struck, to *b′*, where it meets the dotted continuation of the curve. The perpendicular from *b′* to *c′* is the same length as 1 2, on **136**, and the horizontal from *c′* to *d′* is the same length as the distance between the ellipses 16 to 17 [**137**]. A line drawn through *d′b′* gives the point where it cuts the centre line, and from that point to *b′* is the radius with which the outer curve of **138** is struck. Its centre is at 20, which is fixed by the width of the segment, obtained either from *db* or *b′d′* [**137**]. The length of the segment is measured from 17 to 14 [**137**], and set off on each side of 19 in **138**, 19*e*, 19*e*.

To Describe the Pattern for a Canister Top. This tapers from an ellipse to a circle. Fig. **140** is the elevation, **141** the plan, and **142** the development of the pattern in one piece. Draw on the plan a diagonal line 3 2 between the points where the end and side curves intersect. Then in **143** draw a centre line 1 0, and two transverse lines at right angles therewith at the same distance apart as those representing the depth of the article 1 1 [**140**]. Transfer the length 2 3 from **141** to the line 2 3 [**143**], and also the diameter of the hole 4 5 to the line 4 5 [**143**]. Project lines through 2 4 and 3 5 to cut the centre line at *o*. With *o*2, or *o*3, as radius strike the curve 2 3 [**142**] from centre *o*. Returning to the plan [**141**] draw a perpendicular from 6, which is the centre from which the side of the ellipse is struck, and continue the curve of the side round to meet it at 7. Draw a line at right angles with 6 7 from 7 to 8, of the same length as the depth of the article 1 1 [**140**]. Draw another line at right angles with 7 8, from 8 to 9, making its length the same as the width of the side, 4 to 10 [**141**]. Then produce a line from 9 through 7 to cut the transverse centre line at 11. With 11 7 as radius strike the arc 2 3 [**144**], and draw the perpendicular *o*1 through the centre *o*. Divide half the length of the side, 3 to 23 [**141**], and mark off the same number of divisions each side of the centre 1 on the curve 2 3 of **144**. Draw also the radial lines 3*o*, 2*o*, and the chord 2 3.

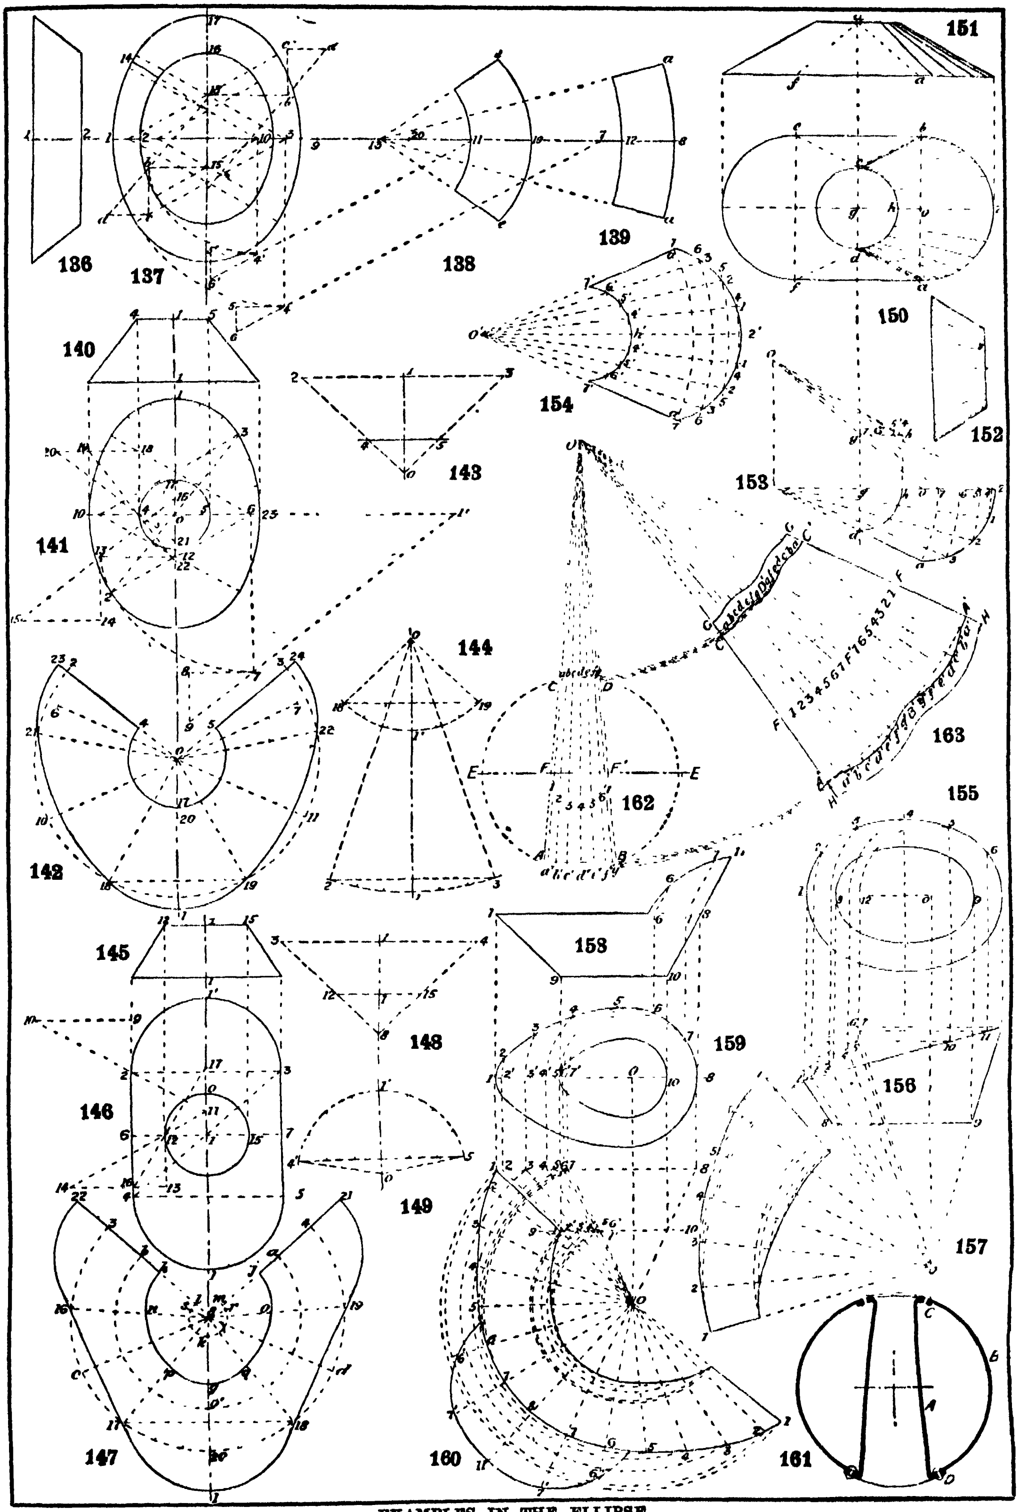
Next, from 12 on the plan [**141**], which is the centre from which the end curve is struck, project a horizontal line to meet an extension of the curve at 13. Draw a line at right angles with 12 13, from 13 to 14, corresponding in length with the depth 1 1 [**140**], and then another line at right angles with this, from 14 to 15, corresponding in length with the width of the end, 1 to 17 [**141**]. Project a line from 15 through 13 to cut the centre line at 16. With radius 16 13, and from *o* [**144**] as centre, strike the arc 18 19. Measure the end curve [**141**] from 1 to 3, and transfer its dimension to each side of the centre 1′ on the curve 18 19 [**144**]. Draw radial lines from 18 and 19 to the centre *o*, and also the chord 18 19. Transfer the length of the latter to the chord 18 19 [**142**], cutting the boundary circle 2 3 at 18 19. With the radius *o*18, from **144**, strike the arc 18 to 19 [**142**], its centre being on the centre line at 20, and its ends coinciding with the intersections of chord and circle at the points 18, 19. Then take the chord distance from 2 to 3 [**144**] and transfer it from 18 to 21, and from 19 to 22, intersecting the boundary circle. Bisect these lengths at 10 and 11, and project lines from all these points to the centre *o*, extending the lines from 10 and 11, through *o*, to the points 7 and 6 beyond respectively. The points 6 and 7 are the centres from which the curves 21 18 and 22 19 are struck, the radius being taken from *o* to 1 [**144**]. Next measure the length of the boundary circle from 18, or from 19, to the centre line 1′ [**144**], and transfer the same from 21 to 2, and also from 22 to 3 [**142**], and draw the radial lines 2*o* and 3*o*. Then with the radius 20 1 [**142**], from which the curve at the base is struck, describe the arcs from 21 to 23, and from 22 to 24, the centre in each case being on the radial line which marks the end of the pattern. This finishes the development of the exterior of the pattern and leaves the circular hole to be marked out.

Draw on the plan [**141**] a vertical line from 4 to 18, corresponding in length with the vertical depth of the article, 1 to 1 [**140**]. From 18 draw a line at right angles with 18 4, through 19 to 20, the distance from 18 to 19 corresponding with the dimensions from the edge of the circle to the ellipse, or 4 to 10, and the distance from 18 to 20 corresponding with a similar measurement lengthwise, or 17 to 1. From 19 and 20 draw lines through 4 to cut the centre line at 22 and 21 respectively. Take the length from 20 to 4, which is the slant of the end, and mark it off on the radial lines of **142**, from 23 to 4, 1 to 17, and 24 to 5, thus obtaining the points 4, 5, 17, through which the curve for the hole is struck. Then with 4 21 from **141** as radius, describe arcs through these points, the one which cuts 17 being struck from the centre line *o*1, and finishing where it cuts the radials *o*18 and *o*19; and the arcs from 4 and 5 being half the length, struck from the lines *o*4 and *o*5, and ending at the radials 21 and 22. The centres from which these three arcs are struck are too close to the common centre *o* to be distinguished by separate numbers. The connection between these arcs is now completed by taking the radius 4 22 from **141**, and joining them with arcs of this radius struck from centres on the lines 6 11 and 7 10 [**142**].

To Describe a Tapering Neck with Parallel Sides. This has semicircular ends, and a circular hole in the top. Fig. **145** is the elevation and **146** the plan of the article. Fig. **147** is the development in one piece, with the joint at one end. Through the centres of **145**, **146**, and **147**, a perpendicular line 1 1 is drawn. In the plan [**146**] there are three horizontal lines, 6 7 being central, while 2 3 and 4 5 pass through the centres from which the end semicircles are struck. To proceed with the development, extend the line of one side, in **146**, to the point 9, the distance from 2 to 9 being the same as the vertical height 1 1 [**145**] of the article. Draw a line at right angles with 2 9, from 9 to 10, the distance between 9 and 10 being taken from *o* at the edge of the hole to 1′ at the semicircular end, thus representing, in plan, the taper from hole to end. Draw a line from 10 through 2 cutting the centre line 1 1 at 11. From the point 12 on the circle representing the hole draw a line to 13, the distance between 12 and 13 representing the depth of the article 1 1 [**145**]. Take the distance from *o* to 1′ as before and transfer it to the horizontal line 13 to 14. Then draw a line from 14 through 12 to 11, where the centre line is cut by it. In this case the diagonals both from 14 and from 10 happen to meet at 11, but with different proportions they would cut the centre line at different points. Next, in **148**, draw horizontal lines 3 4 and 12 15, at distances apart, 1 1, corresponding with the depth of the article, 1 to 1 [**145**]. Draw the centre line 1 8 [**148**] at right angles with these lines, and on the upper horizontal line mark off on each side the distances 1 3 and 1 4, corresponding with 1 3 and 1 4 on the diagonal line in **146**. On the lower horizontal line [**148**] mark off the diameter of the hole 12 15, similarly numbered on the other views. Through these four points, 3, 12, and 4, 15, draw the diagonal lines cutting the centre at 8, as shown in **148**. With 8 3 or 8 4 as radius, strike the large boundary curve 3 4 20 from the centre 8 [**147**].

Now, with radius 1 12 [**146**] strike the curve 4′ 1′ 5′ from centre *o* [**149**]. By stepping round with dividers, make the length of this curve similar to the length of curve in one of the semicircular ends in **146**, and draw the chord 4′ 5′ [**149**]. Draw a chord of similar length across the lower part of the boundary curve in **147**, giving the points 17 and 18. From these points, with dividers set to the radius *o*4′ or *o*5′ [**149**] mark off the point *o*′ on the centre line of **147**. With *o*′ as centre, strike the curve 17 1 18, corresponding with the curve in **149**. Next take the length of the side, 3 5 in **146**, and mark it off from 17 to 16, and from 18 to 19, in **147**, intersecting the boundary curve. Draw lines from these points to the centre 8. Then, from the centre 8 strike a curve through the point *o*, giving the points *a* and *b* whence the radial lines to 21 and 22 are drawn. The points *a* and *b* are centres from which the curves 22 16 and 21 19 are struck, their radius being the same as the curve struck from *o*′ in the lower part of the view. The pattern of the outside is now completed by connecting the curves by the tangential lines 16 17 and 18 19.

For the development of the round hole in the top, bisect the line 16 17 at *c*, and 18 19 at *d* [**147**] and produce them to *r* and *s* respectively. Take the length 14 to 12 [**146**] and set it off in



EXAMPLES IN THE ELLIPSE

136-139. An ellipse with unequal taper **140-144.** Elliptical figure tapering to a circle **145-149.** An object the ends of which form conic frusta **150-154.** Another method of development **155 157.** An elliptical figure with unequal slant **158-160.** Development of an oval bath **161-163.** Development of plate for conical tube

147 from 1 to *g*, 22 to *h*, and 21 to *j*. Take also the distance 11 to 12 in **146**, and in **147** set it off respectively from *g* to *k*, *h* to *l*, and *j* to *m*; *k*, *l*, and *m* are centres whence are struck the curves *hn*, *jo*, and *pgq*. The radius of the connecting portions is obtained by drawing in **146** the diagonal line between points representing the depth of the article and the slant of the side, and prolonging this line to the point 17, the distance from 17 to 12 being the radius required. The centres in **147** are located at *s* and *r* on the prolongation of the bisecting lines *c* and *d*.

Another Method. Problems of this and allied kinds may be approached, and rendered more obvious perhaps, by regarding them directly from the point of view of the cone. Thus, in **150**, **151**, **152** the shading introduced shows that the ends of the articles must be portions of oblique cones, the construction of which has been explained on page 4737. The point is, that the base can be divided round into any number of equal parts, and lengths taken from those divisions to the apex, through which points the required curve can be drawn, and the plane of truncation can be treated similarly.

Looking now at **150** and **151**, we can regard the article (irrespective of the question of actual jointing up) as formed of segments only of conic frusta, meaning by that that the cylindrical shapes are incomplete. They terminate at *a*, *b*, *c*, *d*. They are connected with plane triangular pieces *a*, *d*, *f*, and *b*, *c*, *e*. Fig. **153** shows the method of development.

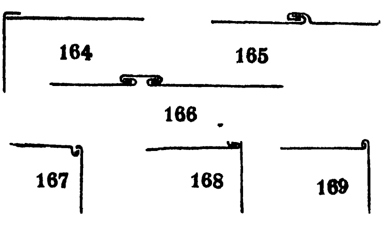
Draw a horizontal line 1′ 2′. Set off a centre *o* from 2 in **150**, and with the same radius describe the quadrant 2′*a*, equal in length to 2*a* in **150**. Step round on it any convenient number of chord lengths, 2′, 1, 2, 3, *a*. Set off on the line 1′2′ the distances 2′*g* and 2′*h*, corresponding respectively with the centre of the round hole and its edge, in **150**, and raise perpendiculars therefrom. Draw a horizontal *g*′*h*′, corresponding with the plane of the top of the article. Draw lines through 2′*h*′ and through *og*′ prolonged, to intersect at the centre *o*′, which locates the apex of the oblique cone, and drop the perpendicular *o*′1′. From 1′ describe arcs from 1, 2, 3, *a*, to intersect the line 1′2′ in 4, 5, 6, 7, respectively. Connect these points with the apex *o*′, cutting the plane *g*′*h*′ at 4′5′6′7′. Next take the slant length *o*′2′ [**153**], and set it off from *o*′ to 2′ [**154**]. Similarly, take successive radii, *o*′4, *o*′5, *o*′6, *o*′7, and set them off in **154** as shown by corresponding references. Take the successive equal divisions, 2′1, 1 2, 2 3, 3*a*, in **153**, and step them round from 2′ to 1, 2, 3, *a*, in **154**, and draw lines through the points of intersection to the centre *o*′. A curve drawn through these points of intersection 2′, 1, 2, 3, *a*, repeated on the other side of the centre line will give the development of the curved base of the truncated cone. For the round hole in the top, complete **154** thus:

Take successive radii from *o*′ [**153**] measuring thence to *h*′, 4′, 5′, 6′, 7′, and transfer to **154**, cutting the radial lines at *h*′, 4′, 5′, 6′, 7′, repeated on each side of the centre line. These will form the points of intersection through which the curve is drawn.

To Mark Pattern for an Elliptical Object with Angles Constantly Changing. Fig. **155** is the plan of the object, and **156** the elevation. In plan, the taper appears equal all round, but in elevation the angle is seen to vary, because the back is higher than the front. In **156**, project the lines 7 9 and 1 8, till they meet at the common centre *o*. From *o* carry a perpendicular up to *o* on the centre line 1 7 of **155**. Divide one half of the outer ellipse into any number of parts, as 1, 2, 3, 4, 5, 6, 7. With *o* on the line 1 7 as a centre, strike arcs from 2, 3, 4, 5, to cut the line 1 7. An arc from 6 [**155**] would coincide with the one from 5, and also one from 7, and the extreme points 1, 7, coincide with the points 1 and 7 on the elevation [**156**]. Drop a perpendicular direct from 5 on the ellipse to 10 on the line 1 7 of **156**, and another from the point 12, where the arc from 5 on the ellipse cuts the centre line 1 7, stopping the latter perpendicular at 5 on **156**, which is the point where a horizontal from the intersection 10 of the first perpendicular and the sloping line 1 7 occurs. From the point 5 draw a sloping line to 1. Draw also a horizontal from 7 to 7, and another from 6 to 11, which is the point on the line 1 7 where a perpendicular from 6 [**156**] cuts it. We have now points 1, 2, 3, 4, 5, 6, 7, on **156**. From each of these draw a radial line to the centre *o*, and then with *o* as a centre describe curves of indefinite length from each of these points on the upper part of **156**, and also from each of the radial intersections on the line 8 9 of **156**.

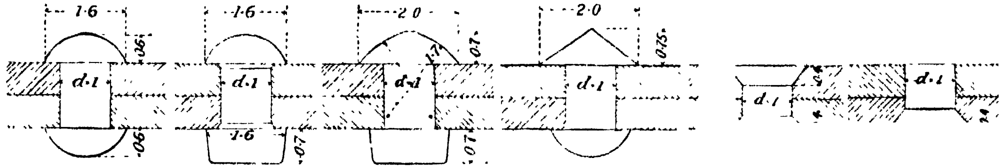
Draw now the line 7*o*, of **157**, clear of the lines of the elevation, and then with dividers set to the divisions on the ellipse [**155**], step from 7 [**157**] to 6, and so on till the point 1 is reached, beginning on the outer circle 7, and stepping across from one circle to the next till, at the point 1, the inner circle of the same number is reached. Through these intersections the outer line of the pattern is drawn. The inner line is traced through the intersections of radial lines with the inner set of curves, stepping as before from one circle to the next, the widest part of the pattern being at the end 7*o*, and the narrowest at the end 1*o*. This gives the pattern for one half of the object.

To Strike in One Piece the Pattern for an Oval Hip-bath. Fig. **158** is the side elevation, and **159** the plan. The shape of the inner oval is decided by the position of the points 5 and 10 on the centre line, and need not be drawn. In **160** draw the two horizontal lines 1 8 and 9 10, at the same distance apart as the top and bottom lines similarly numbered in **158**. Project perpendiculars from 1, 5, 10, 8, on the centre line of **159**, to the upper line 1 8 [**160**], continuing those from 5 and 10 to the lower line 9 10. Draw lines from 8 and 1 through 10 and 1′ [**160**] to meet at the centre *o*. Project a perpendicular up from *o* to *o* on the centre line of **159**. Then divide the upper half of the outer oval [**159**] into any convenient number of parts, as 1, 2, 3, etc., and from the centre *o* on the same figure describe arcs from each of these points to cut the centre line 1 8 at 2′, 3′, etc. From these points, similarly numbered on the line 1 8 [**160**], continue lines converging to the centre *o* and cutting the line 9 10 in 1′, 2′, 3′, etc.

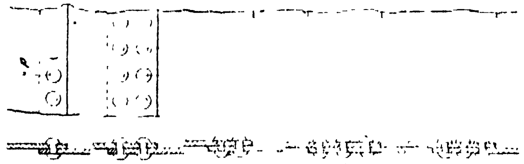


VARIOUS SEAMS AND ROLLED JOINTS

With *o* as a centre now describe curves of indefinite length from each of the intersections, both on the line 1 8, and the line 9 10, as shown in **160**. Then, with the dividers set to the divisions round the oval in **159**, start from 1 at the end of the line 1 8 [**160**], and step off round the curves the same number of divisions, crossing the curve 1 to 2, 2 to 3, and so on at each step until the centre line is reached, where the number of steps has amounted to the same as those round half the oval in **159**. Then proceed with a similar number to complete the other half, but working across the curves in the opposite way, so that the final step occurs again on the outer circle at 1 on the lower right-hand side of **160**. From each of these points of intersection draw radial lines to the centre *o*, which will give the correct points of intersection on the inner set of circles from the line 9 10. Through these intersections trace the outer and inner lines of the pattern.

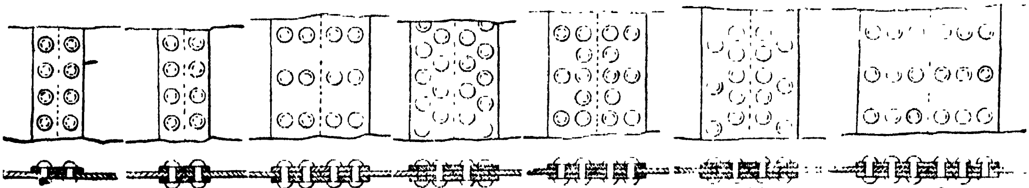


PROPORTIONS OF RIVETS



FORMS OF LAP-RIVETED JOINTS

To obtain the shape of the back, draw perpendiculars from 6′ and 7′ [**159**] to the line 1 8 [**158**], and thence continue them parallel with the back, 10 11, till they cut the curve (which has previously been decided on) at 6 and 7. Take the distance 8 to 11 and mark off the same from 8 to 11 at the back of the pattern in **160**. Take also in turn from **158** the distances 6 to 6′ and 7 to 7′ from the curve to where they cut the horizontal, and mark off these lengths from the points similarly numbered on each side of the centre 8 on the outer curve of the pattern. Through these points trace the curve 6′ 7′ 11.



FORMS OF BUTT-RIVETED JOINTS

Conical Tube. Fig. **161** A is a common fitting, the well-known conical, or "Galloway" circulating tube. It is fitted both into the furnace flues of horizontal boilers, and the fireboxes of vertical types. Fig. **161** shows it as fitted in a parallel flue. The tube A is thrust through the larger hole of the furnace B, which is large enough to allow the flange C to clear. The flanges C and D are secured by riveting.

As the tube is of sensible thickness—from $\frac{1}{4}$ in. to $\frac{3}{8}$ in.—the dimensions correspond with the external diameters after bending and welding. These diameters are AB and CD [**162**], and the diameter of the furnace flue is indicated by the circle EE. Lines are projected through AC and BD to a point *o*, where they meet, which is the apex of the cone of which the water tube is a frustum. As the flanges fit a cylinder, the regular curves of some previous developments are unsuitable. The varying curves required are obtained on lines of equal division stepped round the conical body as at FF′. A half circle is divided round F, 1, 2, 3, 4, 5, 6, 7, F′. Draw lines through these points from *o* to cut the circle of the furnace flue in *a*, *b*, *c*, *d*, *e*, *f*, *g*, on the smaller end, and at *a*′, *b*′, *c*′, *d*′, *e*′, *f*′, *g*′, at the larger end. From the points where these lines of division on the cone cut the circle of the furnace EE draw radii from *o* as a centre to **163**, which shows the development of the plate.

In **163** draw a centre line oB', and to right and left of it set off the length $B'A'$ equal in length to the circumference of the large diameter AB of the tube in **162**, and divide the length into twice the number of equal parts of the half circle in **162**, $A'\ a'\ b'\ c'\ d'\ e'\ f'\ g'\ B'\ g'\ f'\ e'\ d'\ c'\ b'\ a'\ A'$ [**163**]. Draw lines thence to the apex *o*. At the points where these radial lines intersect the curves drawn from **162** draw the outlines of the plate as indicated by the similar references. The middle plane FF might be divided instead of the end, as indicated. Beyond these outlines add sufficient for flanging—namely, the lines GG, HH.

Joints. A very condensed account of joints must now conclude this course.

Joints in sheet and plated work are made by soldering, brazing, welding, lapping, or rolling simply, and by riveting, and bolting.

With regard to the additions made, these are generally of the character shown in **163**—that of supplementary width added to the edge or edges of the developed outline. But in many cases the joint has to be made somewhere in the body of the development.

Soldering and Brazing. The joints for union by these methods are of various kinds. The commonest is the lap. Edges are sometimes thinned down to a *feather edge* before lapping in order to maintain an even thickness. The thinnest sheets are generally left untouched, which leaves a slight thickness or angle to be occupied by solder and assist the holding of the solder in the joint faces. Abutting joints are not used much for soft soldering, though rather more frequently for brazing. But the small area of the parts in contact prevents making a strong job.

A good many joints at right angles are made by abutting joints, because an angle of solder can be run down the internal angle as well as between the faces. But all strong joints must have considerable surfaces for the soldering material to adhere to. An example of this kind was illustrated in the cramped joints of the coppersmith [page 3884], which are made in joints in one plane, in curves, and at right and other angles. In work in tin, zinc, and lead other kinds of lap joints are common, such as lapping and rolling.

Fig. **164** shows a plain angular joint in which the edge of one sheet is bent over to cover the edge of the sheet adjacent, and soldered. Figs. **165** and **166**, show two forms of lap joints made watertight without soldering, the seams being closed by hammering. Fig. **167** shows an angle joint that must be soldered, otherwise it could be pulled apart. Figs. **168** and **169** are other forms which may be soldered or not. Figs. **170** and **171** are roll joints for lead and zinc respectively, which need not be soldered.

Welding. Welding has been described under **Smiths' Work** [see page 2988]. It is a process employed for pieces of sensible thickness, as bars, rods, sections, and plates, but not for thin sheets.

Riveting. To discuss all the points in connection with riveted joints would cover a very wide field. We must be content to show the forms of rivets and the more important types of joints. The commonest type of rivet used by engineers is the *cup-head*, or spherical head rivet [**172**] In this both head and tail are alike. In **173** the tail is still of the cup section, but the head is of the *pan* shape, which is stronger. In **174** the head is of pan shape, but the section of the tail includes two curves, *conoidal* head; **175** is the conical tail formed by hammering only. In each of these the head and tail stand beyond the faces of the plates. When this is objectionable *countersunk* rivets are used [**176**]. Sometimes one end only is countersunk, as in **177**. Proportions vary slightly, but those given in the figures show average practice. In each case the unit is the diameter, *d*, of the stem, or *shank* of the rivet.

The numerous forms in which riveted joints occur are not determined arbitrarily. Joints in the same plane are as follows: *Lap* joints *single riveted* [**178**]. These are the weakest forms. A stronger joint is made by *double* riveting, and this may be of *chain* type [**179**], or *zig-zag* [**180**]. In some cases *treble* riveting is used, either of chain type [**181**] or zig-zag [**182**]. The objection to all these is that the plates are not in the same plane. The method is suitable for uniting belts of plating in cylindrical boilers, *circular* seams, but not for longitudinal seams, which would develop grooving. Hence the superiority of the *butt* joints. In these, plates which abut in the same plane are riveted through a covering strip, or strips, *butt strips*, or *straps*. *Single butt straps* [**183**] are used, or *double butt straps* [**184** to **189**]. A strap on each side makes a better job than a strap on one side only. As in lap joints, the rivets are arranged in single lines, *single riveting* [**183**, **184**], in two lines, *double* riveting [**185** to **188**], or in three lines *treble* [**189**], and also as chain and zigzag riveting as illustrated.

Close and Open Riveting. The whole of the proportioning of riveted joints is a compromise between the strength of the plate left between the rivet holes, and between the edges of the holes, and the edges of the plates for butt straps, and between the tightness of the joint to resist steam or water pressure. To lessen the loss of strength consequent on making the holes for the rivets, the spacing is increased. But for tightness of jointing the spacing should be lessened. This explains the zig-zag riveting, in which provision is made for leaving the plates with the maximum strength possible, and close joints, and the reason for the close and open riveting in **187** and **188**. This also explains why the spacing for steam boilers and vessels subject to hydraulic pressure always is closer than that for bridge and girder work.

The pitch of rivets, *p*, in the figures is the distance between adjacent centres. In no case should this be less than enough to leave a space equal to the diameter of the rivet between adjacent holes, and it is generally more. The same rule holds with regard to the width of metal left between the edge of a hole and adjacent edge of the plate, or the covering strap. In zig-zag riveting the diagonal dimensions must fulfil the same conditions, and not the spacing between the rows.

THE TRANSMISSION OF POWER

Shafting, Pulleys and Belting. Rope Driving. Bevel and Cog-wheel Driving. Transmission of Power by Hydraulic and Pneumatic Agencies

Group 24
POWER
3

Continued from page 5128

By F. L. RAWSON

NOT only is it almost invariably the case that power has to be transmitted from the place where it is produced to some other place where it is utilised, even within the confines of a single factory or works, but it is becoming more and more usual to concentrate the generation of power at central points and thence to distribute it to consumers of all classes within a radius which may vary between a few yards and many miles. It is evident, therefore, that means must be provided for transmitting the power, to suit the very diverse conditions met with. The principal methods may be classed under the following heads: mechanical (shafting and gearing); electrical; pneumatic; and hydraulic. Steam and gas are also used, though they come under a slightly different category. The former can be employed only over comparatively short distances, and is so wasteful that it may be set aside at once; but the latter is excelled only by electricity in point of the range covered.

Shafting. Shafting constitutes the most elementary means of power transmission, sometimes being the only means, as where the engine is coupled direct to the driven machine by a piece of shafting, short or long. Locomotives, steamships, pumping engines, steam-dynamos, ventilating fans, and many other kinds of machinery are almost invariably constructed in this way, and often the counter-shafting in large workshops is driven directly from the engine. Shafting, however, can be economically employed only over distances not exceeding about 300 ft., owing to the friction, torsion, and other disadvantages attending its use. Except in very short lengths, it must be perfectly straight, and where the power is to be carried round a corner, bevel gearing or belts must be employed, with the accompanying increased cost of installation and maintenance, and loss of power. On the other hand, it is rarely economical to drive every individual machine in a factory or workshop by independent means, and therefore short lengths of shafting, each driven by a separate motor (nowadays, almost always an electric motor) and driving a number of machines, are the general rule. Mild steel shafts are used, running at speeds usually between 100 and 300 revolutions per minute; the principal dimensions, etc., are obtained from formulæ such as the following:

Horse-power transmitted:

$$\mathrm{HP} = \frac{1}{70}\,\mathrm{D}^3\mathrm{N}.$$

Diameter of shaft:

$$\mathrm{D} = \sqrt[3]{\left(\frac{70 \times \mathrm{HP}}{\mathrm{N.}}\right)}$$

Space between bearings:

$$\mathrm{S} = 5\,\sqrt[3]{\mathrm{D}^2}.$$

where HP = the horse-power to be transmitted,
N = the number of revolutions per minute,
D = the diameter of the steel shaft in inches,
S = the space between bearings, in feet.

If a wrought-iron shaft is used the diameter must be increased, for the same horse-power, by 15 per cent. The foregoing values apply to mill shafting carrying pulleys for belt driving, etc. For pure transmission of power, without bending stresses, lighter shafting may be used. The loss of power in friction due to shafting depends enormously upon the attention given to the bearings, both in erection and in upkeep, and is seldom less than 25 per cent. of the power applied, often more than 50 per cent.

Belting and Pulleys. The most convenient and usual method of taking power off shafting is by means of leather belts running on pulleys. The pulleys are preferably made in halves, so that they can easily be mounted on the shaft without disturbing the latter, and are usually made of cast or wrought iron, the latter especially when the pulleys are large. Large numbers of wooden pul'eys are also used. The faces of the pulleys are slightly rounded, the greatest diameter being in the middle, for use with plain belting, this device keeping the belt in position; but wrought-iron pulleys are often cylindrical, and so are pulleys used with link belting. They are fixed on the shaft with keys, fitting between a flat filed on the shaft and a key-way provided in the boss of the pulley, but split pulleys can be fixed sufficiently tightly, as a rule, by means of the bolts which hold the halves together, without the use of keys. The ratio of the diameters of driving and driven pulleys should not exceed 6 : 1, and the distance between centres should be such that the arc of contact of the belt on the smaller pulley is never less than 150 degrees, greater if possible. Vertical or steeply inclined belts should be avoided.

Theory of Power Transmission by Belting. Leather belting is most commonly used, though cotton belting is also very satisfactory. Single leather belts are about 0·25 in. thick, and the width varies according to the power transmitted. The speed of the belt, which is practically equal to that of the pulley rim, is an important factor, as the higher it is the greater is the power that can be transmitted. A limit is set to this, however, by the action of centrifugal force, which renders it undesirable to employ a speed higher than 5,000 ft. per minute. When the power is greater than can be dealt with by means of a single belt, a double belt is used, about 0·4 in. thick. Still stronger belts are made up of leather links, laid on edge side by side, and joined together with steel pins, which act as hinges. The power transmitted is proportional to the difference in tension between the two sides of the belt, and the tight side is generally subject to about twice the tension of the slack side. The weakest part of a belt is the joint; allowing for this, the safe working tension in the tight side is 300 lb. per square inch of cross section, and the useful pull transmitted is 150 lb. per square inch, or 37·5 lb. per inch of width of a single belt, and 60 lb. in the case of a double one. The following formulæ apply to single and double leather belts, of 0·25 and 0·4 in. thickness respectively:

Horse-power transmitted by belts:

$$\text{Single: } HP = \frac{3}{10{,}000} \times WDN,$$

$$\text{double: } HP = \frac{4{\cdot}8}{10{,}000} \times WDN,$$

where W = width of belt in inches,
D = diameter of pulley in inches,
N = number of revolutions of the *same* pulley per minute.

The velocity of the belt is given by the formula:

$$V = 0{\cdot}26 \times DN$$

where V = velocity in feet per minute.

be taken as approximately equal to that of a double leather belt. Cotton belts come between single and double leather belts in point of strength. It must be added that different thicknesses can be obtained in each case, and the foregoing formulæ strictly apply only to the average values; differences in the ratios of tensions in the two sides of the belt, in the arc of contact, etc., also enter largely into the determination of the safe load of a belt.

Rope Driving. For heavy drives cotton ropes are frequently preferred to belts. These are generally from 1 in. to 2 in. in diameter, and the pulleys are provided with grooved rims, each rope running in a separate groove. The sides of the grooves are inclined towards one another at an angle of about 45°, so as to grip the rope firmly, without allowing it to touch the bottom of the groove. The working tension is about the same as with leather belts—namely, 300 lb. per square inch (of the circumscribing circle), but the tension in the slack side is less than half that in the tight side, so that the power transmitted per square inch is greater. The usual speed is about 5,000 ft. per minute, and the diameter of the smaller pulley should not be less than 30 times the diameter of the rope. Assuming the ratio of the tensions in the two sides of the rope to be 5 : 1, and the speed in the neighbourhood of 5,000 ft. per minute, and allowing for centrifugal force, the following formula gives the horse-power transmitted by each rope:

$$\text{Horse-power transmitted: } HP = \frac{1}{1000} d^2DN,$$

where d = diameter of circumscribing circle of rope, in inches,
D = diameter of pulley, in inches,
N = number of revolutions of the *same* pulley per minute.

Thus a single rope may transmit as much as 75-horse power, and by placing 20 ropes side by side, 1,500-horse power may readily be dealt with, a power which would require an unwieldy leather belt if such were used. Ropes are more efficient than belts, but the latter have the advantage that they can be used to transmit power between shafts which are not parallel with one another, and can readily be taken off or moved from one pulley to another; this operation is frequently necessary in the case of the belts used to drive individual machines, the belt resting on an idle or "loose" pulley when the machine is at rest, and being transferred to the working or "fast" pulley when it is desired to use the machine. Hence, although ropes may be employed to drive the shafting in a mill or factory, belts are almost invariably used to take the power off the shafts for the machines.

Power Transmission by Gearing. Where a shaft is required to drive another at a different speed, the two being close together, toothed gearing is often used. In this case each shaft carries a wheel provided with teeth round its circumference, the teeth of one wheel engaging with those of the other and driving them. As the teeth on both wheels are equally

and shafts are in the inverse ratio of the numbers of teeth on the respective wheels, the smaller wheel running faster. The shape of the teeth is carefully designed so that they roll upon one another with the minimum of friction; they are either cast with the wheel, which may be of cast iron or steel, or are cut out of the solid rim when the best results are desired. Gear wheels are almost invariably noisy, however well they are fitted together; sometimes one of the wheels is made of raw hide to diminish the noise, or the teeth are made of helical shape for this purpose. Obviously, gear wheels cannot be used with advantage to transmit power over a distance exceeding a few feet, and in this respect they are inferior to belts and ropes. They are very useful, however, for driving shafts which form an angle with one another, the gear wheels, which are then called *bevel wheels*, being made of conical shape; they can also be used for fairly high speed ratios, and have the advantage of great compactness.

Worm Gears. For excessively high ratios, such as 30 : 1, worm gear is often This consists of a toothed wheel driven by a "worm," the latter being a single turn of a screw-thread, the pitch of which is equal to that of the teeth of the gear wheel; thus one revolution of the worm causes the wheel to advance one tooth. Owing to the sliding friction between the worm and the teeth, it is absolutely necessary that they shall be thoroughly well lubricated in order to reduce the loss of power, and for this reason worm gear should always be immersed in an oil bath. It is rarely used for transmitting large powers.

Chain Driving. Another positive driving device is the chain and sprocket-wheel, the most common illustration of which is the driving gear of bicycles; but the latter as ordinarily made is inferior to the Renold "silent" chain, which drives on the flanks of the teeth instead of against the roots, and automatically adapts itself to the teeth as wear takes place.

Friction Gearing. Omitting the teeth from the circumference of gear wheels, and pressing the two smooth wheels together, we obtain friction gearing; this is sometimes used for transmitting small powers, and has the advantage that it is noiseless, and will slip rather than break when overloaded. Preferably the gear consists of a wheel built of paper or leather discs compressed between two plates of iron, working against a cylindrical cast-iron pulley. Unfortunately, considerable pressure is thrown on the bearings by this gear, and oil accidentally dropped on it immediately causes slipping.

All the foregoing methods are available for use in works and machines, and their efficiencies are all of the same order—about 90 per cent.—but in the case of worm and chain gearing as ordinarily used, the efficiency may be much lower; in fact, 90 per cent. is attainable with these gears only under exceptionally favourable conditions.

Wire-rope Driving. When power is to be transmitted to a distance exceeding the limits of a factory, different methods must be used. The one which most nearly resembles those discussed above is that of driving by means of wire ropes, consisting of steel wires stranded together, spliced to form a continuous loop, as in cotton rope gearing, and passing over the driving and driven pulleys, each of which usually has only one groove. The distance between the driving and driven pulleys should not exceed 500 ft. If greater distances are to be covered, successive relays must be used, the first driven pulley becoming the driver for the second rope, and so on; in this case the intermediate pulleys have two grooves each. Sometimes guide pulleys are used to support the rope at intervals between the main pulleys. By means of ropes 1 in. in diameter, it is possible to transmit 300-horse power a distance of half a mile with an efficiency of nearly 90 per cent., the relays being five in number, and the rope running at 4,000 ft. per minute.

Electrical Power. When distances exceed 300 ft., however, it is far better to adopt one of the methods mentioned on a previous page —namely, electrical, pneumatic, or hydraulic transmission. Of these, electrical transmission is discussed in the course on Electricity. It will suffice here, therefore, to mention its advantages for power transmission. Of these, the most important are high efficiency; extreme flexibility, for the power can be transmitted to any distance desired, and used in any suitable manner, while in driving workshops the shafting may be divided up into sections of any length; individual machines may be driven separately; any part of the works may be run independently of the rest; the buildings need not be laid out to suit shafting, and need not be so substantial, and any machine may be run or stopped without interfering with any other, or requiring long shafts to be driven; light is available as well as power; energy can be stored in batteries as a reserve, or to steady the load on the generating plant, and thus economise coal; there are no moving belts, ropes, or shafts in the space between the driver and the machine driven; and not least, without dwelling on other additional advantages, with electricity it is possible to keep a close watch on the performance of every part of the plant, and at once to note any falling-off in its efficiency. For transmitting power from a central point to a number of independent consumers, electricity is unrivalled, its high efficiency and flexibility being unique for this purpose, and there is no limit to the amount of power that may be transmitted by a single line. Withal, it is now possible to supply electricity in many places at a price which competes favourably with that of any other power

Pneumatic Power. Pneumatic power transmission possesses many advantageous features, accompanied, however, with certain inherent disadvantages. The latter have rendered it unsuitable for distributing power on a large scale, or transmitting it over great distances, though before the development of electrical transmission it was widely used. In this system, air is compressed by steam or other power-generating plant to a high pressure, and is transmitted through pipes to the place where the power is required, and there passed through air motors or other machines giving out mechanical power. The great difficulties met with in utilising air in this way are due to the heating of the air during compression, and to the converse phenomenon—the cooling of the air during expansion. Each of these characteristics leads to a serious loss of power. The act of compressing air or any other gas is necessarily accompanied by the evolution of heat, by reason of the work done on the gas. If the air thus heated were at once supplied to the air motor, losing but little heat on the way, it would be cooled to a corresponding extent during expansion, and discharged at a temperature not much below that of the atmosphere, the loss due to heating being then inconsiderable.

Compressing the Air. The air is usually compressed by compound steam engines, and in order to reduce the loss of power due to heating the compressed air, the compression is divided into two stages, the air being partially compressed, then passed through a cooling apparatus, and again compressed. By this means the temperature at which the air leaves the compressor is reduced. On the other hand, the expansion of the air in the motor produces very low temperatures, causing the moisture in the air to be deposited in the form of snow and ice in the exhaust passages. This is remedied by heating the air before it enters the motor, with surprising results, for the output is enormously increased, and it may be taken that reheating in this way is practically indispensable to high efficiency in pneumatic power transmission. Under the best conditions, the efficiency may be as high as 80 per cent., apart from the loss in the transmission line, which will absorb about 5 per cent. of the power per mile; under bad conditions the efficiency may be as low as

SALAR JUNG LIBRARY

30 per cent. When the air pressure is very high, as in the case of torpedo charging, four-stage compressors are used, raising the pressure to 1,430 lb. per square inch. For ordinary purposes the pressure is from 40 lb. to 100 lb. per square inch, generally about 75 lb.

Uses of Compressed Air. Although compressed air can readily be used as above described in motors similar in principle to steam engines, giving continuous rotational motion to a shaft, it is far more generally employed in simple reciprocating apparatus, for driving which it is admirably adapted, though the efficiency is not more than 40 per cent., as it is not usually convenient to reheat the air in these cases. One of the most important uses of the system is the driving of rock drills in quarries, mines, and tunnels, and for coal-mining. The drill consists of a cylinder in which a piston oscillates, being controlled automatically by the compressed air, and carrying a drill which strikes rapid blows on the rock. The air exhausted from the drill helps to ventilate mine workings. The system has been applied to drilling and caulking iron and steel, riveting, pneumatic lifts for placing heavy work in position in lathes, etc., in many factories. In Paris, the Popp system of driving clocks pneumatically has worked well for many years. The clocks, which are merely dials, with hands worked pneumatically, are installed over a large portion of the city. Passenger and goods elevators are sometimes driven by pneumatic power, and parcels are blown through tubes to considerable distances, as in the underground telegraph system in Paris. One of the most common uses of compressed air is in the operation of the brakes of railway trains [see page 4696]. Air compressed to very high pressures—up to 4,000 lb. per square inch—can be stored in steel cylinders, and used to propel locomotives and motor-cars, the air being supplied through reducing valves, which lower the pressure to 150 lb. or less, to the cylinders of air motors. It will be observed, however, that the use of compressed air is due to questions of convenience, not efficiency or economy of power. An important consideration is the danger of explosion, due to the presence of oil or coal-dust in the air passages, which are ignited by the high temperature of the air.

Liquid Air. Liquid air—that is, air which has been cooled by expansion to a temperature so low (minus 192° C.) that it becomes liquid at atmospheric pressure — has been suggested as a possible means of power transmission, as it increases in volume 720 times in passing from the liquid to the gaseous condition This process, however, involves gain of heat from external sources, such as the atmosphere and the apparatus in which it is used, the whole of the work, in fact, being done by this absorbed heat. Whether doing work or not, the liquid is constantly boiling away, due to the inflow of heat, and provision must be made to prevent the pressure of the gas from rising to a dangerous degree. The efficiency of the system would be excessively low, and the danger not inconsiderable.

Hydraulic Power. For many purposes, water pumped through pipes under great pressure forms a most convenient means of transmitting power, this system possessing certain advantages peculiar to itself. The source of energy is generally a steam engine, driving pumps, and thus feeding water into the pipes at a pressure ranging from 50 lb. per square inch (as in town supply) to 1,120 lb., or half a ton, per square inch. In the former (low-pressure) case the water is pumped up into elevated reservoirs, whence it is drawn as required, the pressure depending simply on the height of the reservoir above the point where the water is used. In the latter (high-pressure) case, the system is provided with accumulators, in which a quantity of water is maintained under the full pressure by means of weights attached to a piston working in a cylinder in communication with the pipes. When the pump supply is in excess of the requirements of the moment, the surplus water flows into the accumulator, raising the piston, and when the demand is in excess of the supply, the loaded piston descends, forcing the water through the pipes, and thus assisting the pumps.

Advantages of Hydraulic Power. Facility of storage is one of the chief advantages of hydraulic power transmission, as it enables the engines to run almost constantly loaded, while maintaining a uniform pressure in the mains. Only small powers are supplied at low pressure, the height of the reservoirs not usually exceeding 100 ft. ; but in high pressure systems, such as those installed for public supply in London, Manchester and Glasgow, large powers are conveyed with small quantities of water. The losses in transmission through friction in the pipes may be estimated at 5 per cent. per mile. The power is converted into rotary motion by means of hydraulic engines, consisting of pistons working in cylinders, and controlled by valves acting on the water supply ; owing to the incompressible nature of water, such engines cannot be run at high speeds, and therefore multiplying gear is generally necessary. When the engine is direct acting, the efficiency is about 85 per cent. ; the use of gearing reduces the efficiency. In engineering works, bridge construction, shipbuilding, etc., hydraulic power is widely used, being unexcelled in convenience and speed for riveting, punching, shearing, and bending. The machines used are very efficient and simple, consisting of little more than pistons and cylinders. For compressing bales of cotton, hay, etc., hydraulic presses are most suitable. In dockyards, railway stations, warehouses, etc., hydraulic cranes are very common, handling the greatest weights, and hydraulic lifts are met with almost everywhere. Huge hydraulic forging presses have largely superseded steam hammers for forging heavy iron and steel shafts, etc., while small hydraulic jacks, worked with hand pumps, are the most convenient and powerful portable lifting devices known. It will be observed that slow and intermittent motions are the most suitable for operation by hydraulic power.

GLUE, STARCH, AND INK

Manufacture and Testing Glue and Gelatine. Varieties of Starches and their Manufacture. Writing, Printing, and Other Inks

Continued from page 6150

By CLAYTON BEADLE and HENRY P. STEVENS

GLUES AND ADHESIVES

We can trace back the use of glue as an adhesive to the times of the ancient Egyptians, who in the reign of Thotmes or Thutmosis were certainly acquainted with the art of *veneering*—that is to say, coating one piece of wood with a thin layer of a more valuable material. In the sculptures of Thebes a workman is represented engaged in this work, while another is spreading glue with a brush. The pot for the glue is there standing on the fire, and a piece of glue with its peculiar conchoidal (shell-like) fracture. This attests to the use of glue by the Egyptians 3,300 years ago (Lambert). Besides this, there are plenty of references to glue in the literature of the ancients and the Middle Ages.

What is Glue? Glue is an animal product obtained from quite an assortment of substances, such as skins and other tissues, cartilage, hides, bones, fish bladders, fish scales, and all sorts of refuse odds and ends by boiling them down with water and suitably purifying the liquor. On cooling, it sets to a stiff jelly, the consistency and colour of which will depend on the raw materials and the purity of the final product. Glues may be roughly divided into three classes—skin glues, bone glues, and fish glues. These will be dealt with in order.

Gelatine is another product of the same nature as glue, and may be defined as a very pure, almost colourless variety of glue in the manufacture of which every possible care has been taken. The distinction between glue and gelatine is not very well defined, and the terms are often applied somewhat promiscuously. The points in which glue and gelatine differ are enunciated by Rideal as follows:

"Gelatine is made in pale, nearly colourless, thin sheets, and is used for purposes in which absence of taste, odour, and colour, with firmness of jelly and easy solubility, are required.

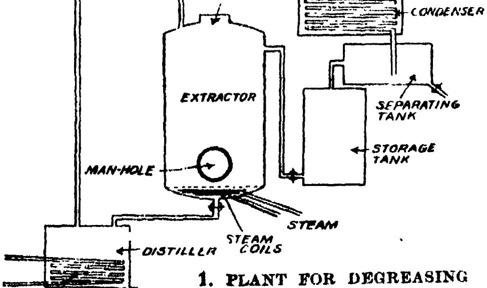
"Glue, on the other hand, is employed for its adhesiveness, stiffness, and elasticity, and is met with in the familiar thick and dark sheets."

The mode of manufacture of gelatine is, on the whole, similar to that of glue, and we shall therefore be content to indicate in the proper place, when describing the manufacture of glue, any differences in treatment or further precautions which it may be necessary to take.

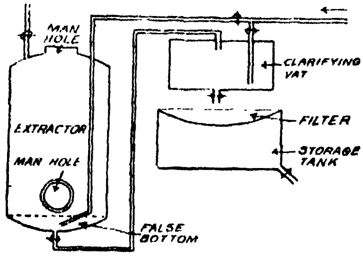
Skin Glue. This is obtained from the waste pieces of hide, etc., rejected by the tanner, who removes those portions which are unsuitable for conversion into leather, as, for instance, the heads and feet of calves and sheep, and waste, such as tail pieces of oxen, ears, clippings, etc. The hide of old animals is said to yield the best glue. The material, or "stock," is steeped in wooden vats, or cement-lined lime-pits, where the hides are exposed to the action of lime and water for two or three weeks, or longer, according to the class of material. A 2 per cent. milk of lime is used, and removes any fat adhering to the hide by saponifying it (converting it into a lime soap) It also swells the tissue, and helps to remove dirt and any blood or fleshy substance remaining attached to the hides. From time to time during the process the skins are raked about so as to expose fresh surfaces to the action of the lime. The cuticle, or outer skin, having been softened by this treatment, the hair can more readily be scraped off. After this, the hides must be thoroughly washed to remove every trace of lime, for which purpose it is not unusual to give them a preliminary souring with weak hydrochloric acid. This forms a soluble salt (calcium chloride) with the lime, which is easily washed out with water. The washers are provided with mechanical agitators, which keep the hides gently stirred until the operation is complete. The hides are then taken from the washers, pressed to remove excess of water, and hung up to dry.

New Inventions. In some works the use of lime has been given up, and a weak solution of soda is used instead, with this advantage—that the hides are much more easily washed free from alkali. The material is then treated with sulphurous acid solution in wooden vessels. This process, which we owe to Dr. Terne, loosens the skins so that on extraction the resulting liquors are clear and almost water white, and the glue or gelatine has an excellent appearance.

Where lime is still used, the souring with hydrochloric acid is likely to be replaced by a new process, devised by Francis T. Oakes (United States Patent 908,293), in which the hides, after washing with



1. PLANT FOR DEGREASING BONES



2. PLANT FOR GLUE EXTRACTION AND CLARIFICATION

water, are immersed in a bath containing 5 per cent. of glucose syrup and 1 per cent. of sulphur, reckoned on the weight of the skins or hides, with the further addition of 1 lb. of yeast for every 1,000 lb. of material treated. The bath is heated to a temperature of 95 to 100° F., and is allowed to stand twenty-four hours for fermentation to set in before immersing the hides. There is no need to keep the hides in constant motion; it suffices to stir them every hour or so to ensure uniformity of action; even heavy bull hides will be freed from lime and be left in a free and open condition at the end of eight hours. The process may be made continuous by removing half the liquor and adding further quantities of glucose, sulphur, and yeast after each lot of hides is removed, and before a new "pack" is added.

Extracting the Glue. The hides are now taken to the boiling vat, which consists simply of a large open vessel, with a coil of steam-pipes under a false bottom through which live steam can be forced into the vat. Under this treatment the mass of hides gradually sinks down, and the hot liquid dissolves out the glue. It must not, however, be supposed that the hides contain glue in the form in which we know it. The hot steam brings about chemical changes in the complex substances of which the hides are composed, liberating the glue, which dissolves in the liquor. As the material is gradually exhausted, fresh hides are added, and when the liquor is sufficiently concentrated (as shown by allowing a little to cool, and testing the firmness of the jelly), it is run off, strained through a sieve, and allowed to settle in vats for clarification. There are several chemicals which can be used to clear the solutions, but potash alum is usually found to work best. The liquors must be kept hot all the time by appropriate steam coils.

It remains only to concentrate the liquors sufficiently, which is most economically effected by treatment in some form of vacuum pan or multiple effect evaporating plant. [See Soda Recovery in Papermaking.] Before going further, we shall trace the production of glue from bones to the stage we have now reached in treating hides.

Bone Glue. Bones consist for the most part of mineral substances—phosphates and carbonates of lime and magnesia—in conjunction with certain organic constituents. These latter yield the glue liquor on extracting with hot water, but all bones as they reach the glue works also contain a certain amount of fat. The percentage both of fat and glue will vary with the age of the animal, as the bones of older animals contain a larger proportion of mineral matter. Thigh bones (marrows) yield more fat than heads, ribs, and shoulder-blades. On an average, the proportion of fat may be put at 17 per cent. to 18 per cent. in the former, and at 12 per cent. to 13 per cent. in the latter (Lambert). On the other hand, the long bones of limbs and vertebræ yield less glue. The organic matter other than fat from which the glue is derived will amount to 21 per cent. to 22 per cent. These figures refer to fresh bones, but those which have already been put to other use, such as soup-making, will yield much less of both fat and gelatine.

Degreasing Processes. Removing fat, or "degreasing" the bones, is the first operation, and used to be carried out by boiling in an open vessel and skimming off the fat. This method was subsequently improved upon by heating in a closed vessel under pressure (40 lb. to the square inch), and the yield of fat (bone grease), a product of considerable value to the soap-maker, was thereby increased from 5 per cent. to 7½ per cent., but at the same time a large proportion of the glue was extracted and obtained in admixture with the fat, necessitating subsequent separation. In the more modern methods the fat is removed by dissolving it out with a volatile organic solvent, such as benzene, whereby the bones are left in an unaltered state for glue extraction, and the fat can be obtained by evaporating off the solvent, which is then used over again in the next operation. The plant [1] consists of an upright boiler or extractor to take five tons of bones, which, after sorting and partial crushing, are introduced through a manhole in the top. Solvent is then run in. This usually consists of shale spirit or petroleum, boiling about 100° C., and free from the higher boiling constituents, so that it is completely volatile at temperatures attainable in the distilling apparatus—say, 135° C. Steam is now admitted to steam coils at the bottom of the extractor so that the hot solvent dissolves the fat; part of it, however, distils away through a pipe at the top, carrying with it moisture from the bones, and the vapours are led to a suitable condenser. As soon as the moisture has gone off, the solvent with the fat in solution is run off to the distiller, and a fresh quantity of solvent is admitted to the extractor. The distiller is provided with steam coils, so that the contents may be heated and the solvent driven over into the condenser. The process may be repeated three or four times, when practically all the fat will have been extracted. There remains to be recovered only a portion of the solvent still adhering to the bones, for which purpose live steam under 70 lb. or 80 lb. pressure is driven through the mass, carrying the solvent with it away to the condenser. Under the condenser is the separating tank, where the light solvent is drawn off from the aqueous liquor into the storage tank for use over again.

Cleansing Process. The degreased bones, which will not retain more than ·2 per cent. of fat, are removed from the extractor, and put through a slowly revolving drum built horizontally. The drum is made of stout wire gauze of wide mesh, and as the bones pass down, any pieces of foreign matter, dirt, etc., drop out, and are eliminated, while the purified degreased bones, containing 5 per cent. or 6 per cent. of nitrogen in a form removable as glue, pass on to the glue-boiling process.

3. GLUE TESTER

Boiling Process. This process is similar to that used in treating hides and is carried on in a large steel boiler [2] provided with a manhole at the top for introducing the raw material, and another at the bottom for withdrawing the exhausted material. As the extraction is carried out by live steam under pressure the boilers must be somewhat differently constructed from those used for treating hides. The live steam enters at the base and is distributed under a false bottom, on which the bones rest, and may be blown off from a pipe leaving the boiler at the top.

The pressure is allowed to rise to 15 lb., at which it is maintained for a couple of hours, when it is reduced to 5 lb. It is found that lowering the pressure causes the glue which has formed in the pieces of bone to come to the surface (Lambert). When the extraction is complete the bones are washed down with water from a sprinkler in the top of the boiler and the liquor is run off. The bones yield about 40 per cent. of their weight of glue as the result of double extraction; only a very small amount—about 4 per cent.—remains in the bones.

Clarification and Concentration of Liquors. As the glue-liquors leave the boiler they have a concentration of about 20 per cent., but they require to be further evaporated so that on cooling they solidify to a firm jelly of such consistency that it can be conveniently handled—that is, moulded, cut up, and dried. Previous to concentration, the liquors are heated with sulphate of alumina or alum in the same manner as the extract from hides were in the clarifying vat. About one half per cent. of alum is required, reckoned on the dry weight of the glue, and the liquors are heated to boiling for ten minutes by means of live steam. On standing, the heavy impurities settle to the bottom, and the lighter ones remain as a scum upon the surface and are removed by filtration through gauze of fine mesh or coarse calico.

If, however, the glue-liquors have been prepared from sound "stock" and properly cured, the first run of liquor comes away in a practically clear condition from the boilers. A large and relatively shallow vat is all that is necessary for clarification. The liquors are run into the vat and given sufficient time to allow the heavy impurities to settle out. The liquors from subsequent extractions are usually muddy, and instead of attempting to clarify them, it is the custom of some manufacturers to incorporate with them substances such as zinc white or barytes to produce the so-called "Russian glues."

In the preparation and concentration of glue-liquors, an apparatus [3 and 4] is much in use for ascertaining the percentage of glue in the liquors. This glue-tester [3] is a form of hydrometer [see PHYSICS], with a compensating thermometer made in one piece. To find the percentage of glue the instrument is immersed in the liquor and the reading taken at the point where the stem rises above the surface. The figure so obtained is corrected for temperature by a reading of the thermometer scale on the back of the stem and shown on somewhat magnified scale in 4. Thus, supposing the instrument sank to the mark 25 on the large scale, it would be necessary to subtract 7·7, thus 25 − 7·7 = 17·3, which gives the percentage of glue straight away.

4. GLUE-TESTER STEM
Upper Part

The concentration is best carried out in a double effect vacuum evaporator. (We cannot go into the working of this plant here, but it is described under Papermaking, where it is used for concentrating caustic liquors.) By this means our liquors will now have a dry glue content of 32 to 35 per cent., according to the time of year. As the consistency of the jelly is affected by the temperature a more concentrated liquor is required in summer than in winter.

Bleaching. The concentrated liquors are often bleached at this stage to improve the colour, but the product has not the qualities of a good class gelatine, where freedom from colour is due to careful selection of raw material and precautions which have been taken in the process of manufacture.

In any case, sulphurous acid is almost universally employed; more active bleaching agents are out of the question, as they would attack and destroy the glue.

Bleaching powder has been used in Germany, but the operation has to be most carefully watched and stopped at the right stage to prevent spoiling the glue. Residues of bleach remaining in the liquors necessitate the addition of an anti-chlor such as sodium sulphite. Sulphurous acid is made by burning sulphur in special furnaces [see Acids and Alkalies, pages 4625 and 4770]. The gas is passed through the glue-liquors contained in tanks kept hot by suitable steam coils.

Sulphurous Acid Process. In the manufacture of high-class glues and gelatines the bones may be treated with acid before extracting the glue. In the older processes for the manufacture of gelatine from bones they were immersed in hydrochloric acid a sufficient time to dissolve out the calcium phosphate and other mineral matter, and, after being thoroughly washed, were bleached by immersion in sulphurous acid liquor. The two operations are now frequently combined in one. The air-dry bones (English Patent 2175, 1894) are exposed to the action of sulphur dioxide for a long time in closed vessels until they have taken up some 10 to 12 per cent. of their weight of the gas. Bones that are too dry must first be moistened. The chemical reaction that ensues may be thus represented:

$$Ca_3(PO_4)_2 + SO_2 + H_2O = 2CaHPO_4 + CaSO_3$$

$Ca_3(PO_4)_2$	SO_2	H_2O	$2CaHPO_4$	$CaSO_3$
Insoluble bone material	Sulphur dioxide	Water	Acid calcium phosphate	Insoluble calcium sulphite as sediment

The calcium phosphate, which is soluble in weak acid, may be removed by leaching, leaving the glue mass intact. The bones, which have become brittle, are easily extracted, leaving the calcium sulphite as a sediment. The glue-liquors have an acid reaction, and are somewhat muddy. Treatment with lime, however, clears them and neutralises the acid.

This process is suited to bones which have not been degreased, as the fat separating from the glue-liquors rises clear from the hot liquor.

A modification of this method is worked in Germany. After treating with sulphur dioxide, the bones are sprinkled with water and re-treated under a pressure of 1½ to 2 atmospheres at the ordinary temperature in lead-lined digesters. The calcium sulphite is thereby converted into bisulphite.

$$Ca_3(PO_4)_2 + 4H_2O + 4SO_2 = CaH_4(PO_4)_2 + 2CaH_2(SO_3)_2$$

$Ca_3(PO_4)_2$	$4H_2O$	$4SO_2$	$CaH_4(PO_4)_2$	$2CaH_2(SO_3)_2$
Insoluble bone material	Water	Sulphur dioxide	Soluble calcium phosphate	Soluble calcium bisulphite

Thus, both this and the acid phosphate may be extracted with water leaving the pure glue mass behind.

When extracting gelatine, to preserve a good colour the temperature of the liquor should not be allowed to rise above 85° C. Some of the best gelatine is clarified with albumen, such as blood or white of egg, in the place of alum.

Moulding and Cutting. The clarified, concentrated, and bleached liquors are jellied by pouring into moulds or cooling-boxes, made of strong sheet zinc, so that large flat cakes are obtained five or six inches thick, or the liquor is run on to glass tables the surfaces of which are kept cool by a current of cold water underneath.

The blocks of jelly are cut into small slabs by wire cutting frames similar to those used in making wire-cut bricks or soap-slabbing machines. Either the block of jelly is put in a box, the sides of which are provided with a number of slots so that a wire fixed on a frame like a fretsaw may be passed down through the block and guided by the slots on each side, or else the block may be cut up into the correct number of slabs in one operation by forcing it against a frame across which wires are stretched at suitable intervals. In another machine the block of jelly is carried forward on an endless belt and sliced by a number of fixed wires which are set diagonally to the cutting plane, and therefore at some distance apart, so that one slice only is cut at a time. It is claimed that by this means a regular and uniform action is ensured with less strain on the wires, which consequently last longer.

5. KJEDAHL FLASK

In Hewitt's process a hollow steel cylinder revolves slowly, just dipping into a trough containing the glue-liquor. A current of cooled brine is drawn through the cylinder, and the flow of brine and the speed of the cylinder adjusted so that the layer of glue adhering to the surface of the cylinder solidifies in less than one revolution, and the firm jelly is wound off in the form of an endless ribbon, which then passes to an appropriate machine which cuts it into pieces of suitable size.

In some countries the rooms in which glue-liquors are solidified have to be cooled in the hot weather. This is best effected by pipes running along the ceiling and carrying cooled brine. [See Food Preservation.]

Drying. This is one of the most delicate operations in glue-making, and is subject to all sorts of difficulties. For some reason or another thunder in the air is said to exert an especially harmful influence, and to spoil whole batches of glue. No explanation has been offered beyond the suggestion that the effect is possibly due to the ozone produced in stormy weather.

The glue must not be dried too slowly, or the "bacillus subtilis," which has the power of liquefying glue, may get a foothold, and all sorts of other bacteria and moulds will develop.

From this it will be seen that the old-fashioned mode of drying glue in the open could be carried on only at certain times of the year, and in certain weathers, and even then with very uncertain results.

Modern Methods. At the present day glue is dried generally in tunnel dryers. The sheets of glue are placed on netting (preferably wire netting, as the cotton threads often used are a breeding ground for bacteria), and stretched on frames which are piled in stacks in a small waggon made to run on narrow rails through the tunnel. The tunnel may be six or eight feet broad and high and 250 ft. long; it is usually lagged to minimise the influence of the temperature of the surrounding air. A current of air is drawn through the tunnel, the temperature of which must be carefully regulated, as the melting point of the undried jelly will often not exceed 25° C. It will therefore be necessary in hot weather to cool the air in a refrigerator before allowing it to enter the tunnel, otherwise the glue will melt and tend to run through the nets. On the other hand, the drying must not be too rapid, or a tough film will be formed on the outside, offering a barrier to further drying of the interior, and preventing gradual and regular contraction of the mass. This skin imprisons numerous bubbles or air spaces, producing an unsightly appearance and diminishing the value of the finished glue.

As a further precaution against putrefaction, the air drawn through the tunnel dryers may be charged with small quantities of chlorine or sulphur dioxide gases.

Fish Glue. The purest form of fish glue, or "isinglass," is obtained from the floating bladders of various species of fish, especially the sturgeon. The bladders are cut up into strips and softened in hot water until the muscular outer coat can be stripped off. The residue is freed from fat, blood, and other impurities, and after drying in the air, forms the raw material for glue extraction. In addition to this, a considerable quantity of inferior strong-smelling glue is extracted from the "offal," which is first subjected to a preliminary washing and then extracted in digesters with live steam in a manner already described in the treatment of bones. It is obtained in the form of a light brown viscous liquid, with an offensive odour. Many of the liquid "fish glues" sold consist of ordinary bone or hide glue chemically treated so that it remains liquid even when in a concentrated state.

"Fibrin glue" is another form of animal glue obtained from blood, and there are various "artificial isinglass" or isinglass substitutes on the market which, according to Krüeger, are prepared from the intestines or bladders of sheep and goats.

Chemical Composition. Now that we have traced the manufacture of glue from different raw materials, let us look a little more closely into the chemical nature of the products. The trade draws a distinction between bone glue and hide glue, and there are certain chemical tests which help us to identify them. On burning a piece of glue a voluminous coal-like residue is obtained, which, on moistening from time to time with ammonium nitrate solution, and reheating, can be burnt away, leaving nothing but the mineral matter originally contained in the glue in the form of ash. The quantity obtained from a properly prepared glue or gelatine is very small, not exceeding two or three per cent. Bone glue yields a fusible ash of neutral reaction, consisting of the phosphates and chlorides of calcium and magnesium; these elements may therefore be detected in a solution of the residue by the ordinary chemical reactions [see Analytical Chemistry, page 4407]. The ash of hide glues does not fuse so easily, and consists of caustic lime, probably arising from lime used in the process of "liming" the skins.

6. KJEDAHL FLASKS ON STAND

But whatever its origin, glue is composed mainly of two nitrogenous substances, "glutin" and "chondrin," closely resembling one another in appearance and properties. In chemical composition, too, there is scarcely anything to distinguish them, both containing 50 per cent. of carbon and

6·6 to 6·7 per cent. of hydrogen. Glutin, however, contains more nitrogen, 18·5 per cent., as against 14·5 per cent. in chondrin, the remainder in both cases being oxygen. The adhesive properties are attributed to glutin and, although both glutin and chondrin form jellies, the latter forms the firmer of the two. If this be so, glutin should be the main constituent of a glue for adhesive purposes, and chondrin where high gelatinising power is required, as in the preparation of table jellies.

Small quantities of acids, alum, lead acetate, etc., precipitate chondrin from an aqueous solution, while solutions of glutin are not so precipitated.

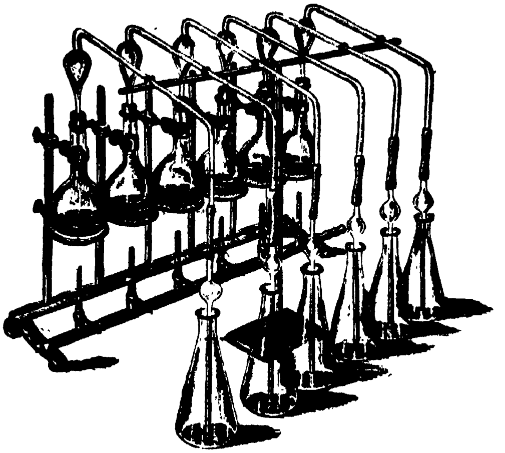
Chemical Reactions. One of the most characteristic reactions of a glue or gelatine solution is obtained on adding a little solution of tannic acid, whereby a white, flocculent precipitate of tannate of glutin is obtained, which is soluble in alkalies. On drying it forms a hard, brittle mass.

Attempts have been made to estimate glue by precipitating it with a tannin solution and weighing the precipitate, or by adding a known excess of tannin, filtering off the precipitate, and determining the tannin in the filtrate. The precipitate, when thoroughly washed with hot water and dried at 105° C., is said to contain approximately 42·7 per cent. of glutin. But the nitrogenous matters in glue consist of other substances besides glutin, and include chondrin, albuminoses, and peptones, some of which are of little or no value; indeed, peptones actually detract from the value of glue. All of these are precipitated with tannic acid, and would, therefore, be reckoned as glutin in an analysis made in the above manner. When it is further remembered that "over boiling" detracts from the value of a glue, and that "a solution allowed to cool and remelted has not the same tenacity as a freshly prepared solution" (Lambert), probably owing to the formation of peptones, the need for a test which will discriminate between glutin and the peptones formed by its decomposition is all the more evident. On the other hand, it is said to be a distinct advantage to use glue which has been dried down and dissolved up again for sizing paper.

8. LIPPOWITZ SHOT TEST FOR GLUE CONSISTENCY

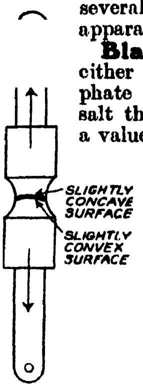
The determination of the percentage of nitrogen, best effected by Kjedahl's method, also fails to discriminate between glutin and other nitrogenous substances, although this test is of considerable value in estimating the percentage of glue in nonnitrogenous substances generally.

Kjedahl Estimation. Organic substances containing nitrogen (as albumens or proteids) are completely decomposed when digested with hot strong sulphuric acid. The nitrogen passes into the form of ammonia and remains, in combination with sulphuric acid, as ammonium sulphate. An accurately weighed quantity—say, one gramme or more—is placed in a flask [5] with a capacity of two or three hundred cubic centimetres and a measured quantity of strong sulphuric acid is added. The acid need be measured only roughly, and 10 or 20 c.c. will suffice. The flask is heated with a small flame and much sulphur dioxide gas is evolved. Fig. 6 illustrates the process of heating three such flasks. At this stage the contents may have a tendency to foam over and must be carefully watched. Then add 4 grammes (approximately) of sodium sulphate for every 10 c.c. of sulphuric acid taken, and heat up the flask, so that the contents just boil. The addition of sodium sulphate will allow a higher temperature to be reached than would otherwise be the case, and the reaction being more energetic proceeds faster. The charred mass gradually changes to dark brown, then yellow, and finally colourless liquid in the course of two or three hours. After cooling, dilute with water and distil off the ammonia with caustic soda, collecting in an excess of standard acid. This method is very extensively used, for instance, by the physiological chemists and all who require to analyse organic products containing nitrogen, such as gelatine, glue, etc. Thus it may be applied to determine the amount of gelatine in (tub-sized) paper or the percentage of albuminoids in cattle food, etc. [see Cattle Foods]. It is often necessary to make several analyses at the same time, when the apparatus shown in 7 will be found suitable.



7. KJEDAHL DISTILLATION APPARATUS

Blank Determinations. Should either the sulphuric acid or sodium sulphate happen to contain any ammonium salt the calculated result will give too high a value, as this and any other nitrogenous matter will be reckoned as contained in the substance analysed. It is usual to make a "blank" estimation, which is carried out in exactly the same manner as the foregoing, using the same quantities of reagents, heating the same length of time, etc., but without adding any of the substance to be tested. If the titration shows that some of the standard acid in the flask has been neutralised, the calculated amount of nitrogen must be deducted from the total nitrogen found. Should the blank experiment show a considerable percentage of ammonia distilled over, there is something seriously wrong. Either some alkali has been carried over or the reagents are impure, and the analyses must be repeated.



9. KISSLING'S GLUE TESTING APPARATUS

Zinc Sulphate Method. Trotman and Hackford recently claim to have solved the problem "and to have shown that good and bad glues may be chemically differentiated by means of the ratio between total nitrogen and nitrogen in substances precipitated by zinc sulphate, and that any carelessness in manufacture which increases the quantity of nitrogen incapable of such precipitation decreases to a corresponding extent the value of the finished glue." The method is carried out as follows: One gramme of finely powdered glue is dissolved in not more than 20 c.c. of water. To the hot solution crystals of zinc sulphate are added in excess to saturate the liquid. It is then well stirred with a glass rod and filtered through a funnel containing a plug of glass-wool forced into the stem and washed with saturated zinc sulphate solution. The glass-wool and precipitate are then introduced into a Kjedahl flask and the nitrogen is estimated in the usual manner.

Glue is best dissolved by first allowing it to stand overnight in cold water, which causes it to swell greatly, and then pouring off the water and dissolving in a fresh quantity of hot water. The gluepot should not be heated over a free fire, as lumps of partially dissolved material may stick to the bottom, and char, but the vessel containing the glue should be placed inside a larger vessel containing the hot water. Prolonged heating injures the glue, detracting from its consistency, and increasing the tendency to foaming, both effects, according to Trotman and Hackford, being due to formation of peptones. A glue which foams badly is of little use in making joints, especially when applied by means of a rotary brush, as the air-bubbles spoil the joint; in dressing fabrics a glue of this sort produces an uneven deposit. To test the tendency of a glue to foam, 25 c.c. of a 10 per cent. solution is poured into a graduated tube 70 cm. long, having a capacity of 70 c.c., and warmed in a water bath to 60° C. The tube is then corked and vigorously shaken. The height of the foam, termed the "foam figure," is read off, and on comparing a number of samples in this manner their relative value may be ascertained.

Consistency. It should be remembered that most glue tests are only relative, and to obtain results of value one sample must be taken as a standard by which to compare the others. This consideration applies to tests of consistency or strength of a glue jelly. Equal quantities of the glue samples are weighed out, and 10 per cent. jellies prepared. It is as well to weight the swollen glue that has stood in water overnight. As a general rule the better the glue the more water it takes up. The consistency of the 10 per cent. jellies may be compared by pressing them gently with the finger tips. Notwithstanding the "personal equation," different persons will usually grade the jellies in the same order.

Lippowitz applies the test in a different manner. Five parts of glue are dissolved in 45 parts of water, and the liquid poured into a cylinder [8], allowed to cool, and to stand twelve hours. A cup is fixed to a metal rod provided at the lower end with a button shaped like a bolt head, which rests on the top of the jelly, and the rod passes through a guide fixed to the top of the cylinder. Shot is poured into the cup until the bottom end of the rod ruptures the surface of the jelly.

Tenacity. No satisfactory method has yet been devised for testing the tenacity of glues. Weidenbusch works up powdered gypsum with a 10 per cent. solution slightly warmed, and moulds it into narrow rods. A rod is tested by laying it across a metal ring, and pouring mercury into a cup suspended from the middle of the rod. The weight of mercury required to break the rod is a measure of the adhesive properties of the glue.

Other experimenters glue together the surfaces of wood or metal and determine the force required to wrench them apart. The disadvantage of using wood lies in the fact that the wood itself at times gives way instead of the glued surfaces. Kissling uses nickel-plated iron [9], but objections have been raised to the use of a smooth metallic surface for testing glue intended for applying to the uneven surface of a piece of wood. From the papermaker's point of view its strength-giving qualities should be determined in the manner described for gum arabic.

Glue and Gelatine. We have enumerated some of the principal tests for glues, let us now compare the results of tests made on a fine brand of gelatine and on an average sample of dark Scotch glue. It was found that the tenacity of the Scotch glue was rather greater than that of the gelatine. On preparing 5 per cent. jellies of each the consistency of the gelatine jelly was 10 times as great as that of the glue in cold weather, while in warm summer weather the glue was liquid while the gelatine was still a stiff jelly. In some cases it is of interest to compare the viscosity of glue solutions. In the case we are considering the viscosity of a 5 per cent. gelatine solution was twice that of the corresponding glue liquor.

Uses of Glue. In the first place glue is extensively used by woodworkers and cabinetmakers, for veneering woods and other purposes. It is also used as an agglutinant in the manufacture of matches, to attach the mineral composition which forms the head of the match. The textile trades use large quantities of the best grades for dressing and finishing fabrics, and also for mixing with the colouring matter in calico printing. In combination with glycerin, gelatine is used in multiple copying presses, and, with chromium salts, in the manufacture of printing-rolls. It is also used for coating photographic plates, and for "tub sizing" and coating paper. Gelatine is extensively employed in culinary work, and in the confectionery trade. Although recent research seems to show that its nutritive value is probably slight, jellies for table use will no doubt continue to find favour.

The adhesive properties are very great, and various forms of liquid glue, usually in collapsible metal tubes, are in general use as a substitute for the glue-pot. Fig. 10 shows a piece of glue in which a small quantity of glue jelly has been allowed to dry down. So firmly has it adhered in places to the surface of the glass that on contracting it has torn little pieces bodily away, producing a peculiar fern-like pattern. The destruction of glass and porcelain vessels in which glue or gelatine has been inadvertently allowed to dry down is only too familiar to the student.

Casein Cements. The substance known as *casein*, which is now manufactured in considerable quantities from milk after separating the fat, has been recently applied for a number of purposes, among others for the production of adhesive cements. An ordinary solution of casein resembles in many respects a glue solution, and is prepared by dissolving casein at a temperature not higher than 60° or 70° C., with the aid of a small quantity of ammonia or carbonate of soda, preferably the former, as the ammonia gradually evaporates, leaving only the casein behind.

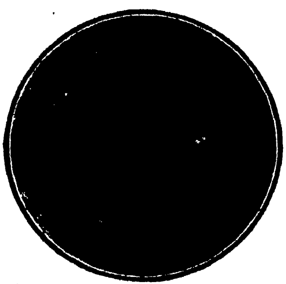
Another method of dissolving casein is to mix 150 parts with 75 parts of sodium tungstate. It is then gently warmed, stirred, and poured into moulds. The product can be used like glue by dissolving in water, or a solution in water may be prepared for use.

For many purposes casein is first softened in lime water, and is then treated with further quantities of lime and water glass (German patent 116,355) as follows: 12½ parts of ground casein powder is mixed with three times the quantity of clear lime water, and allowed to stand for 48 hours. The mass of swollen casein is further treated with 2½ parts of lime, and 25 parts of water, and vigorously stirred for 20 minutes. The mixture is further treated with 17½ parts of water glass, and again thoroughly mixed. After standing for some time the mass is further diluted.

Besides alkalies and ammonia, a number of other substances may be used for dissolving casein and preparing a liquid glue, such as borax, sodium phosphate, sodium tungstate, and sodium silicate. This last is said to yield the best cement for porcelain, although cements for almost every purpose can be prepared by suitable choice of solvent. [For uses of casein as distemper see PAINTS AND POLISHES.]

Adhesives of Vegetable Origin. These usually belong to one of two classes. In the first class we may place gum arabic. In the second starch, dextrin, etc. [see below].

Gum arabic is an exudation from the bark of certain varieties of acacia trees, and never comes from Arabia, as its name might lead one to infer, but from parts of Africa, particularly the North-east, West, and South. That coming from the North-east is generally regarded as the highest quality. Senegal and the Cape yield similar gums. A new source of supply has recently been discovered in Central Asia, in the districts traversed by the Bagdad Railway.



10. GLUE DRIED ON A PIECE OF GLASS

Some of the gums do not dissolve in water, but form a thick, slimy mass, and are used for thickening polishes, etc. The true gum arabic is soluble in water, and gives a solution which reacts weakly acid to litmus. This acid reaction, however, is not brought about by the gum itself, but by traces of sulphurous acid used for bleaching and purifying it.

The gums are usually found in conjunction with small quantities of mineral bodies, sugars, tannin, colouring matters, etc., and to prepare the pure substance they are dissolved in water and the solution *dialysed*—that is, placed in a circular tray like a drum-head, with a parchment bottom. This tray is floated on a pan of water. Most of the impurities pass through the membrane, leaving the solution of pure gum behind, which can be further purified by precipitating with alcohol. Very little is known as to the chemistry of the pure gum, whether it is a single substance or a mixture of substances, although the latter view is the more probable. When boiled with dilute sulphuric acid a peculiar five carbon sugar known as *arabinose* is produced.

Characteristics and Adulterants. The varieties of gum arabic which are found on the market are characterised by their strength, colour, and solubility, as well as by the country from which they are imported. Good varieties dissolve completely in their own weight of water, and as easily in cold water as in hot.

Solutions of gum arabic react in a peculiar manner with starch paste, and convert the latter into dextrin. The two, therefore, cannot be combined in the preparation of adhesive substances.

In appearance, gum arabic consists of rounded or long-shaped lumps, varying in colour, odourless, and with only a very faint sweetish taste. The outer surface is often scarred and cracked. Gum arabic is frequently adulterated, especially as the better sorts are not easily obtained. It should be carefully examined, and appropriate tests applied according to the purpose for which it is required. Dextrin is a common adulterant, and may be detected by the following test, depending upon the fact that the solution of gum is precipitated in its gelatinised state by ferric chloride. A sample is dissolved in two parts of water and a few drops of concentrated solution of ferric chloride added. The solution gelatinises, owing to the presence of "arabin." Should, however, the sample be adulterated with dextrin, a whitish precipitate is formed on shaking with water. When only the pure gum is present, the gelatinous precipitate remains unchanged. Dextrin may also be detected by testing with Fehling solution, as commercial samples always contain sugar.

Gum arabic gives characteristic colours when treated with acid solutions of certain phenols, which are useful for purposes of identification. To separate a mixture of gum arabic and gelatine or glue, the property of tannin to precipitate the latter substances may be made use of, the gum arabic remaining in solution, which may be filtered off from the precipitate.

Adhesive Power. To test the adhesive property of gum arabic, strips of paper are saturated with a weak solution, and after drying, their strength is tested in a paper-testing paparatus. [See Paper Testing.] It will be found that the paper, after soaking in the gum, has become much stronger, at times twice as strong as the untreated paper. To arrive at a figure for the adhesive quality, the strength of the untreated strip is subtracted from that of the treated. The weight of gum taken up by the paper is also determined by weighing the paper before and after treatment. Imagine this weight of gum spread over a surface equal to that of the strip of paper, a figure for the strength may then be calculated on the unit sectional area.

As an adhesive, gum arabic is used for paper almost entirely, especially for stamps, envelopes, labels, etc., although mixtures of other and cheaper substances are often used for the same purpose.

For coating paper, a solution of 19 to 21 Bé. is strong enough. Such a solution is easily applied, and gives a coat having the necessary adhesive quality.

It is of importance that not more gum than necessary should be laid on to the surface of paper. Thus, according to Dr. Krüeger, the stamps of the Swiss Government are too heavily laden with gum. When fixed on to an envelope they are easily shifted before the gum has dried hard. The addition of borax as a thickener to solutions of gum arabic is recommended, and sulphate of alumina or calcium nitrate may also be used. They prevent the solution of gum penetrating too far into paper.

STARCH

Starch is an organic substance belonging to a class of bodies termed *carbohydrates*, and is composed of carbon, hydrogen, and oxygen in the proportions represented by the formula, $C_6H_{10}O_5$. It is very widely diffused in the vegetable kingdom, being an invariable constituent of plants, occurring especially in the seeds of the cereals and in roots and tubers, such as the potato. For manufacturing purposes, a plant is chosen which is easily cultivated besides containing a large proportion of starch, different raw materials being treated in different countries, according to climatic and other conditions. In England, rice starch, made from imported material, is the chief product, and is usually preferred for laundry work. In Germany, large quantities of potatoes are grown especially for the purpose of making starch, and although the ordinary edible potato contains some 13 per cent., the cultivation has made such progress that the average percentage has been raised to 20 per cent. and even more. Although some potatoes are used in the United States, they are not cultivated specially for the purpose, the main raw material consisting of maize or Indian corn. In 1904 some 110,290 tons were manufactured from this substance [see "Census Bulletin"], and as maize contains a fair proportion of proteid bodies (especially in the germ) as well as oil, it is sufficient to remove the greater part of the starch, leaving a residue containing the remainder of the starch, together with the proteids for use as cattle-food. Potato starch fetches a higher price than maize starch, as it is preferred for some manufacturing operations, especially in the textile industries.

Many other plants are worked up for the production of foodstuffs, such as cassava, arrowroot, etc. Much of the starch manufactured is converted into glucose for British gum, syrups, etc., and, in addition to the large quantities used in laundry work, it is also applied for sizing paper and cotton goods, dressing cloth, calico printing, etc.

Manufacture. The processes vary considerably, according to whether the raw material be rice, potato, or maize. Potatoes are first cleansed by steeping and washing in cylinders with special contrivances to remove stones. They are then reduced to pulp in special contrivances, provided with rapidly-revolving arms. In order to break up the cells and liberate the starch as completely as possible, a machine, known as a *rasper*, is frequently employed. The potatoes pass into a hollow cylinder provided with saw-blades on the inner surface. The cylinder is also fitted with a rapidly revolving shaft, carrying fork-shaped scoops, which pick up the potatoes and press them against the saw-blades, while water driven through the cylinder carries away the pulp with it. This pulp consists of starch granules, with a certain proportion of fibre, and the latter is separated by running the pulp through cylindrical wire gauze sieves of different mesh, so as to retain the coarser particles, while the starch granules suspended in water (starch milk) collect in large vats, where further separation of sand and heavy impurities is effected by stirring up and running off the starch milk. The liquors pass to settling vats or inclined planes, where most of the water is removed, the remainder being separated by filtration or by the aid of the centrifuge.

Rice Starch. Rice contains as much as 80 per cent. of starch, but its separation is difficult, as it is intimately bound up with the gluten. It is necessary to have resource to a chemical treatment. The rice is macerated for twenty-four hours with weak caustic alkali, 200 gr. to the gallon, and, after running off the alkali, is well washed. It is then ground in suitable machinery, and the flour passed through sieves, the coarser particles being returned to the mill for further reduction. The flour is then subjected to a second alkaline treatment, under the same conditions as before, and finally separated from impurities by subsidence and passage through silk sieves.

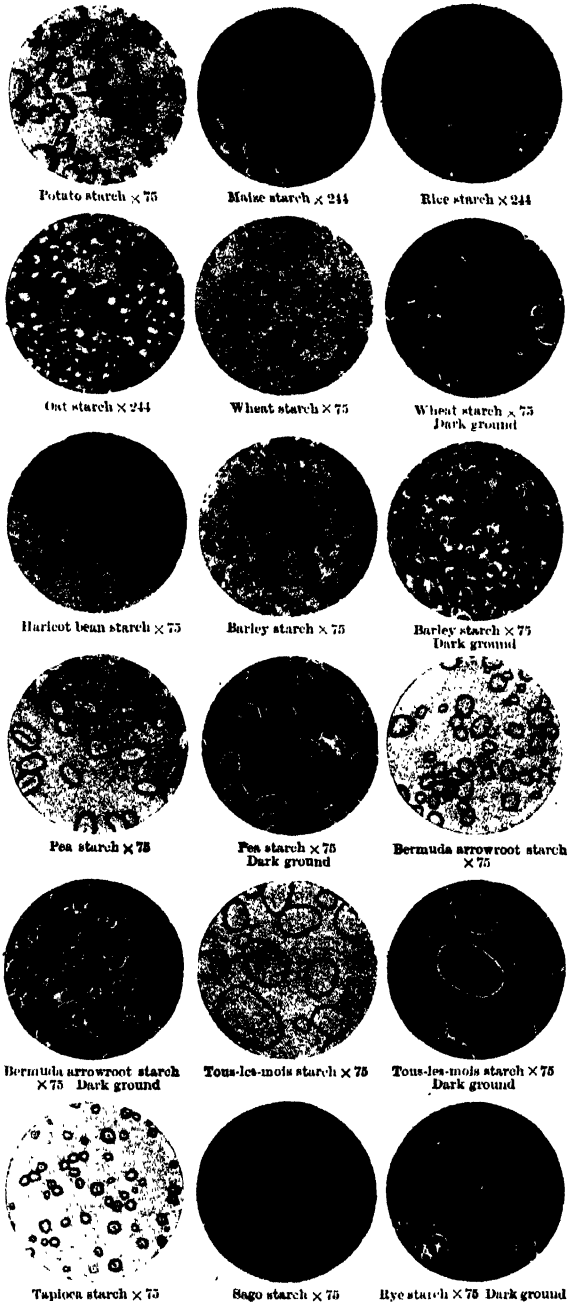
Wheat Starch. The whole corn is first steeped in water till soft, then crushed, and the liquor allowed to ferment. The action of the ferment is similar to the alkali used in the preparation of rice starch. Wheat was formerly much used for preparing starch, but for manufacturing purposes it has been replaced by cheaper substitutes.

Maize Starch. The manufacture of maize starch is very complicated, as the by-products consisting of the gluten germ and oil serve for cattle foods and other purposes. The process consists in steeping, followed by rolling and threshing, much of the starch liquor being separated at this stage by means of rubber-rolled wringers called "slop machines." The remaining semi-dry mass is treated in "germ separators," somewhat on the lines of a washer and stoner [see Milling, page 3078]. In the starch liquor, 8·5° Bé., the shells sink while the germ floats and is separated, the oil expressed, and the cake used for cattle foods. The plant used is described in that section. The starch liquors are run through metal gauze sieves, called "shakers," to remove germs, and the starch is separated in cone settlers or on starch tables. The dried starch, containing now some 10 per cent. of moisture, is ground in roller mills and passed through silk bolting machines.

Glucose. Strong starch liquors, 24° Bé., are pumped into copper cylinders or "converters," where they are heated with 1 per cent. of concentrated hydrochloric acid for twelve minutes at 35 lb. pressure. The starch liquors, now converted into glucose, are almost neutralised with soda ash, and the coagulated gluten, etc., allowed to settle out. The clear liquors are filtered through bone-black to decolorise them, and concentrated in vacuum pans. Glucose is much used in the manufacture of beer, aerated waters, syrups, and jams.

Starch Granules. The general appearance of starch is familiar to most people. The fine white powder is tasteless, odourless, and has a harsh feel when rubbed between the fingers. It is insoluble in water and unaffected by ordinary atmospheric conditions. When, however, a few grains are put under the microscope they are seen to have a very definite and characteristic structure, presenting the appearance of rounded or angular cells of varying shape and size, according to their origin. These granules consist of little sacks of inert starch, cellulose protecting the more reactive "granulose" or pure starch matter within. In the preceding sections [see Acids and Alkalies, pages 4625 and 4770] mention has been made of starch paste, which gives a characteristic blue colour, with even traces of iodine, but very little reaction is obtained with raw starch granules, as they are protected by the outer skin of cellulose. It is necessary to rupture this skin in order to free the granulose, which is easily effected by treatment with boiling water. The granules swell up and ultimately burst, so that on allowing the liquid to stand, the empty skins sink to the bottom, leaving a clear solution of the granulose above. The different starches vary in the ease with which they gelatinise, some starch granules bursting at a lower temperature than others. According to Lintner, potato starch is the most sensitive to heat, gelatinising at 65° C. Maize starch comes next at 75°, and the others at 80° or 85° C. These data account for some of the differences observed in the industrial applications of starch. The properties of the paste or solution of granulose varies a good deal, not only with the nature of the starch, but with individual specimens.

Microscopical Examination. As stated above, starch granules from different sources vary in appearance, and supply a means of identifying and distinguishing between the different varieties. The illustrations [**11**], which are reproductions of actual photomicrographs taken by Mr. Galt, will make this clear. For full detailed information the student is referred to his work on the "Microscopy of the More Commonly Occurring Starches," published by Baillière, Tindall & Cox, to whom we are indebted for permission to reproduce these illustrations. The photomicrographs are taken either by transmitted light, or on a dark ground. The translucency and general appearance are best shown by the former method, the outline and general shape of the granules by the latter. The magnifications are either 75 or 244 times the natural size, as will be seen from the subjoined list. The granulose in the interior is built up in layers, and some of the granules of potato and arrowroot show concentric markings which, although faint, are very characteristic. In addition, most starches possess a "hilum," or mark in the form of a spot or cross, the appearance and position of which is characteristic for each particular starch, thus the hilum of pea starch is slit shaped, in maize stellate, in Bermuda arrowroot near the broad end, and so on. The starch grains vary greatly in shape; potato starch forms flattened ellipsoids—that is to say, like an egg somewhat flattened — while maize is polygonal in outline and almost flat. Wheat starch is lenticular — that is, disc-shaped — but thick in the middle and thinning away down to the edges. The size of the grains also varies considerably, as will be evident on comparing the photomicrographs and the magnification. Tous-les-mois, a variety of arrowroot, has the largest grains, while those of oat and rice are very small; the average diameter of the latter may be taken as $\frac{1}{250}$th mm.



Potato starch × 75
Maize starch × 244
Rice starch × 244
Oat starch × 244
Wheat starch × 75
Wheat starch × 75 Dark ground
Haricot bean starch × 75
Barley starch × 75
Barley starch × 75 Dark ground
Pea starch × 75
Pea starch × 75 Dark ground
Bermuda arrowroot starch × 75
Bermuda arrowroot starch × 75 Dark ground
Tous-les-mois starch × 75
Tous-les-mois starch × 75 Dark ground
Tapioca starch × 75
Sago starch × 75
Rye starch × 75 Dark ground

11. PHOTOMICROGRAPHS OF STARCH (Galt)

INKS

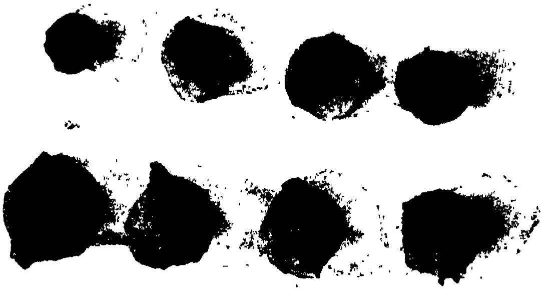
The use of inks dates from the times of the earlier civilisations, such as that of the Egyptians, and the ink on some papyrus documents is as black to-day as ever it was. The Chinese, too, invented ink centuries before Christ, but it was probably in the third century of our era that the so-called Indian ink—more correctly Chinese or Japanese ink—was introduced.

Pigments for Ink. Inks may be classed according to their nature and mode of manufacture and use. In the first place it is convenient to distinguish writing ink from printing ink, in addition to which there are miscellaneous inks, such as marking inks, copying inks, typewriting inks, sympathetic inks, stylographic inks, and many others. In the writing inks, the colouring matter or pigment is suspended or dissolved in an aqueous liquor, while the printing inks are prepared from colour ground up with oil and lithographic varnish.

Almost any colouring matter or pigment may be used in the manufacture of ink, but only some of them are really suitable for the purpose, and the object for which the ink is intended must also be considered. By far the great majority of inks used are black, or almost so, and with these there can be no question as to what should guide us in our choice of pigments. For documents and permanent records the writing or printed matter must be permanent, and must not fade when exposed to the light and air. This at once excludes most colouring matters and the coal-tar dyes, which are not sufficiently permanent for our purpose.

For printing inks, lampblack or finely-powdered carbon is the material almost universally employed, and it is also the basis of Indian ink. In the former case, the vehicle used is oil and varnish; in the latter a little glue and water.

Chemistry of Writing Ink. Writing inks, on the other hand, depend on the formation of tannate of iron in the paper. The permanent colouring matter is not contained in the ink as used, but gradually develops as the writing dries on the surface of the paper. At first glance this rather curious statement seems open to question, as we are familiar with inks with black or blue-black colour already developed. A short excursion into the realms of chemistry will be necessary to make this matter clear.



12. ALEPPO (TURKEY) GALLS

Writing inks may be prepared by mixing solutions of ferrous sulphate (copperas) with tannic acid. The former dissolves in water to a very pale green fluid; the latter, if pure, yields an almost colourless solution. Let us imagine for the time being that we are working with chemically pure substances. On mixing solutions of the two ingredients together, an almost colourless solution is produced which will contain ferrous iron in combination with tannic acid (ferrous tannate). Exposed to the air, however, it soon begins to darken and deposit a black substance; it gets thick, and as an ink would soon be of no use at all. The ferrous iron from the copperas is rapidly oxidised to ferric iron [see CHEMISTRY], and the black insoluble deposit formed is ferric iron in combination with tannin (ferric tannate). If previous to mixing the solutions of ferrous sulphate and tannic acid a little sulphuric acid be added to the former, the oxidation of the ferrous tannate is hindered, and the mixture will keep for a long time comparatively clear from deposit. The amount of sulphuric acid added need be only very small. When notepaper is written on with this ink, the acid is neutralised by minerals or other basic constituents in the paper, and is so weakened that it is no longer capable of hindering the oxidation of the ferrous tannate, and the black insoluble matter is deposited in the course of a few hours. Note, too, that it is deposited not only *on*, but *in* the paper, as the wet ink has time to soak in some distance before the oxidation process is complete. It would, however, be extremely inconvenient to write with colourless or almost colourless liquid; hence in the technical manufacture of inks an addition of indigo, aniline dye or logwood extract as a "provisional" colouring matter is made, which, with certain natural colouring matters contained in commercial tannin extracts, gives to the ink the colour we are accustomed to see. This colour is not permanent, but gradually fades on exposure to light and air, but the black iron tannate deposited in the paper is remarkably permanent. Its formation may be noted by comparing the colour of writing in blue-black ink just drying with what has been written the day before; the latter is much the blacker.

Tannins. Tannin or tannic acid is a substance widely distributed in nature and contained in the extracts from a number of plants. Some tannins are not suitable for ink-making. These are the "iron greening" tannins, such as are derived from hemlock, pine, kino, catechu, etc., which all give a green precipitate with iron salts. On the other hand, the "iron bluing" tannins, which give a blue precipitate with iron salts, and also as a general rule with potassium chromate, can all be used for making ink. These two classes of tannins probably differ from one another in chemical constitution, as on heating to 160° C the "iron greening" tannins yield catechol and the "iron bluing" pyrogallol; on these reactions is based a chemical test for distinguishing between them.

Raw Materials. Black inks—that is to say, inks which dry black—may be prepared from extracts of any vegetable substance, such as myrobalans, sumach, valonia or divi-divi, which contain iron bluing tannins; but the common materials are galls, and the particular tannin they contain is known as *gallo-tannic* acid. When acted upon by weak acids or certain moulds, gallotannic acid is converted into gallic acid, a chemically simpler substance, which goes further in making the same amount of ink. It is, therefore, used in the manufacture of the so-called gallic acid inks. Galls reach this country from the Syrian coast, and are commonly known as Turkey or Aleppo galls [12]. The female insect or gall wasp pierces the gall after a time, and escapes. Such galls show small holes, and are known as *white galls*. They contain less tannin than the unpierced galls, and consequently are worth less. A good sample of Aleppo galls will contain 60 per cent. or more of tannin.

The common English oakapple gall contains much less—16 to 20 per cent. tannin.

Chinese galls [13] are largely used on the Continent. They are produced by the Chinese aphis, and collected before the insect escapes, and contain 75 per cent. to 80 per cent. of gallotannic acid. Similar to the Chinese is the Japanese gall, which, however, contains less tannin. The chemist has several methods of measuring the amount of tannin in these products, and is therefore able to form a reliable estimate of the value of any particular material for ink-making.

Formulas for Ink. For every part of ferrous sulphate an infusion of about three parts of galls has been found to produce the best effect. There are innumerable recipes, dating from the time of Elizabeth. We will cite one or two.

Galls (1 lb.) extracted twice with 3 pints of boiling water, and the extract (2 quarts) mixed with 3½ oz. ferrous sulphate, and the same quantity of gum (Reid).

To prepare gallic acid ink, expose a decoction of 1 lb. galls to the air for 10 days, with continual daily shaking, and then add to each quart of the liquid 3½ pints of water, 9 oz. of ferrous sulphate, and 9 oz. of gum (Reid). Small quantities of "provisional colours," such as indigo or logwood extract, may be added.

The following is a standard ink of great permanency, the official standard record ink of the Commonwealth of Massachusetts, U.S.A., designed for use on State records. It is based on the formula of Schluttig and Neumann. We strongly urge its adoption in this country for similar purposes.

Tannic acid	23·4	parts
Gallic acid	7·7	"
Ferrous sulphate	30·0	
Gum Arabic	10·0	
"Dilute" hydrochloric acid	25·0	
Phenol	1·0	"

Each of the ingredients of quality prescribed by U.S.A. Pharmacopœia. Make up to 1,000 parts with water at 60° F.

What is Good Writing Ink? The following requirements are given by Mitchell and Hepworth:

1. It must yield permanent writing, which becomes black within the course of a few days.

13. CHINESE GALLS

2. It must flow readily from the pen and penetrate well into the fibres of the paper without passing right through the paper.
3. It must not gelatinise or become mouldy in the ink-pots.
4. It should have a minimum corrosive action on steel pens.
5. The writing must not be sticky.

The permanence of the writing is determined by exposure to bright sunlight for some time, a comparative test being made with a piece of the same writing kept in the dark. The effect of chemicals may also be tried. In testing the penetrating power it is, of course, necessary to use a standard paper. The extent to which different papers are sized varies enormously.

Inks are conveniently contrasted with a standard, for which purpose the standard ink may be taken whose composition has already been given.

Printing Inks. These consist of lampblack or other finely powdered pigment, incorporated with boiled oil or varnish. In the preparation of these latter, linseed oil is heated in a cauldron, and kept stirred. This causes the oil to thicken gradually, so that it can be drawn out into strings. The older makers heated the oil till it was on the point of taking fire; the source of heat was then removed, and the oil set fire to and kept continually stirred, the flame being extinguished by a cover, and the oil tested from time to time until the desired consistency was obtained. Savage prepared six quarts of "burnt" oil in this manner, and then stirred in 6 lb. of resin and 1¾ lb. of soap. The varnish, while still hot, was incorporated with the pigment, consisting of Prussian blue and lampblack. The preparation of burnt oil was an operation requiring the greatest care. Nowadays, the oil is not ignited, but air may be blown in, and certain chemical substances known as "dryers" are added, which facilitate the thickening of the oil. The operation is also carried out at a lower temperature than would be necessary without dryers [see also PAINTS AND POLISHES, page 5041].

As to the black pigments, all varieties of carbon blacks are used, according to the quality of the ink. For a description of the different pigments and machines for incorporation and grinding, see Paints and Polishes; also a carbon black obtained from coal-tar, which is described in that section.

Coloured Inks. These are prepared very largely from coal-tar dyes, and it is now possible to produce ink of any desired tint or shade. Synthetic dyes have mostly replaced the vegetable colours previously used, besides which they are not nearly so costly. Their chief drawback is their want of permanence, especially on exposure to light and air. For the ordinary red writing inks the common dye eosine is generally used, the strength required being from 50 to 80 parts of water to one part of dye-stuff. It is unnecessary to use any gum or sugar, as such inks are perfectly fluid without such addition. Coloured printing inks are of increasing importance in consequence of the development of the three-colour and other processes. The more permanent mineral pigments are used where possible for reproducing coloured plates; but for certain colours, especially transparent colours in three-colour printing, nothing can replace certain of the aniline dyes, which are sufficiently permanent if carefully selected.

Copying and Typewriting Ink. Aniline dyes are generally used for copying inks, and invariably for typewriting inks, which are made so that they will copy. It is true that an ordinary writing ink will yield copies if taken at once, but if left over till the next day the ink will have oxidised and become fixed in the paper, and only the faintest copy will be procurable. Copying inks may be prepared according to the formulas for writing inks by suitable modification. They are rendered capable of being copied by the addition of such substances as gum, sugar, and glycerin in suitable proportions.

Miscellaneous Inks. Inks for rubber stamp pads are made from a suitable dye dissolved in a mixture of water 10 parts, acetic acid 10 parts, alcohol 10 parts, and glycerin 70 parts. Marking inks are usually metallic compounds, a metal, or some compound of the metal, being deposited on the fibre of the cloth, so that the writing will not wash out. For this purpose silver salts are suitable, a common method being to use a mixture of silver nitrate and tartaric acid or other substance, so as to form an easily reducible salt of silver. On passing a hot iron over the writing, the metallic silver is deposited. The following proportions are given by Dietrich: A solution of 25 parts silver nitrate, 15 parts gum, 60 parts ammonia solution, and two parts of lampblack or indigo, as a provisional colour.

PREPOSITIONS—continued

Meanings of Simple Prepositions

THE number of simple prepositions being very limited, every preposition is used to indicate different relations, as will be easily seen from the following examples:

Di. The preposition *di* is used to show the following relations:

1. MANNER—*Lo faccio di buona vòglia*, I do it willingly; *La sua lèttera mi è stata di gran sollievo*, Your letter has been of great comfort to me.

2. POSSESSION—*La casa di mio zio*, my uncle's house; *l'orològio di suo padre*, your father's watch.

3. PLACE—*L'università di Napoli*, the university of Naples.

4. ORIGIN—*Egli nacque di pòvera gente*, He was born of poor people.

5. CAUSE—*Mi dispiace di averle fatto male*, I am sorry to have hurt you.

6. MATTER—*Cappello di pàglia*, a straw hat; *panno di lana*, woollen cloth.

7. DENOMINATION—*La città di Londra*, the city of London.

8. MEASURE—*Un muro di tre metri*, a wall three metres high.

9. OBJECT—*Si parlava di lei*, We were speaking of you.

10. SUBJECT—*Il canto dell'usignuolo*, the song of the nightingale.

11. QUALITY—*Qualche cosa di buono*, something good.

Di is also used with adjectives and participles, which in English require the preposition *with*, as: *Un uomo contento del suo proprio stato*, a man contented *with* his own state; *Un àlbero càrico di frutta*, a tree loaded with fruit.

A. The preposition *a* is used to show the following relations:

1. MANNER—*a brandelli*, torn to pieces; *a memòria*, by heart.

2. TIME—*Vi leverete alle otto*, You shall get up at eight.

3. PLACE—*Vado a Parigi*, I am going to Paris.

4. DIRECTION—*A mezzogiorno, al sud*, towards the south.

5. DIRECTION OF ACTION—*Parlo a voi*, I am speaking to you.

6. PRICE—*L'ho comprato a una lira e l'ho venduto a due*, I bought it at one franc, and I have sold it at two.

7. OBJECT—*Amore allo studio*, love of study.

Da. The preposition *da* is used to show the following relations:

1. ORIGIN—*Arnaldo da Brèscia; San Francesco d' Assisi; La maggiòr parte dei guai provèngono dall' ignoranza*, Most troubles come from ignorance.

2. COMPLEMENT OF AGENT—*Amato da tutti*, loved by everyone.

3. TIME—*Sto a Londra da due anni*, I have been in London these two years.

4. USE—*Sala da pranzo*, dining-room; *carta da lettere*, writing paper.

[illegible] -*Vestito da donna*, female attire.

6. PLACE—*Vengo dalla città*, I come from the city; *dal libràio*, at the bookseller's; *Venite da me*, Come to me (to my house).

Da me, da te, da lui, da noi, etc., = to my house, to your house, to his house, to our house, etc. (Compare the French: *chez moi, chez toi*, etc.)

Da me, da te, da noi, etc., are used also as simple reciprocals: *L'ho fatto da me*, I did it myself—*i.e.*, without any assistance. (Compare the English, "by myself," etc.)

In. The preposition *in* is used to show the following relations:

1. MANNER—*Scrivete in lèttere: dieci sterline*, Write in letters: ten pounds.

2. TIME—*In quindici giorni*, in a fortnight; *in un' ora*, in an hour.

3. PLACE—*Egli è in Inghilterra*, He is in England; *Mio padre vive in campagna*, My father lives in the country.

4. OBJECT—*Ho fidùcia in lei*, I trust you.

5. MATTER—*Una stàtua in marmo, in bronzo*, a statue of marble, of bronze.

6. AIM—*Festa in onore di San Francesco*, a feast in honour of St. Francis.

Con. The preposition *con* is used to show the following relations:

1. MANNER—*Quella signora canta con molta gràzia*, That lady sings with much grace; *La pòvera donna rispose con le làcrime agli occhi*, The poor woman answered with tears in her eyes.

2. COMPANY AND COMBINATION—*Carlo era in giardino con suo fratello*, Charles was in the garden with your brother; *fràgole con crema*, strawberries with cream.

3. MEANS—*Andremo col battello*, We shall go by boat.

4. CAUSE—*Con questa nèbbia non si può vedère*, With this fog one cannot see.

5. INSTRUMENT—*Egli scrive sempre con penne d'oca*, He always writes with quill pens; *Lo tagli con il coltello*, Cut it with the knife.

Per. The preposition *per* is used to show the following relations:

1. TIME—*Devo esser fuori per le sette*, I must be out by seven.

2. PLACE—*Siamo venuti per mare*, We have come by sea.

3. CAUSE—*Tutto questo è accaduto per la tua indifferenza*, All this has happened through your indifference; *Molti giovani si rovìnano per il gioco*, Many young men ruin themselves by gambling.

4. DIRECTION—*Il treno per Roma è partito*, The train for Rome has gone.

5. INCLINATION—*Questo ragazzo ha una passione per la pittura*, This boy has a passion for painting.

6. PRICE—*L'ho venduto per cinque lire*, I have sold it for five francs.

7. MEANS—*Le spedisco i libri per pacco postale,* I am sending you the books by parcel post.

8. PURPOSE—*Mio figlio sta facendo dei risparmi per comprare un automòbile,* My son is saving some money to buy a motor-car; *Viàggio per divertirmi,* I travel to amuse myself.

9. DISTRIBUTION—*I ragazzi hanno avuto due soldi per uno,* The boys have had a penny each.

10. CONCESSION—*Per cattivo che un uomo sia, avrà sempre qualche buona qualità,* Howsoever bad a man may be, he always has some good quality.

11. IMAGINED QUALITY—*Mi prese per un francese,* He took me for a Frenchman.

ESERCÌZIO DI LETTURA—continued

Questa parola fece venìr le fiamme sul viso del frate: il quale però, col sembiante di chi inghiottisce una medicina molto amara, riprese: "lei non crede che un tal tìtolo mi si convenga. Lei sente in cuor suo che il passo ch'io fo ora qui non è nè vile nè spregèvole. M'ascolti, signòr don Rodrigo; e vòglia il cielo che non venga un giorno in cui si penta di non avermi ascoltato. Non voglia mèttere la sua gloria . . . qual gloria, signòr don Rodrigo! qual glòria dinanzi agli uòmini! E dinanzi a Dio? Lei può molto quaggiù; ma . . . ."

"Sa lei," disse don Rodrigo, interrompendolo con istizza, ma non senza qualche raccapriccio[1], "sa lei che, quando mi viene lo schiribizzo[2] di sentire una prèdica, so benìssimo andare in chiesa, come fanno gli altri? Ma in casa mia! Oh," e continuò, con un sorriso forzato di scherno: "lei mi tratta da più di quel che sono. Il predicatore in casa! Non l'hanno che i prìncipi."

"E quel Dio che chiede conto ai prìncipi della parola che fa loro sentire, nelle loro regge; quel Dio che le usa ora un tratto di misericòrdia, mandando un suo ministro, indegno e miseràbile, ma un suo ministro, a pregàr per una innocente. . . ."

"In somma, padre," disse don Rodrigo, facendo atto d'andàrsene, "io non so quel che lei vòglia dire: non capisco altro se non che ci dev' èssere qualche fanciulla che le preme molto[3]. Vada a far le sue confidenze a chi le piace; e non si prenda la libertà d'infastidìr[4] più a lungo un gentiluomo." (*Continued*).

NOTES: 1. fright; 2. whim; 3. in whom you are much interested; 4. to annoy.

IRREGULAR VERBS

Second Conjugation—continued

Verbs in **ëre** (short)—continued:

Erigere, to erect

Past Def.—Eressi, eresse, erèssero
Past Part.—Eretto

Espellere, to expel

Past Def.—Espulsi, espulse, espùlsero
Past Part.—Espulso

Esprimere, to express

Past Def.—Espressi, espresse, esprèssero
Past Part.—Espresso

Estinguere, to extinguish.

Past Def.—Estinsi, estinse, estìnsero
Past Part.—Estinto

Figgere, to fix

Past Def.—Fissi, fisse, fìssero
Past Part.—Fisso

Conjugate like *figgere:*

Affiggere, to stick; *prefiggere,* to prefix; *crocifiggere,* to crucify.

The following compounds of *figgere* end in the past participle in *itto: configgere,* to fix with nails, (*Past Part.—confitto*); *trafiggere,* to pierce (*Past Part.—trafitto*); *sconfiggere,* to defeat (*Past Part.—sconfitto*).

Also *figgere* may have the form *fitto* for the past participle.

Fingere, to feign

Past Def.—Finsi, finse, finsero
Past Part.—Finto

Frangere, to break

Past Def.—Fransi, franse, frànsero
Past Part.—Franto

Conjugate like *fràngere: infràngere,* to infract

Friggere, to fry

Past Def.—Frissi, frisse, frìssero
Past Part.—Fritto

Giungere, to arrive

Past Def.—Giunsi, giunse, giùnsero
Past Part.—Giunto

Conjugate like *giùngere: soggiùngere,* to reply; *aggiùngere,* to add; *congiùngere,* to join; *raggiùngere,* to overtake.

Immergere, to immerge

Past Def.—Immersi, immerse, immèrsero
Past Part.—Immerso

Conjugate like *immèrgere: emèrgere,* to emerge

Imprimere, to impress, to print

Past Def.—Impressi, impresse, imprèssero
Past Part.—Impresso

Indurre (*indùcere*), to induce [see *addùrre,* page 5081].

Infliggere, to inflict

Past Def.—Inflissi, inflisse, inflìssero
Past Part.—Inflitto

Leggere, to read

Past Def.—Lessi, lesse, lèssero
Past Part.—Letto

Conjugate like *lèggere: elèggere,* to elect

Mettere, to put

Past Def.—Misi (*messi*), *mise* (*messe*), *misero* (*mèssero*)
Past Part.—Messo

Conjugate like *mèttere: ammèttere,* to admit; *dimèttersi,* to discontinue; *commèttere,* to commit; *comprométtere,* to compromise; *dismèttere, smettere,* to leave off; *immèttere,* to insert; *intromèttere,* to place between; *frammèttere,* to interpose; *permèttere,* to permit; *promèttere,* to promise; *rimèttere,* to postpone; *scommèttere,* to bet; *sottomèttere,* to submit; *premèttere,* to premise.

Mungere, to milk

Past Def.—Munsi, munse, mùnsero
Past Part.—Munto

Muovere, to move

Past Def.—Mossi, mosse, mòssero

Conjugate like *muòvere: rimuòvere,* to remove; *commuòvere,* to move; *promuòvere,* to promote

Opprimere, to oppress [see *imprimere* above].

Percuotere, to percuss

Past Def.—Percossi, percosse, percòssero
Past Part.—Percosso

Piangere, to weep

Past Def.—Piansi, pianse, piànsero
Past Part.—Pianto

Conjugate like *piàngere: rimpiàngere,* to regret

Porgere, to hand, to offer

Past Def.—Porsi, porse, pòrsero
Past Part.—Pòrto (unused)

Porre (*pònere*), to put

Ind. Pres.—Pongo, poni, pone, poniamo, ponete, pòngono
Past Def.—Posi, ponesti, pose, ponemmo, poneste, pòsero
Future—Porrò, porrai, etc.
Imperat.—Poni, ponga, poniamo, ponete, pòngano
Subj. Pres.—Pongo, ponga, etc.
Condit.—Porrei, porresti, etc.
Past Part.—Posto

Conjugate like *pòrre: suppòrre,* to suppose; *compòrre,* to compose; *decompòrre,* to decompose; *depòrre,* to attest; *dispòrre,* to dispose; *indispòrre,* to indispose; *espòrre,* to expose; *frappòrre,* to interpose; *oppòrre,* to oppose; *presuppòrre,* to presuppose; *propòrre,* to propose; *sottopòrre,* to submit; *sovrappòrre,* to put upon; *predispòrre,* to predispose.

Exercise LI.

1. Dopo solo due ore di combattimento, il nemico fu completamente sconfitto. 2. Il treno di Parigi è giunto con quaranta minuti di ritardo. 3. Le due rive del fiume sono congiunte da un ponte di legno. 4. Il signor B. è stato eletto deputato con ottocento voti su mille. 5. Dove avete messo il mio ritratto? 6. Sembra che abbiate pianto, cosa è accaduto? 7. Non avrei mai supposto una cosa simile. 8. Se avete letto il libro che vi prestai, restituìtemelo. 9. Scommetto che questa volta perderete. 10. Ho promesso a mio padre di èssere più diligente ed egli mi ha permesso di uscire.

Conversazione

Quando ha deciso di partire, questa settimana o l'altra?

Secondo (*that depends*), non so precisamente.

Dov' è la galleria Umberto I.?

Dirimpetto al teatro San Carlo.

Con chi era ieri sera al Caffè?

Ero con un signore americano, che àbita dirimpetto a noi.

Dove va? (*where are you going?*) Segga vicino a me, non mi lasci qui solo solo.

Non ho tempo: ho lezione alle dieci e mezzo.

Prende lezione tutti i giorni?

Sì, eccetto il giovedì.

Cosa n'è di quel tipo che prendeva lezione insieme con lei?

Non l'ho più visto; credo che sia ritornato in Germània.

Key to Exercise XLIX.

1. You will never learn anything, because you always play during the lesson. 2. Instead of one hundred francs we have received only fifty. 3. The villa of which I have spoken to you is on the other side of the Thames. 4. We have been obliged to postpone our departure till Monday for want of money. 5. If you are cold, sit near the fire. 6. Opposite to us there is a house to let. 7. Take care, my hat is there: do not sit on it. 8. Except these two, all the other pictures are worth nothing. 9. Let us speak openly, there must be no mysteries between us. 10. I will do it for your sake. 11. More than forty people remained buried under the ruins.

Key to Exercise L.

1. A good tree produces good fruit. 2. When I untie the parcel, you may choose what you like best. 3. What have you chosen? 4. The petition was signed by nearly one hundred persons. 5. My brother has written me a long letter. 6. If Mr. M. had not protected you, you would not now occupy this place. 7. The poor child is crying because she has pricked her finger with a needle. 8. Press the button to call the waiter.

By Louis A. Barbé, B.A.

SYNTAX—THE ARTICLE

The Definite Article. 1. The definite article is required before all nouns used in their widest sense—that is to say, in a way that includes all the individuals or objects of a given class: *Les métaux sont plus utiles aux hommes que les diamants et les pierreries,* Metals are more useful to men than diamonds and precious stones.

2. In accordance with this principle (*a*) abstract nouns, and (*b*) nouns indicating material take the definite article: *L'hypocrisie est un hommage que le vice rend à la vertu,* Hypocrisy is a homage that vice pays to virtue. *Le platine est plus pesant que l'or,* Platinum is heavier than gold.

Exception: Sometimes an abstract noun and a preposition are equivalent to an adverb, and a noun of material and a preposition to an adjective; in such cases, no article is used: *Travaillez avec modération pour travailler longtemps,* Work with moderation so as to work long; *On dit qu'Henri II. fut le premier qui porta des bas de soie,* It is said that Henry II. was the first to wear silk stockings.

3. When one individual is taken to represent a whole class, the definite article is required: *Dieu dit ensuite: Faisons l'homme à notre image et à notre ressemblance,* Then God said: Let us make man in our image and likeness.

4. Titles immediately preceding proper nouns require the definite article: *Le règne de la reine Victoria en est un des plus longs de l'histoire; il est moins long cependant que celui du roi Louis XIV.,* Queen Victoria's reign is one of the longest in history; it is shorter, however, than that of King Louis XIV.

5. The article is used, in familiar language, before such words as *ami, homme, mère,* in addressing a person whose name is not known: *Ohé! l'ami, venez ici,* Hallo! friend, come here.

6. When proper nouns are qualified by an adjective, that adjective must be preceded by the definite article: *La pâleur du petit Pierrot inquiétait fort la vieille Marguerite,* Little Pierrot's pallor greatly troubled old Margaret.

7. The definite article is sometimes prefixed to the names of individuals to indicate familiarity, celebrity, or notoriety. With regard to men, this is almost exclusively limited to famous Italian writers and painters: *Le Pulci, le Bojardo, l'Arioste,* &c. The article is sometimes used in speaking of certain women widely known, either for good or for evil: thus, *la* Champmeslé, a famous actress; *la* Brinvilliers, a notorious poisoner.

8. The definite article is used with names of seasons and feasts, except Easter and, usually, Christmas: *le printemps,* spring; *le vendredi*

saint, Good Friday. In many cases, the feminine article *la* is used in connection with a masculine saint's name, the feminine word *fête* being understood: *la Saint-Jean*, St. John's (mid-summer) day: *Astronomiquement, l'automne est l'espace de temps du vingt septembre au vingt et un décembre*, Astronomically, autumn is the space of time from the 20th of September to the 21st of December; *La Pentecôte se célèbre cinquante jours après Pâques*, Pentecost is celebrated fifty days after Easter.

9. Days of the week take the definite article (*a*) when they are immediately followed by a date, or (*b*) to indicate a day set apart for the regular recurrence of some action: *Les États généraux se réunirent à Versailles le mardi cinq mai*, 1789, The States General met at Versailles, Tuesday, 5th of May, 1789; *Il se repose le lundi de n'avoir rien fait le dimanche*, He rests on Mondays for having done nothing on Sundays.

Exception: The days of "last week" and "next week" take no article: *Il est parti samedi dernier et il doit revenir jeudi prochain*, He left last Saturday, and he is to return next Thursday.

10. The definite article is used in the "absolute construction"—that is to say, before a noun not governed by any word in the sentence: *Nous apercevions les grenadiers, l'arme haute, l'œil gauche attaché sur nous, le droit caché par le fusil élevé*, We perceived the grenadiers, with levelled muskets, the left eye fixed upon us, the right hidden by the raised gun.

11. The definite article, with the preposition *à*, is used to express some peculiarity or distinctive feature: *Il y avait parmi les passagers, de jeunes Anglaises aux brillantes spirales de cheveux blonds*, There were amongst the passengers some young English girls with brilliant coils of fair hair.

12. In descriptions of personal appearance, the verb *avoir* and a noun with a definite article are frequently used: *Elle a les cheveux blonds, les yeux bleus, le teint frais, les dents blanches, et les lèvres vermeilles*, She has fair hair, blue eyes, a fresh complexion, white teeth, and ruddy lips.

13. The definite article is used in connection with *vers* or *sur* in expressions of approximate time: *Il est sorti vers le midi; il rentrera sur les six heures*, He went out about noon; he will come back about six.

14. The definite article is used distributively to express measure and weight: *Ce vin coûte deux francs la bouteille*, This wine costs two francs a bottle.

NOTE: In expressions of time, the preposition *par* is used instead of the article: *Son traitement est de huit cents francs par mois*, His salary is 800 francs a month.

15. The definite article is used before the names of continents, countries, and provinces: *La Suisse, la Belgique, le Danemark et le Portugal ne sont pas au nombre des grandes puissances de l'Europe*; Switzerland, Belgium, Denmark and Portugal are not amongst the great powers of Europe.

Exception: After the preposition *de*, the definite article is not used when it is intended to form an adjective phrase only: *La plupart des vins de France sont moins forts que ceux d'Espagne et de Portugal*; The greater part of French wines are less strong than those of Spain and of Portugal.

16. The definite article is used with the names of mountains, seas, and rivers: *Le Vésuve, célèbre volcan d'Italie, a onze cent quatre vingt-dix mètres de hauteur*, Vesuvius, a celebrated volcano in Italy, is eleven hundred and ninety metres high.

17. With feminine names of countries, "in" and "into" are expressed by *en* without the definite article. The article is also omitted, and the preposition *de* used alone, after verbs expressing coming from those countries, such as *arriver de, venir de*, etc.: *S'il part d'Amérique le vingt-trois juin, il arrivera en Europe vers le premier juillet*, If he leaves America on the 23rd of June, he will arrive in Europe about the 1st of July.

18. The definite article is not used before numerals denoting the order of succession of sovereigns, etc. It is also omitted before nouns in apposition: *Louis seize, petit-fils et successeur de Louis quinze, monta sur le trône en* 1774, Louis the Sixteenth, the grandson and successor of Louis the Fifteenth, ascended the throne in 1774.

19. The definite article is not used in French, as it is in English, when a comparative is repeated:

Plus vous serez gai, plus longtemps vous vivrez, The gayer you are, the longer you will live.

Translation

[Words which have already been used, and words which are either identical or very similar in the two languages, are not given in the vocabularies.]

actuel, actual, present-day, modern
ajouter, to add

part (à), apart, special
quant à, as to, with regard to
répartir, to divide
revanche (en), by way of compensation
Suisse (f.), Switzerland
sur, on, out of

GÉOGRAPHIE DE LA LANGUE FRANÇAISE

La langue française comprend tout le domaine de la France actuelle, à l'exception d'une seule province, la Bretagne, où un million d'habitants sur un million huit cent mille parlent une langue connue sous le nom de bas-breton et qui est d'origine celtique. A cette exception importante, on peut encore ajouter trois petits groupes: le département du Nord, où deux cent mille habitants (sur un million deux cent mille) parlent la langue flamande, qui est d'origine allemande; le département des Basses-Pyrénées, où cent vingt mille habitants parlent le basque, idiome fort ancien, dont l'origine est inconnue; enfin le département des Pyrénées-Orientales (ancienne province de Roussillon), où cent trente mille habitants parlent la langue catalane, qui est dérivée du latin.

Si le domaine de la langue française ne s'étend pas sur tout le territoire actuel de la France, en revanche elle comprend à l'étranger plusieurs territoires importants, représentant un peu plus de trois millions six cent mille habitants, ainsi répartis ; pour la Belgique un million six cent mille habitants ; pour l'empire d'Allemagne un million (Alsace-Lorraine) : pour la Suisse française quatre cent mille : enfin soixante mille pour les Îles Normandes, qui appartiennent à l'Angleterre.

A ces chiffres il faut ajouter, hors d'Europe, les colonies anglaises du Canada et de l'Ile Maurice, qui ont conservé l'usage du français, sans parler de nos propres colonies (Algérie, Guyane, Sénégal, etc.). C'est un appoint d'un peu plus d'un million cinq cent mille habitants à joindre au domaine linguistique français. (AUGUSTE E. BRACHET.)

The Indefinite Article. 1. The indefinite article is required in French, though not necessary in English, before an abstract noun used partitively and qualified by an adjective. *Ils ont supporté toutes les fatigues et toutes les privations avec une constance admirable*, They bore every fatigue and every privation with admirable constancy.

2. The indefinite article is not used after *quel*, what, nor after *sans*, without : *Quelle foule de maux l'ambition traîne à sa suite*, What a multitude of evils ambition drags in its train. *Je ne puis écrire sans plume*, I cannot write without a pen.

3. The indefinite article is usually omitted before a noun preceded by *jamais*, never: *Jamais homme n'a eu plus de succès avec aussi peu de mérite*, Never has a man had more success with so little merit.

4. The indefinite article is not used before nouns in apposition : *Nelson, célèbre amiral anglais, naquit en* 1758, Nelson, a famous English admiral, was born in 1758.

5. The indefinite article, though used in English, is omitted in French before nouns serving as predicative complements to such verbs as *être*, to be ; *devenir*, to become : and *paraître*, to seem ; and also before nouns serving as the second accusative after such verbs as *faire*, to make ; *se faire*, to become : *se montrer*, to show oneself ; *nommer*, to appoint ; *croire*, to believe : *Le père du maréchal Ney était tonnelier*, Marshal Ney's father was a cooper. *Montrez-vous bon ami*, Show yourself a good friend.

6. When *comme*, "as," means "in the capacity of," the noun that follows it does not take the indefinite article. The indefinite article is required before the noun following *comme* if that noun is the subject of a verb understood : *Ney fit les deux premières campagnes de la Révolution comme aide de camp*, Ney went through the first two campaigns of the Revolution as aide-de-camp. *Le pauvre vieillard se laissait tromper comme un enfant*, The poor old man allowed himself to be deceived like a child.

7. No indefinite article is required after fractional numbers : *Il a mis un quart d'heure à écrire une demi-page*, He has taken a quarter of an hour to write half a page.

The Partitive Article. 1. The partitive article *du, de la, des* is used regularly before any noun indicating a certain portion of any thing or a limited number of objects, whether the English equivalents "some" and "any" be expressed or only understood : *J'ai passé des jours heureux à la campagne*, I have spent (some) happy days in the country.

2. Before a noun preceded by an adjective, the preposition *de* alone is to be used : *De riantes prairies s'offraient à nos regards charmés*, Smiling meadows presented themselves to our delighted gaze.

3. If the adjective and the noun are so closely connected as practically to constitute a single word, whether joined by a hyphen or not, the article is to be used as well as *de* : *Il y a des belles-mères qui valent de véritables mères*, There are step-mothers who are as good as real mothers.

4. When a noun taken partitively is the object of a negative sentence, *de* alone is to be used : *Je n'ai pas d'argent*, I have not any money.

5. In English negative sentences, the indefinite article frequently has the meaning of "any," and must accordingly be translated by *de* ; *Il ne porte jamais de chapeau*, He never wears a hat.

6. Before an adjective the partitive article is used to indicate distinction or opposition. Thus, *Donnez-moi de bon pain* means simply, Give me some good bread : but, *Donnez-moi du bon pain* means, "Give me some of the good bread "—that is to say, there are two kinds of bread, good and bad, I want some of the good kind.

7. In negative sentences, the definite article is to be used before the complement, if that complement is followed by an adjective or an adjective clause. Thus, *Je n'ai pas d'argent* means I have no money ; but, *Je n'ai pas de l'argent pour le dépenser follement*, I have no money to spend extravagantly, implies that I have money, but that it is not to be squandered.

8. In a negative-interrogative sentence, the use of the partitive implies that an affirmative answer is expected. Thus, *N'avez-vous pas d'amis à Paris ?* Have you no friends in Paris ? is a genuine question, asked in order to obtain information. On the contrary, *N'avez-vous pas des amis à Paris ?* implies a belief, or even an assertion, that there are such friends, and may be translated, You have friends in Paris, have you not ?

9. The partitive article, or the preposition *de* standing instead of it, may be used after any preposition except *de* ; *Avec de la patience et de la persévérance tout est possible*, With patience and perseverance everything is possible.

Place of the Article. 1. The article precedes the noun, but an adjective, a numeral, or *quelques*, meaning "few," may occur between it and the noun : *Le célèbre satirique Pope était bossu*, The celebrated satirist Pope was a hunchback. *Je ne regrette pas les quelques francs que cela m'a coûté*, I do not regret the few francs which that has cost me.

2. *Tout* (*toute, tous, toutes*) is the only adjective which, when accompanied by an article, always precedes it : *Il a perdu toute l'affection qu'il avait pour moi*, He has lost all the affection which he had for me.

3. The adjective *feu*, late (deceased) may either precede or follow the article. When it precedes it, there is but the one form for both genders : *La feue reine était aimée et respectée de tous ses sujets*, The late queen was loved and respected by all her subjects. *Ma mère est née la même année que feu la reine Victoria*, My mother was born in the same year as the late Queen Victoria.

KEY TO EXERCISE XXXVII.

1. Le paresseux travaille malgré lui.
2. Le soleil luit pour tout le monde.
3. Travaillez avec zèle : le travail est la source de l'abondance et de la joie.

4. L'invention du téléphone est due à Graham Bell et celle du phonographe à Edison.

5. De Calais quand le temps est clair, vous apercevez Douvres vis-à-vis de vous.

6. Apprenez que suivant le dire d'un ancien, il faut manger pour vivre et non pas vivre pour manger.

7. Ecrivez les injures sur le sable et les bienfaits sur l'airain.

8. Je crains Dieu, et, après Dieu, je crains principalement ceux qui ne le craignent pas.

9. Il faut tâcher de bien vivre avec tout le monde.

10. Il travaille toute la semaine excepté le dimanche.

11. Un enfant bien élevé ne doit rien faire malgré ses parents.

12. Les vacances commenceront dans moins de deux mois.

13. Votre oncle ne sait peut-être pas où est notre maison ; allez au-devant de lui et amenez-le si vous le voyez.

14. Un des romans de Jules Verne a pour titre, "Le Tour du Monde en quatre-vingts Jours."

15. Mettons-nous sous cet arbre, nous y serons à l'abri de la pluie.

16. Il dut la vie à la clémence et à la magnanimité du vainqueur.

17. Remplissez vos devoirs envers Dieu, envers vos parents et envers la patrie.

18. On trouve les mêmes préjugés en Europe, en Afrique et jusqu'en Amérique.

KEY TO EXERCISE XXXVIII.

1. La charité est patiente, douce et bienfaisante.

2. La boussole n'a point été trouvée par un marin ni le télescope par un astronome.

3. Ni l'or ni la grandeur ne nous rendent heureux.

4. L'homme n'est malheureux que parce qu'il est méchant.

5. Obéis si tu veux qu'on t'obéisse un jour.

6. Les hirondelles partent dès que les premiers froids arrivent.

7. On ne croit plus un enfant quand il a menti.

8. Si l'eau bout plus tôt sur les hautes montagnes, c'est parce que la pression de l'air y est moins forte.

9. Tous les hommes sont mortels ; or, vous êtes un homme ; donc vous êtes mortel.

10. S'il vient en France et qu'il passe par Paris, je serai charmé de le voir.

11. La terre ne s'épuise jamais pourvu qu'on sache la cultiver.

12. Conduisez-vous de telle sorte que tout le monde soit content de vous.

By Harald Clegg

THE ACCUSATIVE

Motion. As has been shown [page 4655] the prepositions govern the nominative case, but when motion is indicated, it sometimes happens that the preposition used does not sufficiently contain all that is necessary to show the full extent of the movement, which may be either physical or moral. If we say "The bird flew under the table," it is not clear whether we mean that the bird, being there, flew about under the table or that it flew there from outside. To express the latter idea, however, Esperanto uses the accusative, even though there is a preposition before *tablo*, and thus indicates movement. The prepositions *al* (to) *ĝis* (up to, as far as), and *tra* (through) containing in themselves the full idea of motion, do not, in such cases, require the use of the accusative.

The following sentences illustrate the peculiar use of the accusative of direction.

En la mondon venis nova sento, Into the world a new feeling has come.

Mi saltis sur la muro, I jumped on the wall (I was there).

Mi saltis sur la muron, I jumped upon the wall (from elsewhere).

La lampo pendas super la tablo, The lamp hangs above the table.

Mi ĵetis la ŝtonon super la domon, I threw the stone above the house.

Li vojaĝis trans la maron, ĉar trans la maro li havis amikojn, He travelled across the sea, as across the sea he had friends.

Mi verŝis la inkon en la tason, kaj nun la inko restas en la taso, I tilted the ink into the cup, and now the ink remains in the cup.

This accusative of direction must, in similar circumstances, be applied to adverbs. Example:

La ŝtono falis teren, The stone fell to earth.

Nun, ni iros hejmen, Now we will go home.

Antaŭen ! Forward ! To the front !

Accusative Instead of Preposition. It is customary with intransitive verbs, when ideas of direction, time, price, weight, or measure are expressed, to omit the preposition and straightaway adopt the accusative, as in the following phrases :

Mi iras Berlinon, I am going to Berlin.

Mi restos tie tri semajnojn, I shall stay there three weeks.

Mi alvenos tie proksiman lundon, la 10an de Majo, I shall arrive there next Monday, the 10th of May.

La tablo estas longa dudek futojn ; ĝi pezas du cent funtojn kaj kostas naŭdek ŝilingojn, The table is twenty feet long ; it weighs two hundred pounds, and costs ninety shillings.

In all cases similar to the above, the accusative can, however, be dropped, and a suitable preposition be found.

PREFIXES

The remaining prefixes are as follow :

Ek denotes the beginning of an action or its momentary duration. Example :

Dormi, sleep ; *Ekdormi*, fall asleep.

Krii, cry ; *Ekkrii*, cry out suddenly.

Ge denotes the inclusion of both sexes. Example :

Frato, brother ; *gefratoj*, brother (s) and sister (s).

Mastro, master ; *gemastroj*, masters (s) and mistress (es).

Note that the use of *ge* always requires the plural.

Re denotes that an action is repeated or returned once. Example :

Sendi, send ; *resendi*, send back, return.

Trovi, find ; *retrovi*, recover, retrieve.

VOCABULARY

akompan'	accompany

EXERCISE IX.

A year has twelve months; July is the seventh. It has thirty-one days, and follows June. The remaining months are January, February, March, April, May, August, September, October, November, and, lastly, grey and dull December. Son and daughter. Brother and sister. Nephew and niece. Grandfather and grandmother. Man and woman. Mr. and Mrs. Fiancé and fiancée. He flatters himself, but he did not convince me. She burst out laughing. I begin to think that you wish to deceive me. My grandson sent the letter back to me. She wrote on a piece of paper. I looked for the butter, and finally found it under the newspaper. I fell on my knees, and swore that I had given back the money. In the morning (morningly) the sun is seen (one sees) in the east. In the evening (eveningly) it is in the west. The cage hangs on the wall outside the house. She quietly put the liquid back into the bottle. My cousins (*m.* and *f.*) fed the fishes. The leaf fell from the tree to the ground. He fell into the river. They accompanied him as far as the theatre. They endeavoured to comfort her, but could not. The best of us must die and return to earth through the grave. A terrible wind began to blow, and the clouds hid the sun.

KEY TO EXERCISE VIII.

Mi tre bedaŭras aŭdi pri la morto de via frato. Oni diras al mi ke vi ne fartas tiel bone hodiaŭ kiel hieraŭ. Kvankam la reĝo estas gracia kaj fortika, li estas fiera kaj tiel kruela, kiel la plej sovaĝa besto. Nia lando estas la plej kara kaj bela en la tuta mondo. Mi ne pensas ke mi estas ĵaluza, sed mi vere kredas ke ŝi adoras min pli ol vin. Ili komencis libere diskuti kaj disputi pri niaj metodoj, sed mi devas konfesi, ke mi ne povis esprimi mian aprobon. Ĉu vi povas direkti min al la teatro ? Jes, sinjoro, kun plezuro (*or*, plezure). Jen ĝi estas, maldekstre. La suno, alta en la ĉielo, varme brilas. Mi estas ĝuste tiel laca kiel vi mem, sed ne tiel malĝentila. Li konstruis altan domon el ŝtono. Via ideo estas tre bona kaj interesa, sed ĝi estas neoportuna. En nia lando la popolo estas libera. Ili malfeliĉe perdis grandan nombron da amikoj. Mi miras, ke mi ne renkontis vin kaj viajn amikojn kune. Mi pardonis lin, sed li fiere foriris kaj fermis la pordon. Floroj kreskas dum la tuta jaro.

GREEK

By G. K. Hibbert, M.A.

Classical and Modern Greek

Greek is the language spoken by the Greek race. When we pass from the period of myth, or semi myth, of which the poems of Homer are a record (before 850 B.C.), to the historic period, we find the Greek race divided into Dorians, Æolians, and Ionians, each speaking their own dialect. These dialects are called respectively Doric, Æolic, and Ionic. Classical Greek consists of that form of the Ionic dialect which was spoken in Athens during the period of her literary eminence (500 to 300 B.C.): it is called Attic, from Attica, the district in which Athens was situated. Modern Greek is very like the Greek of the classical period, and Demosthenes or Plato would be able to read without difficulty the newspapers now published in Athens. Few languages have had such a glorious history, and none other perhaps has so influenced the thought of the world.

At the outset, the student is recommended to procure a good Greek dictionary, and for general purposes Liddell and Scott's Abridged Greek-English Lexicon (Clarendon Press, price 7/6) cannot be improved upon.

The Alphabet. The Greek alphabet has twenty-four letters.

NAME		FORM		ENGLISH EQUIVALENT
Alpha	Ἄλφα	Α	α	a
Beta	Βῆτα	Β	β	b
Gamma	Γάμμα	Γ	γ	g
Delta	Δέλτα	Δ	δ	d
Epsilon	Ἒψιλόν	Ε		e (*short*)
Zeta	Ζῆτα	Ζ	ζ	z
Ēta	Ἦτα	Η	η	e (*long*)
Theta		Θ	θ	th
Iota		Ι	ι	
Kappa		Κ	κ	k, *or hard* c
Lambda		Λ	λ	l
Mu	Μῦ	Μ	μ	m
Nu	Νῦ			n
Xi	Ξῖ			x
Omicron	Ὂμι			o (*short*)
Pi	Πῖ			p
Rho	Ῥῶ			r
Sigma				s
Tau	Ταῦ			t
Upsilon	Υ̓̀ψ			u *or* y
Phi	Φῖ			ph
Chi	Χῖ			kh
Psi	Ψῖ			ps
Omega				

NOTES: 1. *Omicron* means literally "*little o,*" and *Omega* means "*great o.*"

2. With regard to *Sigma*, at the end of a word the form used is ς, elsewhere the form is σ—*e.g.* πίστις, pistis (faith).

3. The vowels are α, ε, η, ι, ο, ω, υ. Of these ε and ο are always short; η and ω always long; α, ι, υ sometimes long, sometimes short.

4. ξ, ψ, and ζ are *double* consonants, the first being composed of κ and σ, the second of π and σ (as in psalm), and the third of δ and σ.

Pronunciation. We have not a complete account of ancient Greek pronunciation, and there is no uniform standard of pronunciation of Greek in Great Britain and the United States. Some boldly adopt the "English" pronunciation, and sound the words exactly as they would be sounded in English. But the following system is far more correct, and may be adopted for all practical purposes:

Pronounce	Pronounce
α as *a* in *father*	ο as *o* in *not*
ε as *e* in *ten*	ω as *o* in *note*
η as *a* in *late*	υ as the French *u*.
ι as *i* in *machine*	

Pronounce the consonants as in English, except that γ before κ, ξ, χ, or another γ has the sound of *n* (ἄγγελος = *angelos*, messenger, angel); elsewhere γ is always hard.

θ is pronounced like *th* in *thin*, ζ like soft *ds* (not quite like the English *z*), and χ is always hard, like the German *ch*.

The diphthongs may be pronounced much as their English equivalents, except that αυ = *ou* in *house*, and ου = *ou* in *uncouth*.

Breathings. Every word that begins with a vowel or a diphthong has a "breathing" over the vowel or diphthong. The breathing is either *smooth* ('), like an apostrophe, or *rough* (')—*e.g.*: ἰχθύς = *ichthus*, fish; ὁδός = *hodos*, road. The rough breathing shows that the vowel is aspirated, while the smooth breathing shows that it is not aspirated.

A diphthong takes the breathing upon its *second* vowel—*e.g.*: αὐτός, υἱός (= *huios*, son).

When the consonant ρ (*r*) begins a word it is generally written with a rough breathing, ῥ—*e.g.* ῥόμβος (rhombus), ῥόδον (rose), while ρρ in the middle of a word is generally written ῤῥ—*e.g.*: Πύῤῥος, Pyrrhus.

Punctuation Marks. Greek uses the *comma* and the *full-stop*, like English. It uses also a *colon*, a single point above the line (·), the equivalent of the English colon and semicolon. The mark of interrogation in Greek (;) is identical in form with the English semicolon.

Accents. The student will have noticed that every Greek word hitherto mentioned has an accent of some kind marked over it—*e.g.*: αὐτός, Βῆτα. (The accent is additional to the breathing in words beginning with a vowel.) The Greek system of accents is however rather complicated, and had better be treated later on. Meanwhile, the student can write his Greek without the accents, though taking care to put in the breathings correctly. The marks of accent were invented for the purpose of teaching foreigners the correct pronunciation of Greek.

EXERCISE I.

Write the following Greek words in English letters: ῥοδόδενδρον, διάγνωσις, ἄγκυρα, μεταμόρφωσις, καταστροφή, παντόμιμος, Ξέρξης, Σωκράτης, ψαλτήριον.

NOUNS

There are three declensions of nouns and adjectives, corresponding roughly to the first three declensions in Latin. The first is called the *A* declension, and the second the *O* declension. These two are the *Vowel* declensions, as opposed to the third, which contains all nouns not of the first or second, and is sometimes called the *Consonant* declension.

Nouns are declined for number and case; adjectives for number, gender, and case. The *numbers* are three: singular, dual, and plural. The dual is used to denote two objects, but its use is not frequent, and it is generally replaced by the plural.

The *genders* are three: masculine, feminine, and neuter. In Greek, as in Latin, the gender of a noun is often determined by its ending, not, as in English, by its meaning. Thus οἰκία (house), is feminine, although *house* is neuter in English. Names of males, however, are generally masculine, and names of females feminine. Most names of rivers, winds, and months are masculine; of countries, towns, trees, and islands, feminine, as also are most nouns denoting qualities or conditions—*i. e.*, abstract nouns.

The *Cases* are five:

	Answers the question:
1. *Nominative*	Who *or* what?
2. *Vocative*	(Case of the person addressed).
3. *Accusative*	Whom *or* what?
4. *Genitive*	Whose *or* whereof?
5. *Dative*	To, for, by, with whom, *or* what?

NOTES: 1. The Latin ablative is replaced in Greek by the genitive and dative.

2. The nominative and vocative plural are always alike.

3. In neuter nouns, the nominative, vocative, and accusative are alike in all numbers; and in the plural of neuter nouns these three cases always end in α.

4. The nominative, vocative, and accusative dual are always alike; and so are the genitive and dative dual.

First Declension Nouns: A STEMS. Masculine nouns of this declension end in ας or ης; and feminine nouns end in α or η.

The masculine nouns are declined like the two following: νεανίας (young man), πολίτης (citizen).

	Singular	
Nom.		
Voc.		
Acc.		
Gen.	νεανίου	πολίτου
Dat.	νεανίᾳ	πολίτῃ
	Dual	
Nom., Voc., Acc.	νεανία	πολίτα
Gen., Dat.	νεανίαιν	
	Plural	
Nom., Voc.	νεανίαι	
Acc.	νεανίας	
Gen.	νεανιῶν	πολιτων
Dat.	νεανίαις	πολίταις

NOTE. The little ι written under the last letter of the dative singular is called *iota subscript*. The dative originally ended in ι, as νεανίαι, πολίτηι; but the ι is now always written below the other vowel.

Like one or other of the two nouns given above decline ταμίας, steward; κριτής, judge; ναύτης, sailor; δεσπότης, master; Πέρσης, a Persian; γεωμέτρης, geometer; and στρατιώτης, soldier.

Feminine nouns of this declension are declined like the four following: ψυχή (soul), οἰκία (house), χώρα (land), θάλασσα (sea).

Singular

Nom. *Voc.*	ψυχή	οἰκία	χώρα	θάλασσα
Acc.	ψυχήν	οἰκίαν	χώραν	θάλασσαν
Gen.	ψυχῆς	οἰκίας	χώρας	θαλάσσης
Dat.	ψυχῇ	οἰκίᾳ	χώρᾳ	θαλάσσῃ

Dual

N., V., A.	ψυχά	οἰκία	χώρα	θαλάσσα
Gen. Dat.	ψυχαῖν	οἰκίαιν	χώραιν	θαλάσσαιν

Plural

Nom., Voc.	ψυχαί	οἰκίαι	χῶραι	θάλασσαι
Acc.	ψυχάς	οἰκίας	χώρας	θαλάσσας
Gen.	ψυχῶν	οἰκιῶν	χωρῶν	θαλασσῶν
Dat.	ψυχαῖς	οἰκίαις	χώραις	θαλάσσαις

NOTE. 1. Nouns ending in α preceded by ε, ι, or ρ, retain the α throughout the singular, and are declined like οἰκία or χώρα. Other nouns ending in α are declined like θάλασσα, unless the α is a contracted form of αα, as μνᾶ (*a mina*), contracted from μνάα (gen. μνᾶς, dat. μνᾷ).

2. The vocative of Ἑρμῆς (the god Hermes, or Mercury) is Ἑρμῆ, not Ἑρμα.

Second Declension Nouns: O STEMS. Masculine nouns of this declension mostly end in ος, neuters in ον. There are very few feminine nouns of this declension, and these few end in ος, like the masculine.

Singular

Nom.	λόγος (word)	δῶρον (gift)
Voc.	λόγε	δῶρον
Acc.	λόγον	δῶρον
Gen.	λόγου	δώρου
Dat.	λόγῳ	δώρῳ

Dual

Nom., Voc., Acc.	λόγω	δώρω
Gen., Dat.	λόγοιν	δώροιν

Plural

Nom., Voc.	λόγοι	δῶρα
Acc.	λόγους	δῶρα
Gen.	λόγων	δώρων
Dat.	λόγοις	δώροις

Like one or other of these, decline ἄνθρωπος, man; νόμος, law; κίνδυνος, danger; πόταμος, river; βίος, life; θάνατος, death; δοῦλος, slave; ἵππος, horse; πόλεμος, war; στρατηγός, general; διδάσκαλος, teacher; ὁδός (f.), road; νῆσος (f.), island; σῦκον, fig; ἱμάτιον, outer garment; ζῶον, animal; τόξον, bow; and δένδρον, tree (except that dative plural is δένδρεσι). The vocative of Θεός, god, is Θεός. Many nouns in εος, οος, and οον of this declension are contracted. Thus νόος, mind (νοῦς); ὀστέον, bone (ὀστοῦν).

Singular

Nom.	νοῦς	ὀστοῦν
Voc.	νοῦ	ὀστοῦν
Acc.	νοῦν	ὀστοῦν
Gen.	νοῦ	ὀστοῦ
Dat.	νῷ	ὀστῷ

Dual

Nom., Voc., Acc.	νώ	ὀστώ
Gen., Dat.	νοῖν	ὀστοῖν

Plural

Nom., Voc.	νοῖ	ὀστᾶ
Acc.	νοῦς	ὀστᾶ
Gen.	νῶν	ὀστῶν
Dat.	νοῖς	ὀστοῖς

A few nouns of this declension end in ως (masculine and feminine) and ων (neuter). This is sometimes called the Attic declension. Thus νεώς, temple (masc.), and ἀνώγεων, hall (neuter).

Singular

Nom., Voc.	νεώς	ἀνώγεων
Acc.	νεών	ἀνώγεων
Gen.	νεώ	ἀνώγεω
Dat.	νεῴ	ἀνώγεῳ

Dual

Nom., Voc., Acc.	νεώ	ἀνώγεω
Gen., Dat.	νεῴν	ἀνώγεῳν

Plural

Nom., Voc.	νεῴ	ἀνώγεω
Acc.	νεώς	ἀνώγεω
Gen.	νεών	ἀνώγεων
Dat.	νεῴς	ἀνώγεῳς

THE ARTICLE

There is no indefinite article in Greek, but there is a definite article ὁ, *the*, which is declined as follows:

	Singular			*Dual*			*Plural*		
	Masc.	*Fem.*	*Neuter*	*Masc.*	*Fem.*	*Neuter*	*Masc.*	*Fem.*	*Neuter*
N.	ὁ	ἡ	τό	τώ	(τά)	τώ	οἱ	αἱ	τά
A.	τόν	τήν	τό	,,	,,	,,	τούς	τάς	τά
G.	τοῦ	τῆς	τοῦ	τοῖν	(ταῖν)	τοῖν	τῶν	τῶν	τῶν
D.	τῷ	τῇ	τῷ	,,	,,	,,	τοῖς	ταῖς	τοῖς

It will be noticed that the feminine is declined like an η noun of the first declension (ψυχή), and the masculine and neuter almost exactly like a masculine and a neuter noun of the second declension respectively (λόγος and δῶρον). The feminine dual forms τά and ταῖν (especially τά) are rare; τώ and τοῖν are generally used for all genders. The definite article agrees with its noun in number, gender and case, as: ἡ κόρη, the girl; τὰ ὀστᾶ, the bones; ταῖς οἰκίαις, for the houses.

EXERCISE II.

Put into Greek: 1. Of the young man. 2. To the bones. 3. The sailor (accusative). 4. Of the two soldiers. 5. Of the law. 6. To the animal. 7. The rivers. 8. To the citizens. 9. Of the temple. 10. The fig (accusative). 11. Of the island. 12. The girls.

THE COMMERCIAL HIGHWAYS OF THE WORLD

The ocean route distances are given in *statute* miles (69 = 1°) instead of the more usual *nautical* miles, or knots (60 = 1°), so that they can be correctly compared with those of the trans-continental routes here would be nothing to "prove," nothing o "select." The more one contemplates this great saying of St. Augustine's, and the more that, in the light of the idea of the social organism, we compare social forces with those that act amongst individual organisms, the more impressed must we become with the beauty of the analogy. It pressing in a more graphic form:

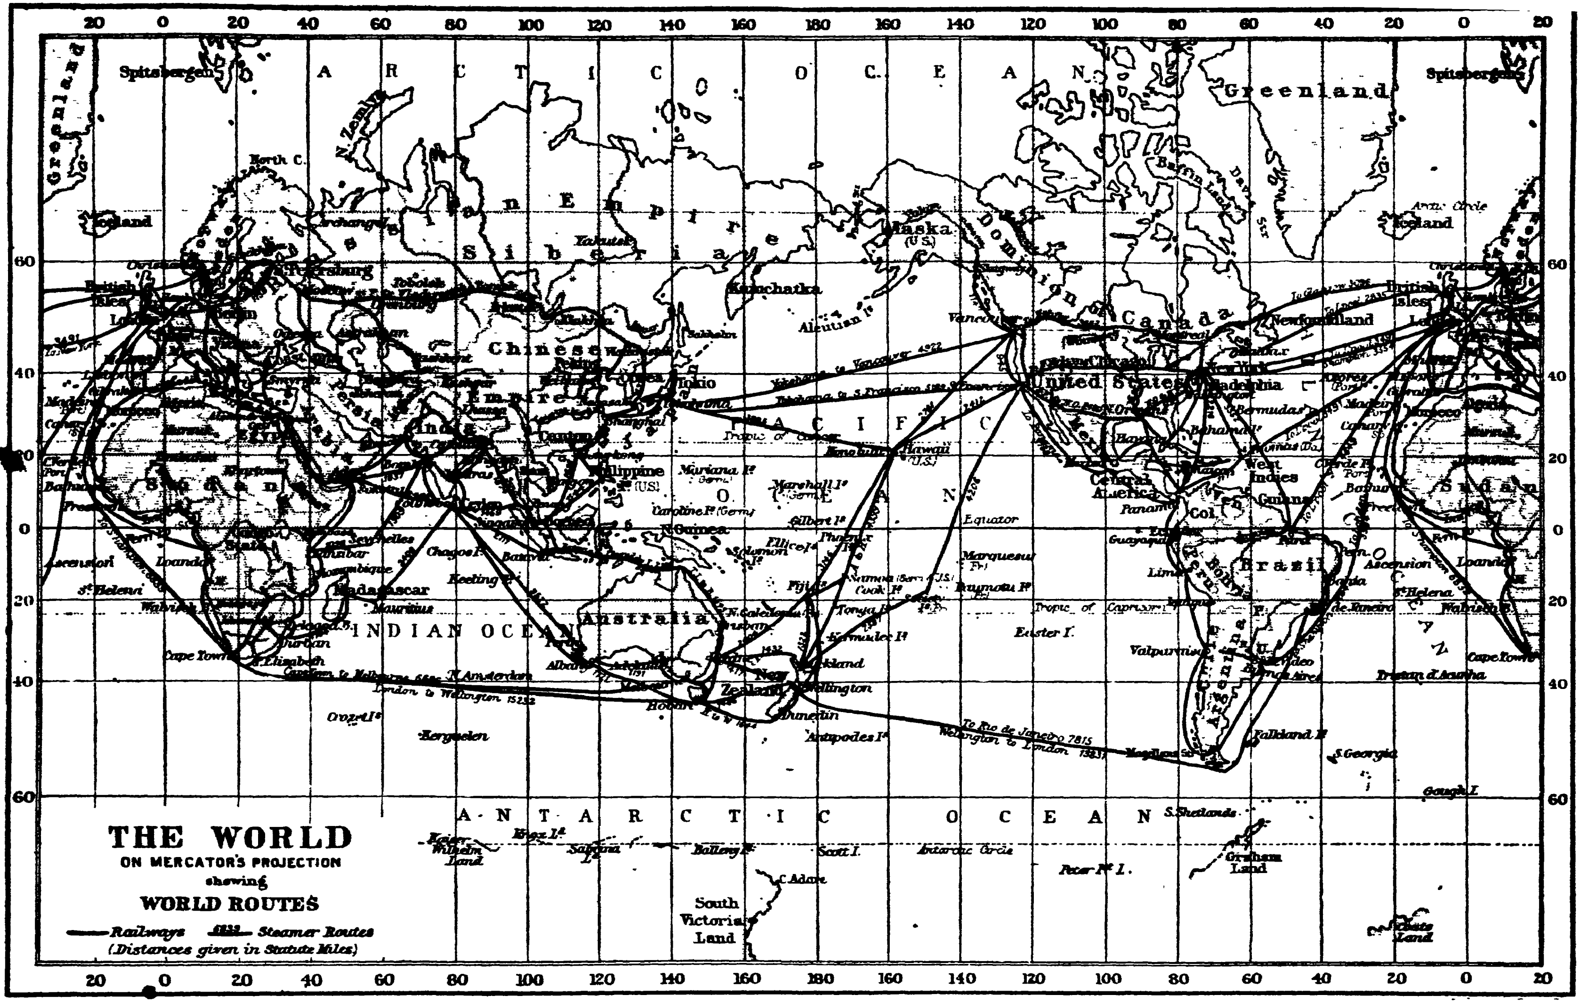
Na Selection = "Prove all things."
Va n = Individuality = Liberalism.
Ho y = "Hold fast the good" = Conser-
vatis

H ng Fast to the Good. When we mplate the worth of variation, individu originality, *creation*, we are apt, perl to appraise the contrary principle at less its true worth. Long ago—if we may allu mere party politics for a moment—the Co atives were called the "stupid party"; ar en we contemplate heredity and variation in the realm of life, we see the force of the taunt. There is something stupid about heredity; it has no imagination or initiative; it merely *holds fast*. But let us for a moment consider what would happen if there were no heredity, or if, in the organic kingdom, that force were much weaker than it is. As before, countless variations or novelties would appear in successive generations of animals and plants. The disadvantageous variations would be weeded out by natural selection, while individuals with advantageous variations would flourish. But of what avail would this be for the race if the children of such individuals did not tend to inherit their parents' advantages? Even as it is, such children tend to "revert to type," the same being true in human life, as Mr. Galton has expressed in his law of "regression towards mediocrity." The whole possibility of organic progress has depended on the incompleteness of this reversion to type, on the fact that immediate heredity is strong enough to allow advantageous variations to be perpetuated, in some degree at any rate, in the descendants of those who first displayed them. Thus life has been enabled to hold fast to that which is good; otherwise the good would die with the individual and there would be no progress.

What Would Happen Without Conservatism. And in human society the principle of conservatism is equally valuable, "stupid" though we may call it. Without it, what would happen? Obviously, we should be without any security for the permanence of the valuable. All sorts of novelties or variations would continue to spring up in all directions. We must never forget that though all progress depends upon the emergence of new characters or new ideas, yet not all new characters and new ideas are valuable; the great majority of them, unfortunately, are much worse than worthless. They are reversions or "throw-backs" to more primitive ages. A congenital idiot is a variation; the birth of such an idea as Nietzsche's, that morality is a delusion, is also a variation, and a pestilent one. It is the old brutality cropping up again. Hence, without the conservative tendencies displayed in varying degree by all of us, each successive generation would be in danger of letting go the good and suffering from the evil until natural selection destroyed it. Take, for instance, the institution of marriage. At the present time this is assailed by a host of prophets of a new social order, their new ideas being, in reality, mere "throw-backs" or reversions to the ideas of remote ages, happily long forgotten. If society had not its conservative forces (so exactly corresponding to the force of heredity in individual organisms), marriage would doubtless be abandoned—for a time. It will be maintained, however, by those conservative forces, which hold fast to that which is good.

The Better Will Prove Itself. The reader will retort, of course, that in any given case people will differ as to the goodness or badness; but, just as natural selection or the survival of the fittest, acting as umpire, upon the age-long duel between heredity and variation, has always proved itself able to prove all things, so the same is true in human society. Both sides must have a hearing, and the ultimate issue will be good. This great principle tempts the writer to discuss it in his own words; but this would not be fair to the reader, for it is fortunately possible to invoke the literature of the past on its behalf. In modern literature there is no expression of this principle to approach the second chapter of Carlyle's "Past and Present." There are five pages of this from which it is difficult to choose; but here, perhaps, is the paragraph which best expresses our principle, which, be it remembered, is nothing less than the mighty principle of toleration. Carlyle has been discussing Noble Conservatism and Ignoble Conservatism. Little could he guess—writing in 1843—that a quiet student called Darwin, of whom he had never heard, was at that moment filling his notebook with facts proving that Carlyle's words were based upon "the solid ground of nature." To our mind this is a fine example of the faith which anticipates knowledge.

The Eternal Struggle Between Right and Wrong. "For it is the right and noble alone (says Carlyle in "Past and Present") that will have victory in this struggle; the rest is wholly an obstruction, a postponement, and fearful imperilment of the victory. Towards an eternal centre of right and nobleness, and of that only, is all this confusion tending. We already know whither it is all tending; what will have victory, what will have none! The heaviest will reach the centre. The heaviest, sinking through complex, fluctuating media and vortices, has its deflexions, its obstructions—nay, at times its resiliences, its reboundings; whereupon some blockhead shall be heard jubilating, 'See, your heaviest ascends!' But at all moments it is moving centreward, fast as is convenient for it; sinking, sinking; and, by laws older than the world, old as the Maker's first plan of the world, it has to arrive there. . . . Fight on, thou brave, true heart, and falter not, through dark fortune and through bright. The cause thou



THE COMMERCIAL HIGHWAYS OF THE WORLD

NATURAL WEALTH OF NATIONS

A Survey of the Chief Natural Economic Regions of the World
and their Place in the World's Commerce. India's Trade

Group 13
COMMERCIAL
GEOGRAPHY
8

Continued from page 5308

By Dr. A. J. HERBERTSON and F. D. HERBERTSON

HAVING studied the distribution of the chief natural commodities we must now turn our attention to the economic conditions of different countries. Commerce depends on one person or people producing more than they want of something which another person or people do not produce, or produce in insufficient quantities. The excess or defect of production may be due to natural conditions or to the stage of economic development of a people. For instance, most plants are confined to a particular zone—cotton, sugar, and coffee to the warm, tropical and sub-tropical zone, oats to the cool temperate zone. Again, coal is exported from Britain to the Baltic because there is practically no coal quite near the Baltic coast; but coal is exported from Britain to China, not because there is no coal in China, but because the vast coalfields there have not yet been properly opened up. It will be useful, therefore, to consider how countries may be grouped according to their natural products, taking into consideration the economic conditions of their inhabitants.

Zones of Different Natural Products. The first broad distinctions are between the hot or tropical, the warm or sub-tropical, the cool or temperate, and the cold or Polar lands. In each belt varieties occur according as the rainfall is heavy, moderate, or very scanty. The natural vegetation gives the key to these different divisions, and the products of each type of forest, grassland, or desert are discussed in previous articles.

The Chief Trading Countries. In our own country, in most of Europe, North America, and European colonies, modern methods of cultivation, of transport and commerce have been introduced. Stock-raising, fishing and agriculture are carried on for the market, and the working of minerals and the development of manufactures are developed on a large scale. These countries may be further subdivided into two groups—those importing food and raw materials and exporting manufactured articles—such as Central and Western Europe and Eastern North America; and those largely exporting natural and cultivated products, and importing manufactured goods, such as Eastern Europe and European settlements in warm and cool temperate zones.

The Eastern Awakening. In Japan, China, and India, the soil is even more carefully cultivated than with us, but metal-working and manufacture by modern methods on a vast scale have only recently been introduced. The trade of these countries resembles that of the group last considered in that they still export natural products and import manufactures. The methods of agriculture are laborious, labour-saving machinery is little used, products are grown mainly for home use, manufactures and metal-working may be described as domestic, for the factory system has only recently been introduced. Japan is at present the most advanced of these countries, but India and China are following it.

The Poor Lands of the World. The poor lands around the Poles and the desert margins have too little natural wealth for exportation on a vast scale, but here and there, where rich mineral deposits occur, such as gold in Klondike, or where irrigation can be practised, as in Russian Central Asia, a dense and busy population is concentrated in districts usually of limited area. The lumber, etc., of the forest [pages 4657-8], and the animal wealth of the seas [page 5121] are the chief other commodities. The trade is one of export of natural products or minerals more or less worked up in exchange for manufactures.

The Rich Hot Lands. The rich grasslands of the hot belt have a denser population engaged in agriculture, pastoral pursuits, and even domestic manufacture. A considerable local trade is developed. Their exports are mainly natural products, for which manufactures are taken in exchange. They differ from the poor lands in possessing vast possibilities, and here and there, under European stimulus and supervision, are producing on a large scale—for example, bananas in the West Indies and cotton in most of the area.

The hot wet forests are much more backward. There is little agriculture or even domestic manufacture. The spontaneous products such as rubber, oil palm, coco-nuts are exported in exchange for light cloth, hardware, and firearms. In the distant future these forests may become invaluable sources of supply of vegetable foods and raw materials.

The Study of Economic Geography. The first question to ask in studying commercial geography is what are the natural conditions of a country, its vegetation, its animal products, its mineral wealth? Next come considerations of density of population—how far the country can support the people, how far routes are opened up to allow its districts to communicate with each other and with other lands. These points have already been dealt with in the general geography.

The next consideration is the commerce of the land—how far it has commodities to export, and how far it must obtain necessaries and luxuries from outside its boundaries. From the outset the student is strongly advised to make use of statistical publications. It is not necessary to remember the detailed figures, but it is important to grasp the relative importance of the different exports and imports, and to try to understand what they mean geographically.

In the following sections such statistical tables will be freely used at first, and their significance pointed out, so that the student may become familiar with the examination of such tables for the purposes of commercial geography. Later, when he is thoroughly practised in this, it will not be so necessary to print many tables, but merely to refer the student to them in such annuals as the "Statesman's Year Book," the "Daily Mail Year Book" or "Whitaker's Almanack."

It is easiest to begin with the simpler conditions of the lands last mentioned, and to end our survey with the economic activities of the complex modern states of European peoples and their descendants

THE DECORATION OF POTTERY

How Decoration is Applied to Pottery. Clay Decoration. Printing on the Biscuit. Coloured Glazes. Chromo-Lithography. Lustres

By MARK SOLON

THERE is no industry which lends itself to so many varied forms of decoration as pottery manufacture. At almost every change in the state of the clay opportunities are afforded for introducing colour and decoration. If we exclude the plastic property of the clay, which enables us to create new and decorative forms by the help of the modeller, there remain five distinct technical methods of decorating the ware. Taking these in the order in which they occur in the process of manufacture, they are: (1) colouring of bodies or clays; (2) introduction of colour on the biscuit either by printing or painting; (3) use of coloured glazes; (4) application of soft colours or enamels on the glaze; (5) metallic or lustre decoration. These methods used either singly or in combination with each other give us an endless field of decorative effects.

The Application of Colours. It is not necessary here to dwell upon the methods of the sculptor or modeller, which, although they contribute so much to the decoration of the pottery, must be considered as a separate art. We will, therefore, confine ourselves to the application and production of various colours.

These colours depend entirely on certain metals and their preparation and behaviour under different treatments. Those most commonly used are iron, cobalt, chromium, nickel, manganese, copper and antimony. The more expensive and rare metals, such as gold, silver, uranium, platinum, titanium, are used in small quantities to give certain effects.

Preparing Colours for Bodies or Clays. In preparing our colour for decoration with bodies or clays we are limited to those metals whose colouring properties will withstand the heat necessary to vitrify the clay, or, in other words, the temperature of the biscuit oven. In every case a small quantity of the suitably prepared metal or its salt is intimately mixed with the body, being introduced in the form of an extremely fine powder. The colours which can be obtained are roughly:

BLACK: Black generally results from a mixture of iron and manganese, preferably mixed with the marl or clay, which already naturally contains a quantity of oxide of iron. The colour is made richer and deeper by the addition of a small quantity of oxide of cobalt.

BLUE. Blue tints are derived from the oxide of cobalt mixed with a white body. The brighter or sky blues are obtained by calcining the cobalt with an excess of alumina before introducing into the body. Indigo tint is due to an excess of silica and the presence of zinc.

GREEN. The oxide of chrome mixed with a white body gives the foundation of all green tints. They may be made more blue by the addition of cobalt, or yellow by the introduction of iron or nickel oxide.

YELLOW. Yellow is due to the oxide of iron, and is generally produced by introducing marls which contain a quantity of the oxide. Lighter tints are sometimes made by mixing a small quantity of rhutile (titanate of iron) with the white body. This latter stain is more permanent, and will stand a higher temperature than the natural marls, which, after a certain heat, have a tendency to go grey.

BROWN. Brown is given by a mixture of chrome and iron, or the chemical combination of the two, chromate of iron, with a white body. If a natural marl containing iron be used, the tint may be obtained by the introduction of a small quantity of manganese.

RED. The dull reds are due to natural red marls in which the staining agent is iron.

Brighter tints may be obtained by mixing with a felspathic body a natural silicate of iron obtained from the South of France and known as "Grès de Thiviers," which, after calcination at a high heat, developes a bright red tint.

20. WEDGWOOD JASPER WARE

Clay Painting. All the above colours are applied to the clay piece before it becomes dry—that is, when it is sufficiently dry to withstand the brush. The painting in coloured bodies is known as *Barbottine painting*. Other decorations which might be included under this heading are the jasper ware of Wedgwood [20], in which the ornament in white or coloured clay is applied to pieces of a different-coloured ground. Moulds having been prepared, either in plaster, pottery, or hard stone, of the ornament which has to appear on the piece, impressions are taken from them in clay in the white or coloured body. The ornament is then applied to the vase, the back of the clay impression being first of all moistened with thin slip. Marble or agate ware [21], in which a striated effect of various colours in imitation of these stones is required, is produced by roughly mixing together layers of different-coloured clays before the piece is pressed.

21. "AGATE WARE" TEAPOT

Sgraffito. Sgraffito [22] is a method of decorating in two colours. A layer of white or tinted clay is laid upon a body of darker colour. The lines and background of the ornament are made by scraping away the top layer of lighter clay, revealing the darker body underneath.

Colour Applied on the Biscuit, or Underglaze. The metals used in the process of decoration in which the colour is applied on the biscuit, or underglaze, are almost the same as those in the previous method. In the case of the black, blue, green and brown, the metals are the same. However, to reduce the strength of the stain, and in some cases to develop a particular tint, the metals are first of all calcined with other ingredients. For instance, the staining power of cobalt, which produces blue tints, considerably increases by calcining it first of all with such fluxes as zinc or baryta. The brighter tints, as has already been said, are produced by calcining it with an excess, about one to twenty, of alumina. The deep browns are produced from the pure chromate of iron. The lighter and redder tints are made by introducing an excess of alumina and zinc. Olive green is due to chrome oxide alone, calcined with an excess of china clay. Blue-greens are produced by mixtures of chrome, cobalt and zinc. Where a mere flux is required to lighten the tint of any particular colour, the mixtures already referred to are reduced with such materials as flint, stone, ground biscuit, or tin ash.

22. SGRAFFITO PLAQUE

Yellows are produced by calcining the oxide of antimony with oxide of lead.

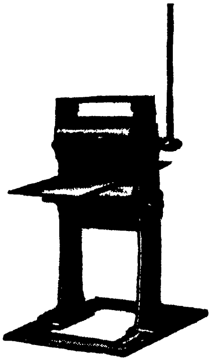
Reds do not exist in underglaze decorations, the nearest colour being a bright crimson, which is obtained by a mixture of oxide of tin, whiting, and oxide of chrome. The metallic oxides, after having been intimately mixed with their fluxes and calcined, are finely ground in water, washed, and dried.

Printing. Printing from engraved copper plate is the most common form of underglaze decoration. The colour is mixed with linseed oil, which has previously been boiled until it has thickened. The copper plate is heated and charged with the mixed colour. After the superfluous colour has been scraped from the plate, a piece of thin paper, wet with soap size, is placed upon it, and the two put through a cylindrical press [23]. On pulling the paper from the plate it brings with it the colour left in the engraved lines. This is placed carefully upon the biscuit piece face downwards, and rubbed with a flannel rubber until the pattern is fairly transferred to the piece.

The Printing Machine. In some cases, especially where large quantities of one pattern are to be printed, machines are employed [24]. The machine consists of a copper cylinder, on the surface of which the pattern is engraved. The cylinder is made to revolve slowly, colour being fed upon it from a small open trough. The superfluous colour is scraped off with a flat steel knife, the edge of which fits closely against the surface of the copper. The paper, which is wound upon a large reel, is made to pass underneath the cylinder, meeting it at the point where the engraved lines only are charged with colour. The pattern is transferred to the paper by the pressure of a roller covered with indiarubber, which is brought to bear against the copper cylinder. In this way the paper bearing the pattern is delivered from the machine in a continuous band, which is cut as required and applied to the biscuit ware in the manner already explained. The pieces are then put into the water, the paper washed off, leaving the engraved pattern on the biscuit.

The oil is then generally burnt out of the colour in small muffle kilns, and the piece dipped in the glaze and fired in the ordinary way.

When the decoration is painted, the medium mixed with the colour is either gum tragacanth or turpentine.



23. CYLINDRICAL PRINTING PRESS (W. Boulton, Ltd.)

Coloured Glazes. Coloured glazes are produced by melting or mixing with the transparent glaze the metals already referred to. The composition of the glaze, however, varies the tints given by the different metals. For instance, cobalt, if mixed with glaze in which there is a preponderance of lead, develops a deep indigo tint; if with an excess of alkalies, such as soda and potash, it develops a much brighter colour. An excess of soda in the glaze with copper develops a turquoise blue, but if lead be in excess the copper gives a green tint. Potash with manganese gives a bright violet. Yellows are formed by the introduction of iron oxide in a lead or alkaline glaze, or from the chromate of lead. Reds are formed from the mixture of tin, whiting, and chrome already referred to, together with a soft lead glaze. The glazes may be painted on the biscuit, the ornament being defined by raised lines previously formed in the clay [**25**]. Without these lines the glazes on melting would have a tendency to mix with each other where they meet, and so make any definite form of ornament impossible. If varying shades of the same colour be required, modelled surfaces may be covered with coloured glaze, lighter or darker tints being produced according to the thickness of glaze accumulating in the depressions.

Application of Soft Colours or Enamels. Up to the present our palette has been somewhat limited, owing to the heat necessary either for the firing of the clay or melting of the glaze. In the application of soft colours or enamels on the glaze, however, our range of colours is almost endless, as only a feeble heat is necessary to remelt them on the surface of the glaze, the base, or, as it is termed, the *flux*, with which metallic oxides are mixed being an extremely fusible lead or alkaline glass. In the majority of cases, a flux composed of lead, borax, and sand is used. This is melted like an ordinary frit, and afterwards ground or remelted with the colouring oxide. The metals, in order to reduce them to a fine state of division, are usually dissolved in hydrochloric acid, and then precipitated with carbonate of soda. They are afterwards well washed and dried.

The decoration is generally painted on the ware, the painter using turpentine and essence of lavender as a medium to carry the colour. Where great depth of colour is required, the pieces are fired sometimes three or four times, further tints being applied between each firing.

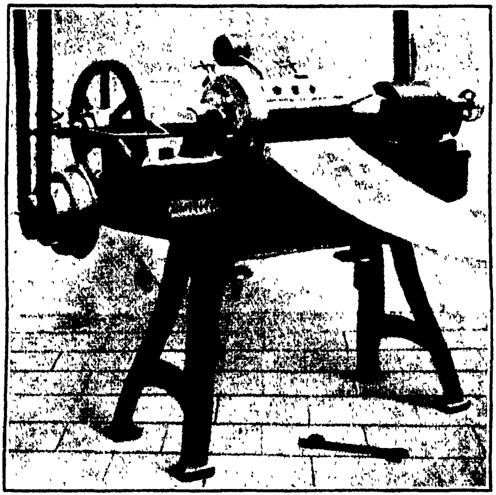
Chromo-lithography. Another form of decoration on glaze which in recent years has become extensively used is that of *chromo-lithography*. The lithographic stones are drawn and prepared in the usual way, but printed with ceramic colours on highly-varnished paper. Between the varnish and the paper is a thin layer of gum and dextrin. The lithographic transfer is placed face downwards upon the ware, which has been previously heated and sized with a preparation of resin. After being rubbed firmly to the ware the piece is put in water, when the gum and dextrin dissolve, allowing the paper to float away, and leaving the varnish and colours upon the glazed surface.

Gilding. The application of gold to the glazed surface is an important feature in the decoration of pottery. If used in combination with other processes, it is always the last stage of decoration, requiring only a very slight temperature to fix it to the glaze. The metallic gold is prepared by grinding it finely in water or turpentine, with mercury, silver, lampblack, gold alloy, and a small quantity of soft flux composed of lead, borax, and flint.

It is either pencilled, printed, or stippled with cotton-wool on to the ware. After firing, the gold, which presents a dull appearance, is scoured with fine sand and burnished with pieces of hard, highly-polished stone.

A cheaper form of gilding is by using the gold in the form of a lustre and known as "Liquid Gold." In this case the salt of the metal is intimately mixed with a large quantity of oils and resin so that the preparation contains only a small quantity of actual gold. It is brilliant after firing and so requires no scouring or burnishing.

Firing Enamel Colours. All decorations on the glaze are fired, in order to fix them to the surface of the piece, through muffle kilns. These kilns consist of fireclay boxes, generally about 3 ft. 6 in. wide, 7 ft. high, and 10 ft. long. They are built up of thin fireclay slabs, tongued and grooved on every side in such a way that the



24. PRINTING MACHINE (T. Smith & Son, Hanley)

joints between them do not allow any sulphurous or injurious fumes from the burning fuel to enter. Around the box are arranged a number of flues connected with the fire holes. The flame, on leaving the mouth, wraps round the kiln once, and sometimes twice, before escaping into the chimney. Figure **24** shows an elevation and end view of a muffle kiln, which is down-draught in principle. The pieces are placed inside the inner chamber on iron shelves built up with stout iron props of varying heights. The firing lasts from 10 to 12 hours, and the heat attained is from 900° to 1,000° C. The fireman gauges the heat of the kiln by drawing from it small pieces of pitcher, which have been coated with rose colour. This colour, which is prepared from a precipitate of gold and tin, varies accurately in tint with the increase of heat. The following table gives the degrees of heat at each variation in the tint of the colour:

25. TILES DECORATED WITH COLOURED GLAZES (Minton's, Ltd.)

Reddish brown	650° C.
Red	860° C.
Rose purple	900° C.
Violet rose	920° C.
Violet	950° C.
Pale violet	980° C.
Slight violet tint (rose colour destroyed)	1,000° C.

Lustre Decoration. Metals, such as gold, platinum, silver, uranium, copper, and iron, may be applied to the surface of the glaze, and by suitable preparation give an iridescent or lustrous effect to the glaze, after firing at a low heat. This is done by dissolving the metals in acid, and intimately mixing them with such substances as sulphur, essence of lavender, and other reducing agents, which tend during the firing to keep the metal in its metallic state. The method of preparing these lustres is one which requires great care and attention, the metallic salt being combined with reducing agents.

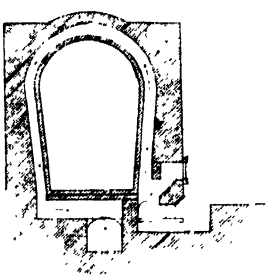
Preparing the Lustres. To prepare yellow lustre, for example, dissolve 30 parts of resin in a capsule resting in a sand bath, which has been gradually heated. When the resin is melted, add little by little 10 parts of nitrate of uranium, stirring constantly. While still stirring, add from 35 parts to 40 parts of essence of lavender. When this mixture has become thoroughly homogeneous by the constant stirring, remove the capsule from the sand bath, and add little by little a further 30 to 35 parts of essence of lavender. Allow to cool for several hours before using.

The other metals are prepared in a similar manner, the essence of lavender being sometimes replaced by turpentine or any other oil which does not precipitate the substances with which it is mixed. In the same way the resin may be replaced by sulphur or Canada balsam.

The lustre is pencilled upon the ware in thin coats, and fired in muffle kilns at a low heat.

Two Recent Productions. Some idea of the almost unlimited combinations of materials and treatment producing varied decorative effects can be formed from a short description of two recent productions, Rouge Flambé and Crystalline glazes [see Plate facing page 5233]. The former, which is essentially a "flame" red colour, is obtained by submitting a glaze containing copper and tin to reducing atmospheres—that is, during the melting of this glaze the atmosphere in the kiln is charged with unconsumed carbon generally by introducing coal gas without the necessary air to bring about its complete combustion. This change in atmosphere turns the copper from green to bright red.

Crystalline effects, which appear like clusters of opaque white or coloured stars floating in a transparent glaze, are produced by charging the glaze with an excess of some material (generally zinc) which has the property of separating out in crystalline formations as the molten glaze cools. The action is similar to that which takes place when salt has been added to excess in boiling water. While the water boils the salt appears in solution, but on cooling crystallises out on the sides of the vessel. Some of the examples shown in the plate are the productions of Messrs. Pilkington & Co., Ltd., and are the result of long research by the well-known ceramic chemist and author, Mr. William Burton. In the specimens A, E, F, H, J, L, Mr. Burton has successfully reproduced the achievements of the early Chinese potters.



26. SECTIONAL ELEVATION OF MUFFLE KILN

Arrows indicate the course of the flame

The other pieces shown on this plate, B, C, D, G, K, N, O, P, Q, R, S, are various Flambé effects by Messrs. Doulton & Co., Ltd., Burslem, and manufactured under the personal direction of Mr. Cuthbert Bailey, who has done much to make the production of Flambé a commercial success, and to systematise a process which up to recently has been greatly a matter of chance. Although the processes explained at the beginning of the article are those most generally used, the decorative potter may have recourse to an almost endless number of methods.

THINGS THAT LIVE FOR EVER

The Things that Make for Progress. Liberalism and Conservatism and their Relation to Progress. Necessity of Toleration and Freedom. Truth is Unconquerable

By Dr. C. W. SALEEBY

WE need waste no time upon those who declare that progress is a myth. The answer to this assertion in all its forms may be conveniently expressed in the one word "Darwin." The critic who does not know what that name stands for should play marbles. He may become efficient at that, but sociology is not for him. In these days we are able to go right on, and, recognising progress as the greatest of facts, to ask what are its laws and conditions. What is the meaning of the past to us?

We are the Product of the Past. In the first place, we are its products; we *are*, whereas, it only *was*; it has done its work, and from that point of view our business is not with it, but with its results. There has been far too much idle looking backwards, but if this course has taught us anything it is that we may look backwards not idly but wisely. We therefore turn deliberately backwards, but it is the future of which we think. To tell the story of the past evolution of man without any reference to what it signifies in the future is, as has well been said, to set out to tell a good story, and to leave out the point. We do not mean to leave out the point. In virtue chiefly of the work of Charles Darwin, work which we may associate with the year 1859, when he published one of the greatest books of all time, we know now that all kinds of animals and plants, small or great, highly organised, or lowly organised, owe their existence to the operation of certain factors, very easy to understand and explain. The terms we may recall are "the survival of the fittest" and "natural selection," which, however, is not a good term, for it does not explain itself.

What the Law of Progress is. Neither Darwin nor Spencer, who preceded him by a few years, nor Lamarck, nor Darwin's own grandfather, Erasmus Darwin, was the originator of the idea of organic evolution. We find it even amongst the Greeks, and we find it expressed six hundred years before Christ, by those two mighty contemporaries, Gautama, the Buddha, and Heracleitus, of Ephesus. Many people, thus, had said that organic evolution had occurred, this involving the proposition that progress had occurred, since no quibbling about the meaning of the word progress and no pessimism can explain away the difference between man and the worm. But none of Darwin's predecessors had clearly showed *why* organic evolution should have occurred, or given a practical instance of how it was occurring. Darwin established an epoch because he showed us the Law of Progress, practically illustrated in living nature. The theory, in brief, is this: that all kinds of animals and plants, high or low, large or small, tend to multiply at a very considerable rate, as we human beings do, and in fact all of the candidates for life. In the new generation some are better fitted for life in the environment in which they find themselves than are others, and as there is not room for all, there occurs a struggle for existence.

Nature is Cruel to be Kind. The struggle for existence among men, or the lower animals, or microbes, or anything you please, is easily explained. If there be room for only a proportion of the total, and if we individuals vary in our fitness, it is necessary that the fittest shall survive, whereas the weakest shall go to the wall. That, of course, credits Nature with a certain brutality. But if we come to consider what the result of the survival of the fittest is, we shall see that Nature is really cruel to be kind. Like tends to beget like; and the descendants of the unfit, whether of an oak, an ox, or a man, tend to resemble their parents in their unfitness. The descendants of unfit parents will tend to be like their parents and will also find the struggle for life hard. If, therefore, unfitness is allowed to propagate more unfitness, then life will be hard for all who are to come; while, on the other hand, fitness will tend to produce a fitter race. Hence the action of natural selection is seen to make for the increase of fitness, and therefore for the increase of happiness. Happiness and fitness go together in any sphere. Therefore the law of natural selection or the survival of the fittest must not be condemned outright as a brutal law. Terrible it undoubtedly is, according to the higher morality, which, by the greatest of paradoxes, it has itself evolved. But if we look at it for one moment, if we observe its results in the future, we see that it is unquestionably a beneficent law. It dominates the history of living things without exception.

The Good in Men Lives After Them. What we call individuality or personality among human beings is only a special case of the great fact which biologists call *variation*. It is the complement of heredity, the tendency for the offspring to vary in some character, and in some degree, from the parent seems to be a universal property of living matter. Such a variation is absolutely distinct from any change produced in the child by education or environment. Generally speaking, acquirements are not transmitted to the next generation, but variations are; and this it is which gives them such vast importance in relation to the future of society. We will not say that acquirements are of no importance except for the individual, for it is one of the cardinal facts of human life that the most valuable of acquirements, though they are not transmitted by physical heredity, are yet transmitted by *social heredity*. The learning of a Newton does not appear in his child, yet in a true sense we are all his children, and his acquirements have not died out; as has well been said "the good men *write* lives after them." So profoundly true is this that some thinkers have inclined to explain the whole of human history, and the whole difference between human society and societies of lower animals, in terms of social inheritance.

Nature does not Create, but only Selects. But for our present purpose the measure of truth in such arguments does not matter. Even granting that the acquirements of the individual may thus be made permanent and may thus be transmitted—just as his inborn variations may be transmitted, though by very different means—the great fact of the use of individuality remains. We can entirely ignore the distinction between variations and acquirements, and can still recognise that, in any case, it is the accomplishments of individuals that have made progress possible. We must never forget that natural selection does not create but merely *selects*. The truly originating or creative act is the production of variations, and the original character which is called variation in a rose is illustrated in the *individuality* of man. No biologist has yet been able to explain how it is that variation occurs, but our present business as students of sociology is simply to recognise that it does occur.

Biology teaches us that if there be no variation there can be no progress. Natural selection would still act among, for instance, the tigers—some of which, by assiduous practice, would have acquired bigger muscles than others; but the tigers thus selected would not transmit their bigger muscles to their offspring—there would be no evolution in the direction of strength.

The Things that Account for To-morrow. Apply this to man. Suppose that there were no variations in his case, and that we were all born identical. Since the environment of every man is different from that of every other—no two men have read exactly the same books—we should still come to differ from another. As the writer has said elsewhere, "Those who had made the most advantageous acquirements, such as industry or great knowledge, would tend to survive and prosper, while those who had made disadvantageous acquirements, such as laziness or the loss of sight or limbs, would be pushed to the wall. That process, of course, occurs in society at the present day to a greater or less degree, but it has only immediate and contemporary consequences. For if we recall the assertion that acquirements cannot be transmitted, we shall see that the selection of those who have made advantageous acquirements cannot benefit the next generation, since those acquirements die with their makers. The only process of natural selection which can result in progress is one which consists in the selection of favourable variations, the reason being that such are transmissible, and that the children of persons so selected will tend to inherit their parents' good fortune." Man himself is the product of the working of this law during past ages. In those ages, at any rate, acquirements had no value except for the day and the individual who possessed them. "It is inborn characters, including variations—and all inborn characters began as variations—that alone count for to-morrow."

Society is Made Up of Variations. In general we may say that *man is the least variable and the most adaptable of animals*, but we may be sure, nevertheless, that no two human individuals are absolutely identical at birth. It follows that society is not a collection or structure made up of similar units, but of units which are necessarily and constantly dissimilar. This is an ultimate biological fact which no social contrivance—and least of all any attempt to deny or ignore it—will affect. Obviously, it must have immense significance, especially if we remember that these dissimilarities tend to be inherited. How, then, must we interpret it sociologically?

Are we to welcome it or regret it? What is its relation to progress?

The answer is that through all the ages variations have constituted the raw material of progress. Unfit variations have rapidly disappeared; valuable variations, making their possessors fit, have enabled them to survive and multiply and to inherit the earth. If the value of variation be true of the lower animals, it is truer still of man; and this for several reasons. In the first place, since man is the least variable of animals, variations are rarer and have the worth of rarity. Far more important is the second consideration, that variation assumes a new form in the case of man—a higher form having a proportionately higher worth.

Genius is not Born to Die. When the biologists teach us that man is the least variable of animals, we should remember that they are speaking only of physical variation. When we ascend from the physical to the psychical plane we find that the dictum of the biologists is no longer applicable. Man is now the most variable of animals, or rather of spiritual beings; and it is because his variations are on this exalted plane that they are of such worth. Take Shakespeare, for instance; his individuality, personality, or genius was a case of psychical variation of great magnitude. A physical variation of similar magnitude would have been the possession, let us say, of half a dozen arms or hands, the worth of which would have been nothing at all, but the worth of Shakespeare's psychical variations was immeasurable. As Charles Reade said of Erasmus, in closing his greatest novel, "The words of a genius so high as his are not born to die: their immediate work upon mankind fulfilled, they may seem to lie torpid, but at each fresh shower of intelligence Time pours upon their students they prove their immortal race; they revive; they spring from the dust of great libraries; they bud, they flower, they fruit, they seed, from generation to generation, and from age to age."

The World's Gain Through Books. And there is yet a third reason why human variation, which is psychical variation, is of such great worth. It is because of the possibility of social as distinguished from physical inheritance. A useful variation in the case of one of the lower animals is worth nothing to the race unless that animal have children which will inherit and transmit it. Now Kant and Herbert Spencer were bachelors; the psychical variation which expressed itself in their genius was not transmitted by physical inheritance—which, in any case, is terribly uncertain in matters of genius. Yet, society would have lost immeasurably without those conditions of liberty which, imperfect though they were, at any rate permitted them to say their say—to which men will listen to the end of time. This point, that psychical variation in man is of value because it can be transmitted to subsequent generations by means of books, is one of the utmost importance.

And now surely we see that if individuality or variation has been the first condition of all progress in the past, of all the base degrees by which we did ascend, individuality, or psychical variation in the case of man, is in even greater measure the first and essential condition of all human progress. The law of progress is this: *that everything which is new and true and good shall be given a hearing.* This doctrine, which the writer has endeavoured to base upon the facts of biology, will immediately introduce us to the great conception of liberty.

How Truth Begins to Grow. The law of organic progress, as demonstrated to us by the study of organic evolution, constitutes the immovable natural basis for the intuitive conviction of democracy that there should be a potential field-marshal's *bâton* in every soldier's knapsack. Furthermore, as the writer has said elsewhere, "we should recognise that the greatest present and future happiness is served by the freest and fullest possible exploitation of every kind of ability—provided, of course, that it be not exploited in anti-social acts. In permitting the superior to benefit by their superiority, we benefit ourselves and our descendants. Worth of any kind is always worth something to others than its possessor. The history of all progress, from the amœba up to man, is the history of the establishment and accomplishment of novelty, variations, individuality—all difficulties notwithstanding. In all ages collective devices, academies, royal societies, have stood for the repression of individuality. In the moral, philosophic, and religious history of the world the same has been true. Every truth starts as a heresy, and the supreme individualities, the supreme prophets, the founders of religions, the noblest of the noble dead, those to whom we owe almost everything that we rightly prize, have ever been poisoned, or crucified, or stoned, or mocked, or spat upon, and invariably by collective forces. In a sense, at least, Carlyle was right when he declared that "universal history—the history of what man has accomplished in this world—is at bottom the history of the great men who have worked here." But the rule is that there arises some collective apparatus, declaring itself to possess the spirit of its founder, and the necessary foe of all such new individualities as that which gave it its own birth.

Committees are not Productive. As the intelligence of man attains greater heights, and as the principle of the worth of the individual is seen to be sanctioned by biology and human history alike, we may hope that genius, individuality, worthy variation, will no longer have to fight the mediocre majority, but will ever receive a patient hearing. It cannot for ever remain true that a "prophet is not without honour save in his own country." The history of progress, physical, moral, artistic, philosophic, is a history of the ultimate triumph of individuality. "Universal history," as Carlyle called it, might indeed be written as a controversial treatise in favour of the worth of the individual. No crowd or committee ever produced a great work of art, or generated a new energy, or conceived a new truth—but individuals ever and always. For the moment we may afford to ignore the questions of the conditions which produce the individual. It is a profoundly important question, but our immediate business is to recognise that, when somehow he is produced, he is of supreme worth to society. We in this country are already prepared, by long familiarity with two names, for the recognition of the two great complementary forces which act in any society. These are the forces of conservatism and liberalism. Certainly, most sociologists are unable to discover any recognition of first principles by the political parties which to-day take to themselves these great names; here, then, we speak not of actual party politics, but of the fundamental sociological truths which our two great political parties would represent in a wiser world.

The Great Parties in the State. The conditions of organic evolution, as distinguished from its factors, are two—*heredity* and *variation*. We have already insisted at length upon the fact that without variation there could be no progress in the organic kingdom, just as without its expression, individuality, there could be no progress in the kingdom of man. It is now our business to emphasise more clearly than has yet been done the value of the complementary fact of heredity. Heredity is the principle of conservatism or conservation. Its highest business and duty is to *hold fast to that which is good.* The reader will remember the earlier part of this famous phrase—"Prove all things." What is it in the case of individual organisms that proves all things? Plainly it is none other than the principle of natural selection. Again, if there were no variation, here would be nothing to “prove,” nothing o “select.” The more one contemplates this great saying of St. Augustine's, and the more that, in the light of the idea of the social organism, we compare social forces with those that act amongst individual organisms, the more impressed must we become with the beauty of the analogy. It is worth expressing in a more graphic form:

tural Selection = “Prove all things.”
riation = Individuality = Liberalism.
redity = “Hold fast the good” = Conser-
m.

Holding Fast to the Good. When contemplate the worth of variation, indi- iality, originality, *creation*, we are apt, haps, to appraise the contrary principle at than its true worth. Long ago—if we may de to mere party politics for a moment—the nservatives were called the “stupid party”; d when we contemplate heredity and variation the realm of life, we see the force of the taunt. There is something stupid about heredity; it has no imagination or initiative; it merely *holds fast.* But let us for a moment consider what would happen if there were no heredity, or if, in the organic kingdom, that force were much weaker than it is. As before, countless variations or novelties would appear in successive generations of animals and plants. The disadvantageous variations would be weeded out by natural selection, while individuals with advantageous variations would flourish. But of what avail would this be for the race if the children of such individuals did not tend to inherit their parents' advantages? Even as it is, such children tend to “revert to type,” the same being true in human life, as Mr. Galton has ressed in his law of “regression towards liocrity.” The whole possibility of organic gress has depended on the incompleteness of reversion to type, on the fact that immediate dity is strong enough to allow advantageous ations to be perpetuated, in some degree at rate, in the descendants of those who first layed them. Thus life has been enabled to l fast to that which is good; otherwise the d would die with the individual and there ld be no progress.

hat Would Happen Without Con- vatism. And in human society the principle onservatism is equally valuable, “stupid” gh we may call it. Without it, what would pen? Obviously, we should be without any rity for the permanence of the valuable. All s of novelties or variations would continue to ng up in all directions. We must never et that though all progress depends upon the rgence of new characters or new ideas, yet all new characters and new ideas are valu- ; the great majority of them, unfortunately, are much worse than worthless. They are reversions or “throw-backs” to more primitive ages. A congenital idiot is a variation; the birth of such an idea as Nietzsche's, that morality is a delusion, is also a variation, and a pestilent ne. It is the old brutality cropping up again. Hence, without the conservative tendencies displayed in varying degree by all of us, each successive generation would be in danger of letting go the good and suffering from the evil until natural selection destroyed it. Take, for instance, the institution of marriage. At the present time this is assailed by a host of prophets of a new social order, their new ideas being, in reality, mere “throw-backs” or reversions to the ideas of remote ages, happily long forgotten. If society had not its conservative forces (so exactly corresponding to the force of heredity in individual organisms), marriage would doubtless be abandoned—for a time. It will be maintained, however, by those conservative forces, which hold fast to that which is good.

The Better Will Prove Itself. The reader will retort, of course, that in any given case people will differ as to the goodness or badness; but, just as natural selection or the survival of the fittest, acting as umpire, upon the age-long duel between heredity and variation, has always proved itself able to prove all things, so the same is true in human society. Both sides must have a hearing, and the ultimate issue will be good. This great principle tempts the writer to discuss it in his own words; but this would not be fair to the reader, for it is fortunately possible to invoke the literature of the past on its behalf. In modern literature there is no expression of this principle to approach the second chapter of Carlyle's “Past and Present.” There are five pages of this from which it is difficult to choose; but here, perhaps, is the paragraph which best expresses our principle, which, be it remembered, is nothing less than the mighty principle of toleration. Carlyle has been discussing Noble Conservatism and Ignoble Conservatism. Little could he guess—writing in 1843—that a quiet student called Darwin, of whom he had never heard, was at that moment filling his notebook with facts proving that Carlyle's words were based upon “the solid ground of nature.” To our mind this is a fine example of the faith which anticipates knowledge.

The Eternal Struggle Between Right and Wrong. “For it is the right and noble alone (says Carlyle in “Past and Present”) that will have victory in this struggle; the rest is wholly an obstruction, a postponement, and fearful imperilment of the victory. Towards an eternal centre of right and nobleness, and of that only, is all this confusion tending. We already know whither it is all tending; what will have victory, what will have none! The heaviest will reach the centre. The heaviest, sinking through complex, fluctuating media and vortices, has its deflexions, its obstructions—nay, at times its resiliences, its reboundings; whereupon some blockhead shall be heard jubilating, ‘See, your heaviest ascends!’ But at all moments it is moving centreward, fast as is convenient for it; sinking, sinking; and, by laws older than the world, old as the Maker's first plan of the world, it has to arrive there. . . . Fight on, thou brave, true heart, and falter not, through dark fortune and through bright. The cause thou fightest for, as far as it be true, no farther, yet precisely so far, is very sure of victory. The falsehood alone of it will be conquered, will be abolished, as it ought to be; but the truth of it is part of Nature's own laws, co-operates with the world's eternal tendencies, and cannot be conquered. . . Seek through this universe, if with other than owl's eyes, thou wilt find nothing nourished there, nothing kept in life, but what has right to nourishment and life. The rest, look at it with other than owl's eyes, is not living; is all dying, all as good as dead! Justice was ordained from the foundations of the world, and will last with the world, and longer."

The First Preacher of Toleration. The extraordinary parallelism between this chapter and the principles of Spencer and Darwin is worth pointing out, if only as a contribution to the history of thought. We of this generation may learn from it, too, for Carlyle despised the evolutionists, and called Spencer "the most immeasurable ass in Christendom." Many of them, also, would have liked to suppress Carlyle, but, thanks to the principle of toleration and individuality, both expressions of the truth were permitted to be heard—and *we* benefit proportionately. It is a great lesson.

If now we turn to the fifth chapter of the Acts of the Apostles we find what Sir Leslie Stephen considered to be the first expression on record of the principle of toleration—this great principle, the worth of which, by her recognition both of heredity and variation, Nature teaches us, and yet which in the twentieth century we are only slowly beginning to learn. When the crowd, with its "ignoble conservatism," "took counsel to slay the Apostles," Gamaliel stood up in the council and said: "Refrain from these men, and let them alone, for if this counsel or this work be of men, it will come to nought; but if it be of God, ye cannot overthrow it, lest haply ye be found even to fight against God."

Truth is Able to Look after Itself. Here, then, is the great lesson for the partisan. We must hear all sides, strong in the faith that truth is great and will prevail. We may be absolutely convinced that we are right and that our opponents are immeasurably wrong; but let them have their say. Truth will prevail, and never more certainly than by the mutual slaughter of opposite extremes.

Let us just consider the two methods by which we may seek to establish what we believe. The one method is, in its extreme form, to assert our belief, to compel everyone to avow it, and to destroy every statement of any other opinion. This is the legal method, and it has been adopted in all ages. It was on this principle that the Church burnt Bruno and silenced Galileo; it was on this principle that the Athenians poisoned Socrates. This is the "ignoble conservatism," which not only disbelieves in variation or liberalism, but disbelieves that there are any laws of Nature which will ensure that evil cannot prevail. If you have no such faith, evidently it is your duty, whenever you can, to burn, poison, impriso gag, vilify, or otherwise silence all who disagre with you. Truth is not safe, you believe, unless these methods be adopted. Nature is not on her side, and Truth's only chance is that no one be ever allowed to say anything that is false. Hal the evils of human history—religious persecution wars of religion, judicial murders of the gre good and divine, have been based upo principle—that *the only chance for the survi the truth consists in the employment of brute*

Nature is on the Side of Truth. other method by which we may seek to esta the truth is by the principle of freedom of sp The idea underlying it is the essentially noble religious idea that Nature is on the side of tr It is the idea of the survival-value of truth. society which believes in this principle there be room both for Conservative and Liberal ne papers: and the Liberals, for instance, will think that all would be well if only the Conser tive Press could be suppressed. In such a society the men of science will not seek to silence the dreamers and the prophets, nor the dreamers and prophets to silence the men of science. What need to fear the false if the false has but to show its face to be ground into the dust? Nor dare we forget that if history teaches us anything, it is that brute force employed on behalf of what was believed to be true has only too often been prostituted to the service of the false—with vengeance sure.

Freedom of speech, then, freedom of thought, and "the liberty of prophesying"—these are the natural and warrantable means, in strict accordance with Nature's own methods, by which progress may be attained. It is very difficult indeed to live up to these principles. Let us suppose that you are a conscientious and humane physiologist: would you not be very much tempted, if you had the power, simply to suppress all anti-vivisectionists? And yet you would be wrong. The right way in which to combat false ideas is by true ideas, and not by brute force.

The Battle of Ideas. But the great principle of selection and survival has undergone a transmutation in our own times and a transfiguration from the physical to the psychical. We live not by our muscles so much nowadays as by ideas, and that society is healthy and prosperous where the battle of ideas is most strenuously and fairly and openly fought: where the only argument is argument and not brute force; where everything that can make itself articulate is heard, and where, therefore, if it be false, it is the soonest forgotten. Just as heredity and variation stood for the complementary forces of progress on the plane of the physical, so conservatism and liberalism, in society, in politics, in science and religion and art, are the complementary forces of progress on the plane of the spiritual.

The struggle now is not between thew and thew but between thought and thought. If we desire to ascertain the best conditions of that struggle we must turn again to the supreme adjudicator Nature.

Continued from page 5244

By D. H. KENNEDY

The Wheatstone Automatic System. It was stated on page 4385 that three instruments—namely, the perforator, the transmitter, and the receiver are necessary for this system. For convenience, however, double-current sounder system apparatus is added to each end of the line, to enable the telegraphists to communicate corrections and acknowledgments. A rheostat and condenser are also necessary if speeds above 300 words per minute are required.

The Perforator. The mechanism of this instrument [8] is arranged so that the keys operate five punches, which are arranged as follows:

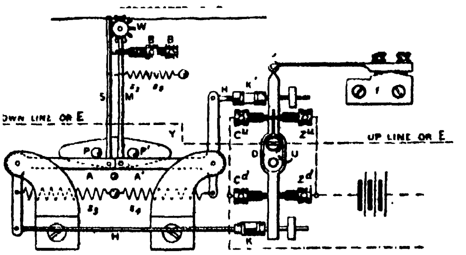
(1) o
(2) o o (4)
(3) o o (5)

Depressing the left key (dot) actuates 1, 2, 3; depressing the right key punches 1, 2, 4, and 5; and depressing the centre key actuates 2 only. Thus we punch letter A, followed by a space as in **9** [page 4386].

The centre row of perforations forms the rack by means of which the paper is propelled through the transmitter. The upper and lower perforations control the current-sending mechanism.

The machine is adjusted to punch 120 spaces in exactly twelve inches. The gauge is tested by punching the word "telegraph" three times, with the usual double space between each. From the ginning of the first "t" to the end of the last "h" ere are 121 spaces, and the distance, centre to ntre, between the first and 121st should be prescely one foot.

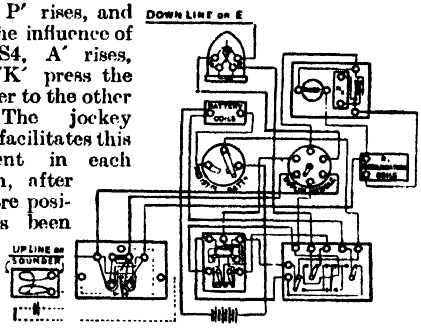
ices, such as the London News Division, it is cessary to prepare simultaneously several slips. or this purpose the assistance of pneumatic power invoked. Figure **65** shows such an arrangement. he operation of the three white keys controls e air supply to two sets of plungers, which e the place of the operator's mallets. As plenty of power is available, double or treble rolled slips may be used, and it is possible to arrange for as many as eight slips at one operation. A higher speed is made possible, as the keys are so light as to render the use of mallets unnecessary.



63. TRANSMITTER MECHANISM

The Transmitter. The transmitter is shown on the right in **66**. Under the control of the perforated paper it performs the work of a double-current key, producing signals of unvarying excellence, and at a speed ten to twenty times that of its human rival. The controlling mechanism is shown in **63**. DU is the compound reversing lever, the front portion, U, being insulated from the rear portion, D. They are connected to the lines as shown, and it will be seen that the contacts are placed so that when the top of the lever is deflected to the left a positive current goes to the "up" line, and a negative to the "down."

When the transmitter is running free of slip, its clockwork rotates the wheel W, and also causes the lever, PP′, to rock on its centre. Now when P presses down A, H and K are moved to the left. Simultaneously P′ rises, and under the influence of spring S4, A′ rises, and H′K′ press the lever over to the other side. The jockey wheel J facilitates this movement in each direction, after the centre position has been passed. In later forms a *magnetic bias* has been introduced i be seen that whe alternating currents are sent to line, which produce dots, or, as they are called, *reversals*, on the distant receiver.



64. CONNECTIONS OF WHEATSTONE DUPLEX SET

Now we must consider what takes place when the slip is inserted. An important point to note is that the rod S is not parallel with, but, as shown, in *front* of, the rod M. Imagine that we insert the slip [**9**, page 4386]. It reaches M first, and prevents it from rising; S rises and at the next oscillation of PP′ it also is held down, and the points of both slide along, waiting for a hole in the paper. Meantime, in consequence of the fact that S rose *last*, a spacing current is being sent to line. At length M passes up through the first upper hole of the letter C, and is immediately withdrawn again; this, however, causes a marking current to be sent, which continues until S passes up through the first bottom hole in the paper, and causes a spacing effect. Immediately afterwards M passes through the upper hole of the dot, and is withdrawn. This begins a marking signal for the dot, which is immediately terminated by the rod S passing through the bottom hole, and so on, signal by signal. At the end of the word the rod S is the last to come into action, and so the spacing current persists until the paper runs out, when the reversals begin again. Six hundred words per minute is the maximum speed, and it is interesting to note that at this speed a dot signal persists for $\frac{1}{240}$th part of a second. Such high speed is, however, seldom called for, and 200 words per minute is general.

As indicated in the connection diagram [64], the starting lever of the transmitter, visible on the left, also actuates a switch which diverts the battery and line connections from the key to the transmitter.

The clockwork is impelled by a heavy weight, which is wound up by a handle which projects from the front. The running speed is regulated by the lever at the top, behind the case. It can be clamped in any desired position. The curved pins in front of the transmitter are used to retain the ends of used slips for a short time in case a retransmission is required.

The Receiver. The receiver, visible on the left in 66, is a combination of the principles already described in the P. O. S. Relay, and the Inkwriter. By means of clockwork a thin blue paper slip is drawn over a roller, and the same mechanism rotates an inking wheel in a direction opposite to that of the paper. An electromagnet, built on the same lines as a P. O. S. Relay, and connected directly in the line circuit, controls the wheel. The marking disc does not, as in the inkwriter, rotate in the inkwell. It takes its supply from the upper edge of a larger wheel, the lower part of which rotates in the ink. What corresponds to the tongue of the relay directly controls the axle of the marking disc, and so reproduces signals. In addition, however, a local contact is provided at the bottom of the electromagnet, to which the sounder is connected.

65. PNEUMATIC PERFORATOR

The clockwork of the receiver in 66 is impelled by a spring. The speed regulator is in the same position as on the transmitter. The adjustment of the electromagnet armature is made by means of the milled nut which projects above the case.

Two slip drawers can be seen in the base. Each of these contains a rotary slip carrier. Two boxes are provided to prevent the possibility of a despatch being lost owing to the slip running out. To this end also each roll of slip has near its inner end a few convolutions of red slip. As soon as this appears, opportunity is taken to slip in the beginning of a roll from the second box.

66. AUTOMATIC WHEATSTONE SET

For high-speed working with spring-type receiver

Wheatstone Duplex. The Wheatstone system can be duplexed, and 67 shows a set arranged for working in both directions. The speed attainable in each direction is about two-thirds of that possible under simplex conditions. The receiver shown in this set is provided with a weight motor train. The bell fixed on the right side gives indication when the weight requires rewinding.

A connection diagram is given in 64. To facilitate balancing for duplex working, a two-way switch is provided so that the battery power may be cut off the line and an equivalent resistance substituted.

Keyboard Perforators. Attempts are now being made by inventors to reduce still further the labour and to lessen the time consumed in preparing the perforated slips. Figure 68 depicts the Kotyra system, which is at present (1907) undergoing experimental trial at St. Martin's le Grand.

On the right there is a three-tier pneumatic perforator which can prepare simultaneously twelve slips. Its plungers are controlled from the *Kotyra* keyboard. The little electric motor on the left rotates a cylinder. This is provided on its surface with teeth, which the under-surface of any key engag [illegible] pression. The key is drawn backwards away from the operator and makes a suitable series of contacts, closing the circuits of three electromagnets, which, in turn, control the pneumatic perforators. Having performed its duty, the key is released by a trigger action, and returned to its place by means of a special spring. The operator must wait for this release before depressing another key.

It has been proposed to apply the Kotyra keyboard direct to the line, so that, instead of forming the Morse signals by hand, the operator would press the Kotyra keys, and the feasibility of this method has actually been demonstrated, the services of an operator who, owing to an attack of telegraphists' cramp, was unable to send in the ordinary way being thus utilised. It will be noticed that the system resembles closely that which was invented by Professor Morse, and which preceded the invention of the Sounder System.

Yetman Transmitting Typewriter. Another competitor in the same field is the Yetman. Two forms are shown in 69; that on the right is used for sending in the way suggested for the Kotyra. The instrument on the left combines, in addition to the electrical sending portion, the functions of a typewriter, so that it produces a record of the letters sent.

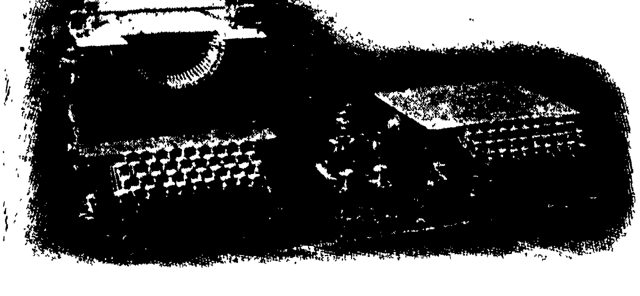
Creed Perforator. A more ambitious arrangement is that shown in 70 and known as the Creed Keyboard Perforator. The mechanism of an ordinary typewriter has been modified so that on depressing a key it makes the appropriate selection from a set of twenty punches, and produces the perforated letter at one stroke. A speed of sixty words per minute can be maintained. As in the cases already mentioned, pneumatic power at a pressure of 10 lb. per square inch is used, and four slips can be produced simultaneously.

Type Printing Telegraphs. It is probable that no department of telegraphy has been the subject of more patent specifications than this one, although the successful systems are few indeed. Five interesting systems have been chosen for illustration.

67. DUPLEX AUTOMATIC WHEATSTONE SET

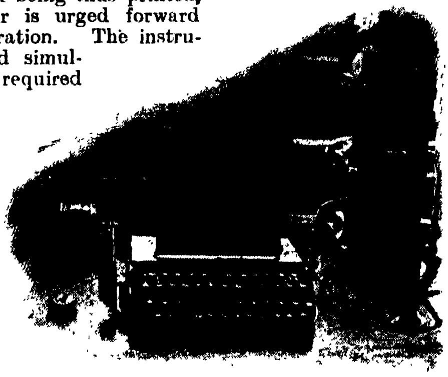
The Steljes Type Printing Telegraph. This is a system based on the Wheatstone A B C, the A B C indicator being displaced by a Steljes recorder, which prints the signals sent by a Wheatstone communicator in Roman letters on a paper tape [71]. The received alternating currents pass through two electromagnets joined in series—one is polarised, the other non-polarised. The armature of the polarised relay oscillates, and in doing so allows an escapement wheel to turn forward—one tooth for each letter current. On the same axle is the letter wheel, which can be seen just above the paper, and has above it an inking-wheel brush. The same series of currents in passing through the non-polarised relay attract and hold its armature until the currents cease. The armature then drops and allows a printing-lever to jerk the paper up against the letter wheel, the required letter being thus printed, and simultaneously the paper is urged forward in readiness for the next operation. The instruments at both ends record simultaneously, and no attendant is required at the receiving end. By an ingenious arrangement three revolutions of the communicator needle secure that the recorder shall start from zero. Had the invention of this instrument preceded the telephone it would have had an enormous sale. It still finds a large field for its use—superimposed on telephone lines—in confirming messages transmitted orally.

The Hughes Printing Instrument. This has so far been the most successful system. Some thousands of instruments are in use on the Continent and on the cables between this country and the Continent. Figure **72** shows a set in use between London and Rome. The sending is done by means of a keyboard resembling that of a piano. At the receiving end the message issues from the instrument printed in Roman characters on a tape, which the operator breaks off into suitable lengths and pastes on a form, in which state it goes out for delivery. When a message is sent, both receivers are actuated so that mistakes are at once visible to the sender.



69. YETMAN TRANSMITTING TYPEWRITER

By means of a most admirable mechanism it is arranged that the sending contact-makers and the receiving printing wheels at both stations shall revolve continuously and synchronously, so that at any given instant all four are opposite the same letter. If, then, a key is depressed at either end a contact is made, and simultaneously the letter is printed at both stations. The synchronism is regulated by a vibrating spring. Only one current is sent for each signal. It has the effect of releasing an armature from an electromagnet, and this immediately sets in motion a train of mechanism which prints the letter, moves the paper forward, and replaces the armature in readiness for another signal. Synchronism is maintained by means of a correcting cam, which is forced between the teeth of a star-wheel fitted on the printing axle, and adjusts it each time a letter is printed.



68. KOTYRA KEYBOARD PERFORATOR

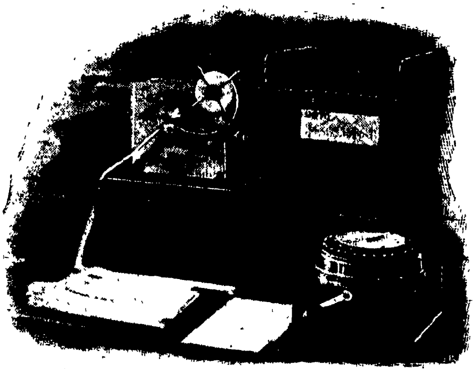
It is instructive to contrast the Steljes system with the Hughes system. In the former a succession of currents urges forward the printing wheel and maintains the necessary synchronism, while their cessation produces the printing effect. In the Hughes the synchronism is arranged for mechanically. A *no-current* time interval takes the place of the succession of currents just referred to, and its termination is marked by the single current.

The Hughes type-wheel is *not* stopped, or even retarded during the printing process. In both systems it will be noted that only a limited number of letters per revolution can be manipulated—the average number is two—and that this determines the speed. In the case of the Hughes, however, the rate of rotation is high, and the average speed of working is about forty words per minute.

The Hughes instrument can be worked on a duplex system. The differential method is employed in the same way as has already been described in the case of the single-current sounder. Figure 75 illustrates a duplex set which is worked between London and Berlin. Of course, one of the instruments is used continuously for sending and the other for receiving. Between the two Hughes sets can be seen the single-current key and switches which enable Morse signals to be used during the balancing process.

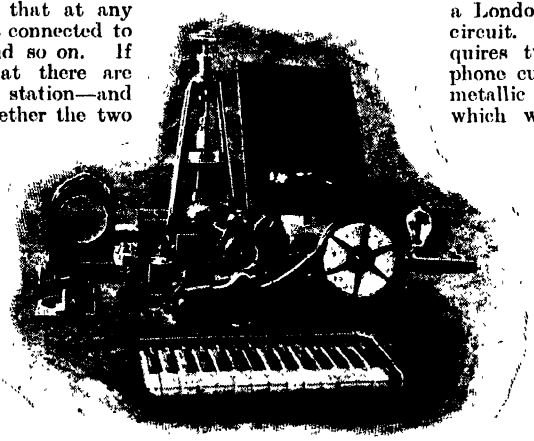
70. CREED KEYBOARD PERFORATOR

The Baudot System. In the Baudot system [73] signals are received in Roman characters on a printed tape exactly as in the Hughes system, but the means by which this is achieved are entirely different. M. Emile Baudot originated a system in which the alphabet is arranged so that every letter requires the same number of signal units, and the aggregate number of signals is the smallest possible. The signals are permutations of five *space* and *current* units, and to produce them the operator is provided with a sending instrument having five keys similar in appearance to those of the pneumatic perforator. Corresponding with the five sending keys there are in the receiving instrument five electromagnets, which repeat the signals given by the keys, and by means of a very beautiful mechanism actuate the printing wheel so as to produce the required Roman characters.



71. STEIJES TYPE PRINTING SET

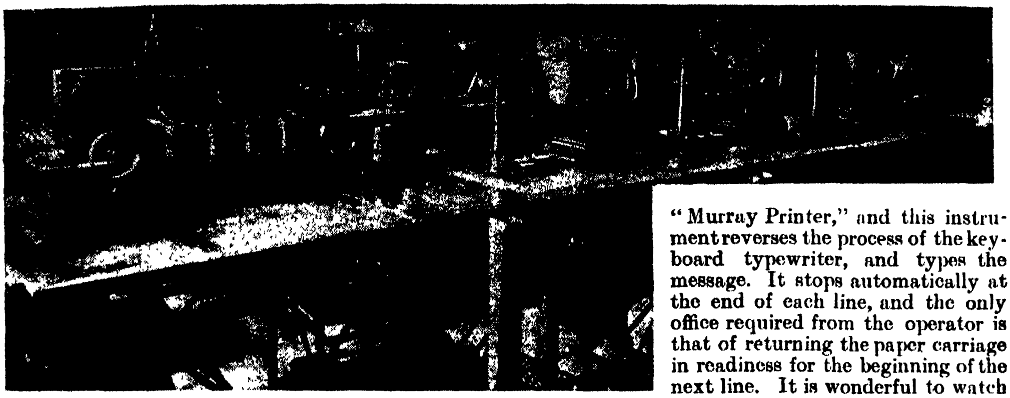
It would seem that this arrangement would necessitate five wires between the two stations, but this is obviated by having at each end a rotary distributor arranged so that at any given instant No. 1 key is connected to No. 1 electromagnet, and so on. If the reader imagines that there are two clocks—one at each station—and that the line connects together the two minute hands, then, if the clocks keep accurate time, and we suppose that No. 1 key is connected to 12 o'clock at one end and No. 1 electromagnet to 12 o'clock at the other end, it is clear that if we arrange for electrical contact between the figure and the pointer the instruments will be in connection once every hour. This principle of rotary synchronism is used, in the Baudot system, but instead of one revolution per hour we have 180 revolutions per minute, and instead of arranging for one instrument with five keys, it is found possible to arrange for four instruments each having five keys, so that four operators are required at each end, and they can work independently as if they had separate circuits. There is, however, one limitation. The rotary distributor connects a given instrument through to the corresponding receiving set three times per second, and the signals between those sets must be sent during the connected interval or they will be lost. The operators are, therefore, trained to send exactly three signals per second, and to enable them to make their signals at the correct instant "watch receiver" telephones are provided which give a click each time that the distributor connects up the instrument to the line. It is found that in course of time operators become so accustomed to this "cadence," as it is called, that they can work with perfect accuracy even without the aid of the telephone signal.



72. HUGHES PRINTER, SIMPLEX SET

The illustration [73] gives a view of one of the three sets which work between London and Paris. On the left can be seen the rotary distributor, and, beginning from the centre, the four telephones on projecting brackets are visible, and beside them the sending keys and receiving instruments. The heavy weights visible beneath the table are provided with electric motors which come into circuit automatically and wind up when required.

Baudot Superimposed on Telephone Trunk. A still more interesting fact in connection with two of the London-Paris Baudot sets is that each of them is superimposed on a London-Paris telephone trunk circuit. A telephone circuit requires two wires, and the telephone currents pass around the metallic loop. By a method which will be described in the telephone section, the two wires in parallel are utilised to carry the Baudot signals in such a way that there is no interference. When we consider that two small wires can in this way be used simultaneously for one telephonic conversation and four telegraph messages, we realise that if electricians have still to acknowledge their ignorance of the nature of electricity, they have at least made substantial progress in the knowledge of how to control and use this mysterious and wonderful force.



73. BAUDOT FOUR-WAY SET

The Murray Type-printing Telegraph. One of the latest developments in type printing by telegraph is the Murray system, which for the last three years has been on experimental trial by the Post Office Department, in regular service, between London and Edinburgh and London and Dublin. The Murray may be said to bear the same relation to the Baudot as the Wheatstone set syste TheBaudot alphabet is used, but, as in the case of the Wheatstone, though these are largely made automatic. The messages are first produced on a punched slip by means of a keyboard perforator. The slip is then passed through a transmitter, somewhat similar in principal to the Wheatstone. The receiving instrument, however, also produces a perforated tape similar to that which has been used at the sending end. The perforated tape is then passed through the instrument known as the "Murray Printer," and this instrument reverses the process of the keyboard typewriter, and types the message. It stops automatically at the end of each line, and the only office required from the operator is that of returning the paper carriage in readiness for the beginning of the next line. It is wonderful to watch one of these instruments typing as if with the aid of an invisible operator at the marvellous rate of 120 words per minute.

Mr. Murray has also conceived the idea of applying his instrument to operate a Linotype keyboard, so that it is quite conceivable that on some future date one of our great London dailies may have its type set up by an operator sitting, say, in Paris.

The Murray Creed System. The two instruments shown in **74** are: on the right the Creed receiving perforator, and on the left the Murray-Creed type printer. These instruments produce those described in the case of the Murray, but the alphabet used is the same as in the ordin- is therefore possible to substitute the Murray-Creed receiving perforator for the Wheatstone receiver on any ordinary Wheatstone circuit. The tape which issues from the instrument is the ordinary Wheatstone perforated tape, and it can be used either in the Murray-Creed receiving type printer, or in the ordinary Wheatstone transmitter for retransmission on other lines.

THE EVOLUTION OF SWEDEN

The First Years of Sweden's Independence. Gustavus Adolphus and Wallenstein. The Decline of Spain's Greatness. Discovery of Brazil

By JUSTIN McCARTHY

THE NORTHERN KINGDOMS

The Union of Calmar, in 1397, brought Denmark, Sweden, and Norway into one state under Eric XIII., each kingdom retaining its own laws and customs, and its own legislative assembly. Sweden soon withdrew from the Union and became an independent state, and, despite the actual terms of the Union, Denmark endeavoured to exercise something like despotic authority over her partners.

Sweden's Deliverer. Christian II., sovereign of the three kingdoms, was a tyrant who would not endure opposition to his will; when he found much resistance in Sweden he ordered a massacre of some of the leading men in Stockholm, and thus roused the country against him. Gustavus Vasa, who belonged to the high nobility of Sweden, was one of those who led the movement against Denmark some time before. He was then treacherously seized and carried off to Denmark as a hostage. He escaped in disguise after a year, and returned to his country, where he tried, but without much success, to arouse the Swedes into an organised rising against the Danish power. He had to retire to Dalcaria, and led for some time a life of romantic wandering, working unrecognised, sometimes as a farm labourer and sometimes as a miner, with a great price on his head. At last, in 1520, the " Blood Bath " of Stockholm aroused the Swedes to passionate resistance, and then Gustavus Vasa came to the front, was welcomed by the people, and soon created and commanded an army large enough to make an effectual fight. It ended three years later in the capture of Stockholm, and the expulsion of the Danes from Sweden. Gustavus was raised to the throne as Gustavus I. in 1524, and in the following year the Union of Calmar was torn to pieces.

Development of the Country. Gustavus reigned for forty years, and his rule made Sweden once again a free and prosperous country, with a large army, a prosperous exchequer, and a thriving population. He established schools and colleges, and promoted education; opened up roads, bridges and canals throughout the country; made commercial treaties with other countries and did much to promote trade. He was devoted to the Lutheran faith, and did his best, like many other European princes, to suppress the Catholics. He died on September 29th, 1560, and was succeeded by his eldest son Eric XIV., whose rule was in every sense unfortunate, for he was practically a madman, and involved his country in costly and useless wars. After eight years he was deposed by his brother, John III., who was inclined to favour the Jesuits, like his son, Sigismund, who succeeded him in 1592. The Protestant party therefore deposed Sigismund in 1600, and made his uncle, Charles IX., king. Gustavus Adolphus, grandson of Gustavus Vasa, succeeded in 1611, as Gustavus II., who brought Sweden back to strength and prosperity such as she had not enjoyed since the days of his grandfather.

He came to the throne when he was seventeen owing to the disputed succession of his father. He secured the support of the nobles by confirming their privileges, reorganised the government, and created a large army; made war with Denmark and recovered the Baltic Provinces. He also made war on Russia, and this war was ended by the Treaty of Stolbova in 1617. By this treaty Sweden obtained Ingermanland, Karalia and part of Lavonia, while Russia recovered Novgorod. In 1618, Gustavus visited Germany, and two years later married the daughter of the Elector of Brandenburg. His dispute with Poland was ended in 1629 by a six years' truce.

Gustavus and Wallenstein. Gustavus was, like his grandfather, a Lutheran, and he raised an army to support the Protestants of Germany. These struggles brought into great prominence the celebrated Wallenstein, a great soldier of indomitable ambition. He made himself an object of dread to the Princes of the German Empire, who prevailed on the Emperor to dismiss him from the command of the army. The successes of Gustavus Adolphus, however, compelled the Emperor to restore Wallenstein on his own terms. Wallenstein raised a large army and obtained a success over Gustavus at the battle of Lutzen, in 1632; the result was for a long time uncertain, but in the end the army of Wallenstein was completely defeated by the Swedes. The battle was fatal to Gustavus. During the battle he received three wounds and fell from his horse to the ground. A soldier of the enemy asked " Who is there ? " " I was the King of Sweden," replied Adolphus, and the man shot him through the head.

His daughter, Christina, succeeded him, but in 1645 she resigned the crown to her cousin, Charles X. This King defeated Sigismund of Poland in a terrible battle at Warsaw in 1656, which lasted for three days, and he also succeeded in expelling the Danes from the continent of Sweden. He died in 1660, and his son, Charles XI.—then only a child—came to the throne.

Charles XI. was followed by the greatest King of Sweden since Gustavus Adolphus, Charles XII., often called " The Madman of the North," whose strange career has given a subject to many poets.

A Romantic Career. Charles XII. was born on June 27th, 1682. His succession was regarded by Russia, Poland, and Denmark as a favourable opportunity for an attack upon Sweden, but the young king, having some help from England, promptly compelled the Danes to make terms of peace, and afterwards defeated the Russian army at the famous battle of Nava, on November 30th, 1700. He dethroned King Augustus II. of Poland and compelled him to sign humiliating terms of peace in 1706. In the following year he led an army into Russia, and for a time drove the Russians before him; but he suddenly changed his plans, relying too much on the promises and counsels of the Cossack leader, Mazeppa, who has been made famous in poetry

of terrible privations for his troops, he laid siege to Pultowa, in Russia, he was completely defeated. He afterwards engaged in many other wars, won victories, suffered defeats, had thrilling escapes from capture and other dangers, and finally came to terms with the Tsar by ceding to him Sweden's Baltic Provinces. With the aid of the Tsar he proposed to conquer Norway, and then to make an expedition into Scotland and, with the help of the Jacobite party there, and of Cardinal Alberoni on the Continent, to replace the Stuart family on the throne. But all these venturesome plans were brought to an end, for Charles was killed while laying siege to Fredrikshall on December 11th, 1718.

SPAIN

From the time of the defeat of the Spanish Armada in 1588 the greatness of Spain gradually declined. Philip II. had been an absolute ruler, and had introduced the custom of raising money without the consent of the Cortes, which, indeed, was seldom summoned. The power of Spain by land and sea, her wealth, her industries, and even her population, decreased, and after the death of Philip II., in 1598, the history of Spain is chiefly told in the history of other countries. His son, Philip III., was much under the influence of favourites: he was succeeded in 1621 by Philip IV., who, though a man of some talents, had no capacity as a ruler. The story of the Thirty Years War and of the War of the Spanish Succession has already been told. Portugal and her colonies, which had become part of the Spanish dominions in 1580, were lost to Spain in 1640, after a brief struggle. Charles II. (1665—1700) had no children; with his death ended the Austrian dynasty, and Spain was now regarded by the great Powers of Europe as their prey.

Charles II. nominated as his successor the grandson of Louis XIV., and then came the War of the Spanish Succession. Philip V., who was proclaimed King at Madrid in 1700, was the first of the Bourbon Sovereigns. He introduced the Salic Law, which was the cause of much trouble later on. In 1724 he resigned his crown to his son, but on his death a few months later Philip again ruled—at least nominally, the country being really governed by his second wife, Queen Isabel, and Alberoni, her Minister. After Philip V. came Ferdinand VI., and then Charles III., the best of all the Bourbon Kings. He made many reforms in the government of the country, and under his rule Spain was more prosperous than she had been for many years. In 1788, Charles III. died, and was succeeded by his son, Charles IV., during whose reign occurred the French Revolution, which for a time changed the face of European politics.

PORTUGAL

We have already traced the history of Portugal from its earliest days to the discovery of the Brazils by Cabral in 1500. Cabral was born about 1460, and on March 9th, 1500, he was in command of a fleet bound for the East Indies.

a course too much to the west for the purposes of his voyage, came in for the full influence of the Atlantic's South American current, and was carried, whether he would or not, to the then unknown coast of Brazil. Thus, like Columbus, he discovered an entirely new region by accident. He was equal to the occasion, however, and, landing on the shore of Brazil, claimed the whole country as part of the dominions of the King of Portugal, and effected an easy conquest. He established the first commercial treaty between Portugal and India.

In 1524 was born Portugal's greatest poet, Camoens, author of "The Lusiads." Camoens had been intended for the Church, but he declined to take Orders, and occupied himself with the composition of poems. He got into trouble with the authorities at Lisbon, and was banished from the city for a year. After an absence of sixteen years, he returned to Portugal, and in 1572 published "The Lusiads," which won a brilliant success.

In 1580, Portugal was seized by Philip II. of Spain, while the Dutch shortly after captured the Portuguese settlements in India. The Portuguese were, however, well capable of resisting invasion, and in 1640 put an end to the Spanish occupation, and made John, Duke of Braganza, the Sovereign of the kingdom. The war lasted for a considerable time, and was brought to an end by the Treaty of Lisbon in 1668.

The Methuen Treaty. An important event in the history of Portugal was the concluding of the Methuen Treaty between Great Britain and Portugal, on December 27th, 1703, by Paul Methuen, the British Ambassador at Lisbon. It favoured the importation of port wine into the British territories by lowering the duty, thus discouraging the importation of French wines. The Treaty was abolished in 1834.

The more recent history of Portugal is brought into close association with that of England and of France, because of the struggles between France and Portugal in which England frequently gave her armed assistance to the Portuguese. Portugal has ever since remained an independent kingdom, and has been, in spite of troublous questions of succession, a prosperous country.

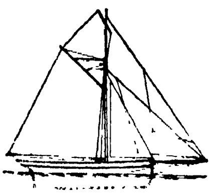
SHIPBUILDING
continued from
page 5262

TYPES OF MODERN SHIPS

Varieties of Sailing Ships and the Methods of Rigging them. Construction of Hulls. Steamers and Steamer Construction

By Dr. J. BRUHN

THE ships of to-day are classified into steam and sailing vessels according to their method of propulsion. There is a third type called the *auxiliary* ship, which is really a sailing vessel with a small steam-engine that can be used in case of calm. It is, however, very rarely met with now, it having been found that the purely steam or purely sail-propelled ship was in most circumstances the one that answered best. It was seen in the preceding article that the steamers now predominate to such an extent that it is only a question of a few years before sailing vessels will have practically ceased to exist. Even now the value of the world's sailing tonnage is only about one-tenth that of the steam tonnage. The steamers are further divided into single-screw, twin-screw, and paddle vessels, according to their method of propulsion. The turbine steamer is the latest addition to this category, but this description indicates only the type of the engines adopted. All these classes are again divided into three, according to the building material being wood, iron, or steel. There is also a mixed construction called *composite* where the framing is of steel or iron with wood planking, but it is very rarely adopted except in the case of yachts. The practical disappearance of wood and iron as shipbuilding material was also described in the preceding article. For practical purposes only steel ships are now built.

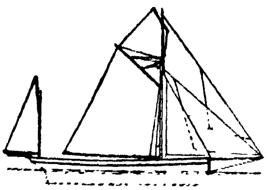


11. CUTTER

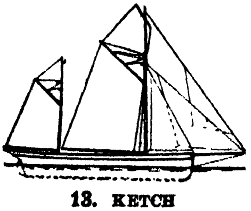
Steamers are further described according to their purpose as cargo, passenger, mail, coal-carrying, ore-carrying, oil-in-bulk steamers,. etc., but these categories are more or less vague, and usually merge into one another, so that it may not be possible to apply any one description alone to any individual vessel. In the general outward appearance the masts and funnels of a steamer form most prominent objects. They do not, however, convey much more information about the character of the vessel than the flagpoles and chimneys do with regard to a house. The very largest and most important steamer may have only one or two pole masts for signalling purposes, and a comparatively small cargo vessel may have half a dozen masts to suit the arrangement for loading and discharging cargo. On the other hand, the number of funnels is merely an indication of certain arrangements of boilers, and is no definite criterion to the power developed by the engines.

Sailing Ships. In the case of sailing ships the outward prominently apparent features—namely, their rig or general arrangement of masts and sails—afford practically the only means of classification. In other respects all sailing vessels are alike, being constructed merely to carry a load of any kind of cargo from one port to another.

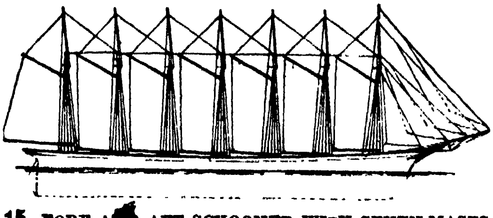
A knowledge of the various types of sailing ships is still essential to a naval architect, and a short description of them is therefore given here. To appreciate the differences between the various rigs it is necessary to know the broad principles of the disposition of sails. The masts of a ship are the nearly vertical spars that carry the sails. They are extended down through the decks to a firm foundation at the bottom of the vessel, and they are supported by strong wire ropes from their top to the sides of the deck or to the adjoining masts. At the fore end of all sailing ships a nearly horizontal spar is fitted, called the *bowsprit.* It serves the purpose of giving greater spread to the sails, which could otherwise be extended only over the length of the ship proper. Like the masts, it is supported by stays of wire rope, in this case to the stem of the ship and to the foremast. On the masts are hung spars to which the sails are made fast directly. There are three kinds of such spars—namely, yards, booms, and gaffs. The yard is, in its normal position, horizontal across the mast, and its sail hangs straight down in a plane at right angles to a fore-and-aft wind. It is, however, movable, so that the sail can be adjusted to suit the direction of the wind. The boom is, in its normal position, horizontal, and in a fore and-aft direction with regard to the ship. It is always on the after side of a mast and at the bottom of a sail which is, in its middle position, at right angles to a beam or side wind. The gaff is very similar to a boom, but is at the upper edge of a sail having a boom at the bottom one, and it is usually raised from the horizontal to an extent of 45 deg. or more. Both booms



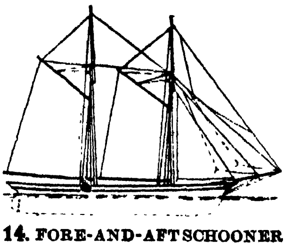
12. YAWL



13. KETCH

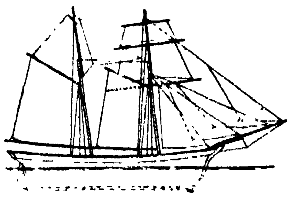


15. FORE-AND-AFT SCHOONER WITH SEVEN MASTS

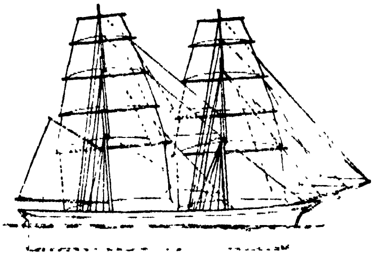


14. FORE-AND-AFT SCHOONER WITH TWO MASTS

and gaffs are movable, so that the sail they expand can be adjusted to the direction of the wind. Such sails are called *trysails*, to distinguish them from the square sails or yard sails. In addition to these classes of sails there is a third kind—namely, *staysails*, which are not extended directly by means of spars, but are fastened to the steel fore-and-aft stays supporting the masts and the bowsprit. They are always triangular in shape, and have their normal position in a fore-and-aft direction, like the trysails.

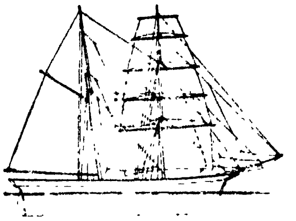


16. ORDINARY SCHOONER

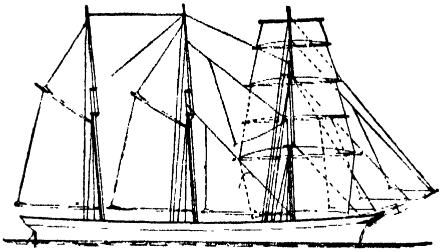


18. BRIG

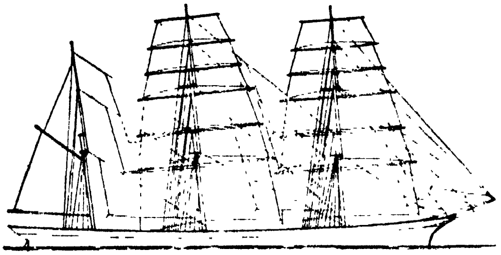
Name of Masts. Where two masts are fitted, the first one from the fore end is called the *foremast* (except where the second one is a subordinate one, in which case the first one is called the *mainmast*); the second full size mast is the main mast. Where there is a third mast it is called the *mizzen-mast*, and if there is a fourth one it is designated the *jigger-mast*, if without yards, or *after-mizzen-mast* if with yards. The spars on the individual masts are called by the name of the mast. Thus, there is the fore yard, the main gaff, and the mizzen boom. There are only one boom and one gaff on a mast, but there may be several yards. The bottom one is always the lower yard. The next one is the topsail yard, or if this sail is fitted in two parts, the lower-topsail yard. Above the topsail yard comes the topgallant yard, or if the topgallant sail is in two parts, the lower topgallant yard. Above the topgallant yard is the royal yard, and if there is a yard above the royal one it is called the skyscraper yard. The arrangement of the sails depends to a certain extent on the size of the ship. From the point of view of simplicity it would be desirable to have as few masts as possible; but for the larger ships this would involve the use of individually unhandy sails, hence the introduction of one or more additional masts.



17. BRIGANTINE

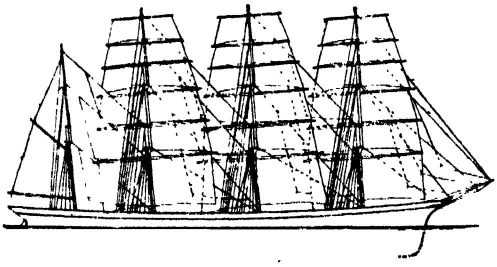


19. BARQUENTINE

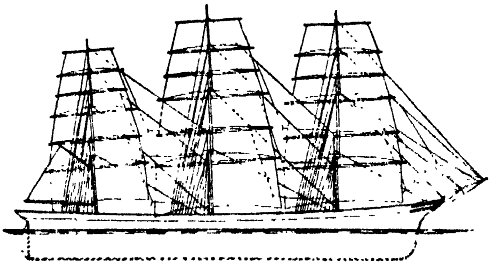


20. THREE-MASTED BARQUE

Types of Rigs. The *cutter rig* [11] is the one adopted in the smallest trading vessels, say from 50 to 80 ft. in length, and in yachts of moderate size. It has only one mast, the mainsail being extended by means of a gaff and a boom. The *yawl rig* is similar to that of a cutter with a very small mast fitted abaft the mainmast as shown by **12**. It is applied to vessels about 60 to 90 ft. in length. The *ketch rig* [**13**] is practically a yawl with the after mast of slightly larger dimensions. It is adapted for vessels ranging from 70 to 100 ft. in length. The *schooner rig* is the one found in the greatest number of varieties. It is the rig adopted for the smallest seagoing sailing merchant vessels, and it is the rig used for practically all steamers whatever their size, if they do carry sails at all. This type of rig is divided into fore-and-aft schooners and ordinary schooners. The former variety has no yard sails, whereas the latter has. In the fore-and-aft rig

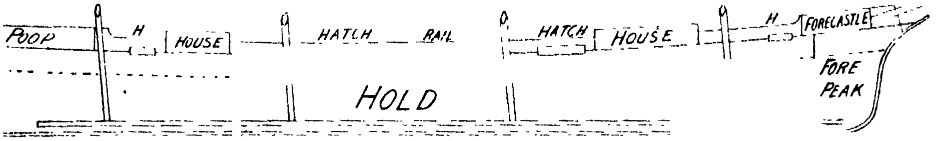


21. FOUR-MASTED BARQUE



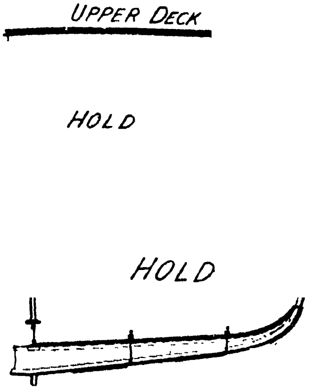
22. FULL-RIGGED SHIP

the sails are of the trysail type, and are usually identical in arrangement on all the masts. It is adopted for all sizes of ships from 80 ft. in length to 380 ft. In the smaller vessels two masts are fitted as shown by **14**, and in the larger ones as many as seven [**15**]. This rig is particularly favoured in America. The ordinary schooner rig is shown by **16**, and will be seen to consist of a foremast with yard topsail and topgallant sail, but a trysail instead of the lower yard sail, and a mainmast with trysail and topsail only. This is the usual arrangement, but sometimes there are yard top and topgallant sails on the mainmast also. As in the case of fore-and-aft rigged schooners, more than two masts may be fitted when the foremast only is usually fitted with yards. The lengths of ships with this type of rig may be said to range from 90 ft. upwards. The *brigantine rig* [**17**] is practically the ordinary schooner rig, except that a lower yard sail is fitted to the foremast instead of a trysail. On the sketch are also shown double yard topsails and a topgallant and royal sail, but this is not characteristic of this type and could also have been adopted in the schooner rig. The brigantine rig is used in vessels of 100 to 130 ft. in length. It is applicable only to ships with two masts, and is very rarely adopted now. The *brig* is another rare type of sailing ship. This rig is also applicable only to vessels with two masts, and 110 to 140 ft. in length. Fig. **18** shows that it is practically the brigantine rig with yards fitted on the mainmast, so that its sail arrangement becomes similar to that of the foremast. The *barquentine rig* is sometimes adopted for three-masted vessels of about 130 to 170 ft. in length. Figure **19** shows that it is similar to that of the brigantine with a mizzen-mast added. The *barque* is by far the most popular rig for modern sailing vessels, and is applied to ships from 150 ft. in length and upwards. This type of rig requires at least three masts, and is similar to the barquentine, except that yard sails are fitted on the mainmast as well as on the foremast. Figure **20** shows the three-masted type of this rig as it is applied to the great majority of steel ships of moderate size, say from 230 to 270 ft. in length. Figure **21** represents the four-masted barque rig, which is used for nearly all larger sailing vessels, say from 260 to 310 ft. in length. There have been a few five-masted barques in cases of vessels of upwards of 300 ft. in length. A *full-rigged ship* is shown in **22**. This form of rig has been more adopted as a standard than as the actual rig of ships. It must have at least three masts, and it will be seen that it is similar to the barque rig with yards fitted to the mizzen-mast, so that all the masts carry this form of spar. The yards shown in the illustration are, from below—the lower yard, the lower topsail yard, the upper topsail yard, the lower topgallant yard, the upper topgallant yard, and the royal yard. There have been a few four-masted full-rigged ships; and there is one five-masted, 400 ft. in length.



23. PROFILE OF FOUR-MASTED BARQUE

General Arrangement of Ships. Although the sailing vessel is now rarely built, it may conveniently be dealt with first on account of its greater simplicity in general arrangement. Figures **23** and **24** show the outline profile and the midship section respectively of an ordinary large modern four-masted barque, which may be taken as typical in general arrangement for all sailing ships, except in regard to the number of masts. The length of such vessels is from ten to twelve times their depth, and the breadth is from 1·6 to 1·8 times the depth. They consist practically of one huge receptacle for cargo. A few feet from the fore end a watertight bulkhead is fitted for safety in case of collision. But from this point to the after end, or stern, there is but one large hold, as shown by the elevation section or profile [**23**]. In the vertical direction the hold is sometimes divided by a lower deck 7 to 8 ft. below the upper deck, though more often only a tier of beams is fitted at this place. The construction of steel sailing ships is as simple in principle as their general arrangement. These vessels consist of a steel shell ranging from 5/16 in. in thickness in the smallest sizes to ⅝ in. in the largest ones. This comparatively thin plating is stiffened in the bottom by deep ribs called *floors*, as shown by **24**. They consist of plates ¼ to ½ in. in thickness and from 6 to 30 in. in depth in the smallest and largest vessels respectively. The side plating is stiffened by frame girders [**24**], which form the continuation of the floors. They range in depth from 3 to 6 in., and may be formed of various rolled steel sections.

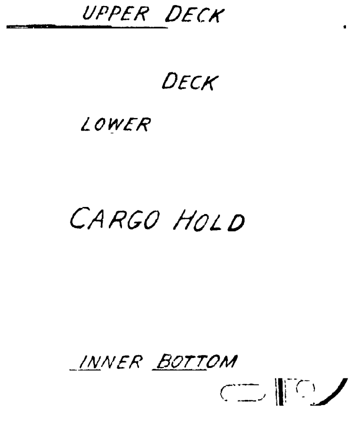


24. MIDSHIP SECTION OF FOUR-MASTED BARQUE

Details of Construction. At the top of the vessel the frames on the two sides are joined by the beams of the upper deck, which may or may not be fitted with steel plating, but are nearly always covered with wood planking from 3 to 4 in. in thickness. The beams themselves may be of various sections of rolled steel girders. If a lower deck is fitted, as is the case in all large sailing ships, it is similar to the upper deck. Both tiers of beams are supported at the middle of the ship by solid round iron pillars stepping on the centre keelson, which is a large girder formed of plates and angles on the top of the floor plates, as shown by **24**. If the vessel is very broad, there may be additional rows of deck supports called *quarter pillars* fitted between the middle and the side of the ship. The bottom of the vessel is usually fitted with a bar keel, ranging in size from 5 by 1½ in. to 12 by 3½ in., and terminating aft in the stern-post and forward in the stem, both of which are of about the same size as the keel. To distribute the effect of concentrated loads, girders are fitted on the top of the floors, where they are called *side* and *bilge keelsons*, and on the inside of the frames, where they are called *hold* or *side* stringers. On the top of the upper decks of sailing ships a forecastle is usually fitted. It is an erection at the fore end of the ship about 7 ft. in height. A poop, which is a similar erection at the after end, is also usual. In addition, there may be deck houses for the accommodation of the crew near the midships part of the vessel. In a few instances a bridge has been fitted, which is a midship structure similar to those formed at the ends by the poop and forecastle. Poops, bridges, and forecastles extend always to the side of the ships, so that their side plating is the continuation of the outside plating proper. They are sometimes used for cargo, but more often for living accommodation.

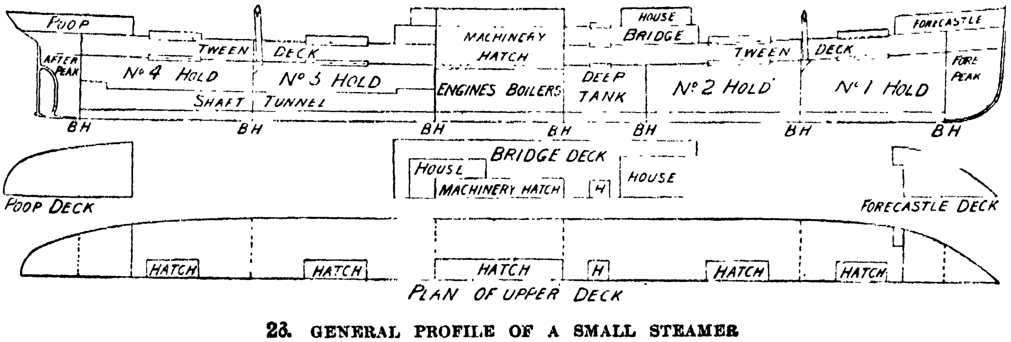
Arrangement of Steamers. The general arrangement of steamers is somewhat more complicated and more variable than that of sailing vessels. Steamships are, as a rule, relatively longer than those propelled by sail, the length being usually equal to eleven to thirteen times the depth. The breadth is from 1·4 to 2·0 times the depth. A bulkhead is always fitted near the fore end as in the case of sailing ships. The remainder of the ship is not, however, available entirely for cargo, but must also provide space for the propelling machinery and for the coal. It is usual to place the engines and boilers near the midship part of the vessel, as shown by **26**, but sometimes they are placed at the after end, particularly in small steamers, which may thereby obtain one large hold for the reception of cargo. Wherever the machinery space is, it is separated by means of steel water-tight bulkheads from the remainder of the vessel. If the machinery is amidships it is necessary in screw steamers to provide a tunnel through which the propeller shaft passes to the after end of the vessel, where the screw is fitted immediately forward of the rudder. Watertight bulkheads are a source of safety to any ship, as they tend to minimise the effect of a leak by confining the space to which the water gets access.

A steamer would be as safe as a sailing ship with the same number of bulkheads, but as the former is the more valuable, she is always subdivided to a greater extent than the latter. Figure **26** shows a steamer with seven watertight bulkheads, which is the usual for vessels over 350 ft. in length. Shorter steamers have fewer, and larger ones may have more watertight divisions than in this instance. The bottom of a steamer may be constructed, as in the case of the sailing ship shown in **24**, of a single thickness of plating. If the vessel is at all of a fair size, it is now almost invariably constructed with an inner bottom, as shown by **25**. This is another reason why a steamer is usually safer than a sailing vessel. The latter may, however, and sometimes does, possess this source of safety. From **26** it will be seen that the space provided in a steamer is divided up into several holds numbered from the fore end. These, again, may be divided by one or more decks. In **26**, only an upper and a lower deck are shown. As the engines and boilers do not occupy the entire space from side to side of the ship, it is usual to provide bunkers here for the coal to be used on the voyage. If enough space is not available here, the cargo hold immediately in front of the boilers is encroached on for this purpose.



25. SECTION AMIDSHIPS OF A CARGO STEAMER

Deck Erections. The character of the upper part of a steamer varies considerably. The top deck may be what is called *flush*—that is, without any erections except casings covering the engine and boiler room openings, and smaller deck houses, such as chart and steering houses. The uppermost deck may also have a poop and a forecastle above it, as in most sailing vessels, or one only of these erections may be fitted, but the most common arrangement is that a poop and a forecastle is fitted at the after and fore end of the vessel as shown by **26**, and a bridge over the midships portion. The bridge is not merely a convenient place for the necessary cabin accommodation in a steamer, but it adds to the safety of the vessel by protecting the large machinery openings from the sea. It is very common for poops, bridges and forecastles to be extended so that there is only a short space between them, which is then called a *well*. In some instances the erections join and form a complete upper structure. The vessel is then called an *awning* or *shelter-deck* steamer, the upper deck being the awning or shelter deck. Above this deck there may possibly be



26. GENERAL PROFILE OF A SMALL STEAMER

other erections. Most sailing ships, if they have to carry ballast, must use stone, sand or gravel. Steamers now always use water for this purpose, as, where the power is at hand it is much more easily let in and discharged by means of filling pipes and pumps. Where a double bottom is fitted, it can be used for the purpose of carrying water ballast. Where the amount thus provided for is insufficient, and where there is no double bottom, the necessary space is provided by a so-called *deep tank*, which is simply a small hold set apart for this purpose, but which may be used for cargo or coal when required. Figure **26** shows one such deep tank immediately in front of the boiler hold. Large steamers may have two deep tanks.

Construction of Steamers. In construction, as in general arrangement, steamers differ more than sailing ships. The outside shell plating is similar in both types. On the whole there is no variation at all in the arrangement of this part of a ship's structure. It consists of individual plates of smaller or larger sizes fitted in a fore-and-aft direction, and as steamers are built of very much larger dimensions than sailing vessels, its thickness ranges from $\frac{5}{16}$ in. in the smallest to 1 in. in the largest ships. The single bottoms of steamers are constructed similarly to those of sailing ships shown by **24**. If an inner bottom is fitted, the floor plates are deeper and thinner, and are lightened by large holes being cut in them as indicated by **25**. The greater depth is required to allow of sufficient space between the two bottoms for every part of the structure to be accessible, and to produce sufficient capacity for water ballast. The inner bottom is fitted on the top of the floors, and consists of plating $\frac{1}{8}$ in. to $\frac{1}{4}$ in. thinner than the corresponding outside plating. At the side of the vessel where the inner bottom terminates, ordinary frame girders are fitted to stiffen the plating. At the top of the frames the beams of the upper deck tie the two sides of the vessel together, as in sailing ships, but in the arrangement of the structure below this deck there is again considerable variety in steamers. There may be only one huge hold below the upper deck with very strong frame girders at the side, or there may be a lower steel deck as shown in **25**, which supports the sides to such an extent that the frame girders may be of smaller size. There might have been a third and even a fourth tier of beams with decks laid on them. Generally speaking, the number of the decks increases with the size of the vessel, but this is to a large extent a question of convenience. In passenger steamers decks are necessary to provide for cabin accommodation, but in cargo vessels a capacious hold may be required.

Framing and Beams. Where the depth from the bottom to the lowest deck is large, and where, consequently, frame girders of considerable dimensions would be required to support the sides properly, a special arrangement of framing is sometimes adopted, consisting of a few very deep plate frames, called *web frames*, fitted at intervals. The ordinary frames can then be of much smaller dimensions, when they are supported by fore-and-aft girders or stringers from web frame to web frame. The beams or decks are supported by means of pillars from the bottom of the vessel. There is at least one row of these supports, but there may be two or three. In cargo holds it is usually desirable to do with as few of these obstructions as is possible, and they are consequently often fitted at a considerable distance apart in the fore-and-aft direction, and have a girder fitted at their heads for the support of the intermediate beams.

Machinery. The engines and boilers used on board ship differ but little in general principle from those on land. But even in a moderately large steamer the power required to drive her through the water at a reasonable speed is in excess of what is sufficient for land purposes except in very special instances. In the smallest of steamers the indicated horse-power amounts to some hundreds, in a moderately large one it may be some thousands, and in a very large one it may be tens of thousands. As the weight of the engines, boilers and coal has to be carried by the ship at the expense of a similar amount of cargo, it follows that it is doubly desirable that marine engines and boilers should be of the lightest construction consistent with absolute safety, and should be of the most economical design as regards coal consumption. A ship engine must also be able to be governed more completely and quickly than a land engine, owing to the continual changes it may often be necessary to make in the speed of a ship. The type of boiler now almost universally adopted in steamers is that known as the Scotch tubular marine boiler, where the flames from the fire are carried through tubes surrounded by water. In a few instances the so-called water-tube boilers have been adopted in merchant ships. In these the water is in the tubes with the flames playing round them. This type of boiler is much lighter than the ordinary one, but it has not been found so reliable all round.

The engines used in a steamer are almost invariably of the inverted direct-acting surface-condensing description. They may be compound, triple or quadruple expansion in their action. Those belonging to the last category are the most economical as regards coal consumption, the steam being used four times before it is condensed. As the power required becomes larger, the number of boilers is increased in preference to increasing their size. Two is the ordinary number, but in large and fast steamers there may be more than a dozen double-ended boilers. When the engines would be inconveniently large, two propellers are adopted. This may also be done where the size of a single propeller would be too large for the draft of the vessel.

Practical Training. In this and the previous article a rough outline has been given of what a modern ship is like, and of the way in which it arrived at its present state of evolution. Such imparted information must, however, always be a poor substitute for that which is gained by the intending shipbuilder during a practical apprenticeship, when he can become thoroughly familiar with all the details of ships as they are. In the following articles the actual building of ships will be dealt with. In the first instance it will be assumed that it has been mutually agreed between the shipowner and the shipbuilder what the prospective vessel is to be like. In other words, the ship has been designed. Drawings showing the general arrangement, a model showing the form, and a specification setting forth the other details having been decided upon, it remains for the shipbuilder only to produce the desired structure.

HOW TO PRESERVE FOOD

Cold Storage. Refrigerating Machines. Milk Pasteurisation and Refrigeration. Tinned Foods. Chemical Preservatives

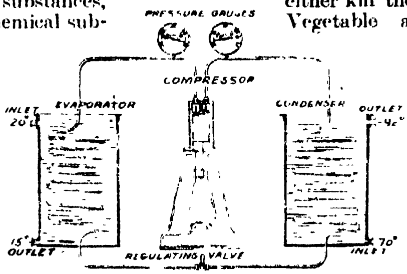
Group 16
FOOD SUPPLY
17

Continued from page 5318

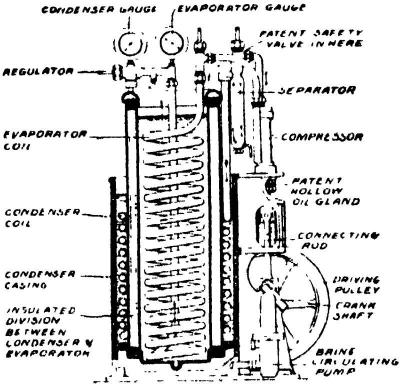
By CLAYTON BEADLE and HENRY P. STEVENS

It is a common matter of everyday experience that most foods, especially those of animal origin, are subject to decomposition if kept beyond a certain period. Before we can properly appreciate the value of the different methods of preserving foods it is absolutely necessary for us to form a clear conception of the causes which bring about decomposition and putrefaction.

Why Food will not Keep. Foods are mixtures of complex organic substances, and when they go bad these chemical substances undergo chemical changes with the formation of other substances characterised by their unpleasant taste and smell, or by poisonous properties. These chemical changes are brought about by minute organisms (micro-organisms), which are invisible to the naked eye. [See Bacteriology]. All decomposing substances, when examined under the microscope, are seen to be swarming with innumerable organisms of varying shape and form. They are so universal that it is no easy matter to prepare liquids free from them and keep them in this state. Water taken from any pond, well or stream, even fresh rain water, teems with life when examined in this way. Like all living things, these micro-organisms bring about the chemical transformation of matter by "feeding on," or absorbing, substances in one form and excreting them in another, or else producing ferments which bring about these changes. It often happens that substances produced by one organism become the food of another, so that a whole series of chemical changes are brought about. This happens when any animal foodstuff undergoes putrefaction. The danger of consuming such food lies in the small quantities of poisonous products (ptomaines) they may contain. In the early stages of decomposition food is often covered with furry growths, commonly known as moulds. These are well characterised forms of plant life. They are of considerable importance as they prepare the way for the development of other more minute organisms and bacteria. If only we could exclude these organisms, it might be possible to preserve even the most perishable of foods indefinitely.



1. REFRIGERATING MACHINE
[Diagrammatic view]

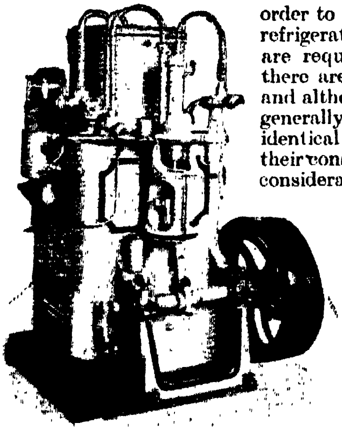


2. SECTION OF A LAND TYPE OF REFRIGERATING MACHINE

How Bacteria are Kept in Check. Having shown that food will not keep because of the action of micro-organisms, it will now be our business to inquire into the conditions under which they live, in order that we may learn how to control them. The spores, or seeds, are extremely minute, are always found floating in the air, and are continually settling like dust on every object. Wherever they find favourable conditions and suitable surroundings they quickly obtain a foothold, and breed and multiply. These conditions may be classed under four heads: (1) Supply of suitable food; (2) presence of moisture; (3) suitable conditions of temperature; (4) absence of substances which either kill them or prevent them developing. Vegetable and animal matter, including foods for human consumption, all provide suitable food for micro-organisms, but it is essential for their development that moisture should be present, hence the primitive method of preserving food by drying, and therefore excluding moisture. Thoroughly dried foodstuffs will keep an immense time. The organisms may be there, but have not a chance of developing.

Cold Storage. Food may be preserved by taking advantage of the fact that bacteria will only develop within a certain range of temperature. Thus below about 50° F. their activity is almost entirely arrested; above 170° F. bacteria are destroyed. We shall confine our attention, to start with, to those methods of preservation dependent upon low temperatures, and generally known as refrigeration, or cold storage. The food, whether meat, fish, vegetables, or fruit, is kept at a low temperature until required for consumption. This is perhaps the best method of preserving food as it adds nothing to and takes nothing from the article, so that no change is brought about, and the food remains as nutritious and digestible as before treatment. The advantages of cold storage will become apparent when we see some of the disadvantages attached to the other methods of preserving food. By the aid of cold storage hundreds of thousands of tons of different foodstuffs are imported annually into this country without the use of any chemical preservative. When the ship arrives here the foodstuffs are taken out of the refrigerating chambers, and placed in cold stores until required. We shall now describe the machinery and plant used in this connection.

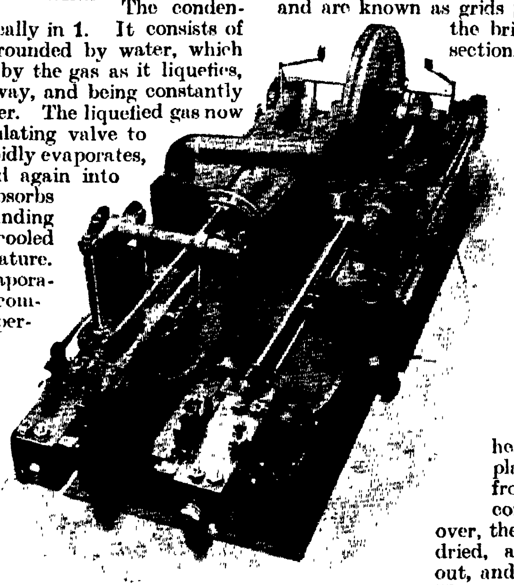
Refrigerating Machines. The rooms in which foodstuffs are stored are generally kept cool by a system of overhead pipes through which cooled brine circulates. Brine is chosen, as it can be reduced to a low temperature without freezing. In



3. LAND TYPE OF CARBONIC ANHYDRIDE REFRIGERATING MACHINE

order to cool this brine refrigerating machines are required, of which there are several types, and although those now generally employed are identical in principle, their construction varies considerably. The principle involved is as follows:

By means of a compressor, certain easily liquefied gases, such as carbon dioxide, ammonia, or sulphur dioxide, are condensed to a liquid in a condenser. The condenser is shown diagrammatically in **1**. It consists of a long coil of tubing surrounded by water, which absorbs the heat given out by the gas as it liquefies, the warm water passing away, and being constantly replaced by fresh, cold water. The liquefied gas now passes on through a regulating valve to the evaporator, where it rapidly evaporates, the liquid being converted again into vapour; in doing this it absorbs heat from the brine surrounding it, so that the latter is cooled down to a low temperature. The gas, as it leaves the evaporator, passes again to the compressor, and the cycle of operations is repeated. Provided there are no leaks, no fresh gas is required, since it is used over and over again.

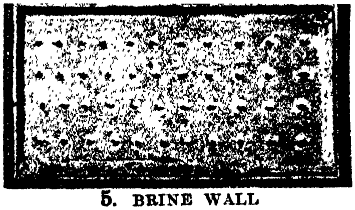


4. MARINE TYPE OF CARBONIC ANHYDRIDE REFRIGERATING MACHINE

The Chief Gases Employed. Opinions differ as to the most suitable gas, but we may mention three which can be used—namely, carbon dioxide (carbonic anhydride), ammonia, and sulphur dioxide gases. Carbon dioxide gas is cheap, costing only a few pence per pound. On the other hand, ammonia has the advantage that it is liquefied at a lower pressure. While carbon dioxide requires, in temperate climates, a pressure of 850 lb. per square inch for liquefaction, ammonia may be worked at a moderate pressure of about 120 lb. to the square inch. On the other hand, all compressor parts of the carbonic acid plant are much smaller. Ammonia is an alkaline gas, and in the presence of air will dissolve copper and other metals, so that in ammonia machines all copper, or copper alloy, must be avoided in any parts which come in contact with the ammonia. This is a great drawback to the use of ammonia machines where only sea-water is available for cooling, as the iron pipes, which alone can be used, are quickly corroded by sea-water. If it should escape, the smell is objectionable, though scarcely unpleasant, and in case of a serious escape it would prove dangerous. Sulphur dioxide is, perhaps, the least suitable of all three. It is not difficult to liquefy, but is more corrosive, especially as it is liable to be converted, by oxidation, to sulphuric acid in the presence of air and moisture.

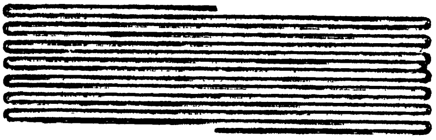
In connection with cold storage we shall describe machines worked with carbon dioxide gas, but will treat of a machine using ammonia gas when dealing with the cooling of pasteurised milk.

Cold Storage Chambers. Figure **2** shows, in section, the construction of a carbonic anhydride refrigerating machine. Fig. **3** is an illustration of this machine, which, of course, can be used not only for cooling brine for cold storage chambers, but also for making ice, cooling water, or all purposes combined. It will be seen, as illustrated in **1**, that the compressor forces the gas into the coils of the condenser, which are contained in an annular vessel surrounding the evaporator, a space fitted with an insulating material being left between the two. The crank shaft not only works the compressor, but also a small pump, which drives the cooled brine from the inner vessel, and causes it to circulate through the pipes in the cold storage rooms. These brine tubes are made in long lengths, sometimes 200 ft., electrically welded, and are known as grids [**6**]. In large installations, the brine grids are divided into sections, each section having a separate return pipe back to the machine, where valves are placed for regulating the quantity of cold brine circulating in each section as required by the temperature in the room; a system of this kind is necessary in order to obtain a regular temperature in the cold stores. The grids are generally fixed at the top of each room under the ceiling, and, the air in contact with the pipes becoming colder, and consequently heavier, descends, and is replaced by "less cold" air from beneath, producing a constant circulation. Moreover, the air is not only cooled but dried, as the moisture separates out, and condenses on the grids. The quantity of cooled brine contained in the system of grids is very considerable, and this acts as a reservoir of "cold," so that in many cases it is unnecessary to run the refrigerating machine continually, but only for a few hours daily.



5. BRINE WALL

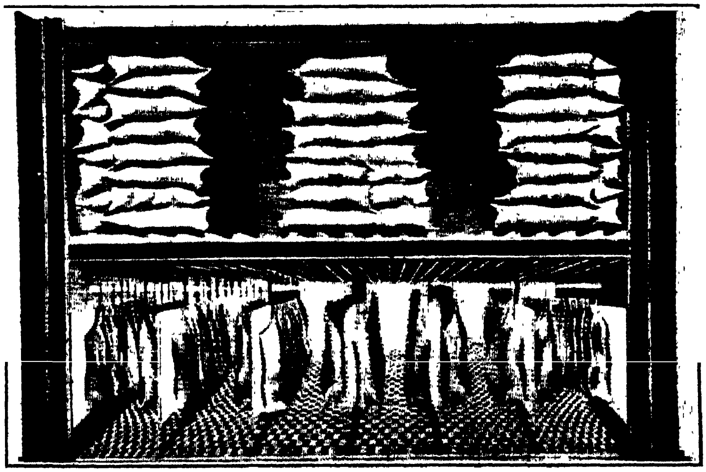
In some cases, especially when storing butter above 32° F, and all kinds of fruit, a circulation of cold air is preferable for cooling the chambers, in which case a number of grids are placed together in convenient proximity to the refrigerating machine, and air is drawn through them by means of a powerful fan, and conducted by means of air ducts to the cold rooms. In some meat-freezing works it is the practice to install brine walls, which consist of large, flat, very shallow boxes [5] made of steel plates placed parallel to each other at convenient distances, through which the cool brine is circulated. In the passages between these walls the meat to be frozen or chilled is hung, as illustrated in **7**. The brine grids are seen beneath the ceiling, and the brine walls between the rows of carcases. In the rooms overhead, fitted with brine grids, the frozen meat is stored. The brine system is also largely used for bacon curing. The sides of bacon are hung up in rooms chilled by brine pipes, and generally with cold air circulation to 40°F., which temperature minimises the tendency to putrefaction, while, on the other hand, it is the lowest temperature at which the meat will "take" the salt perfectly. Fruit can also be very advantageously stored in cool chambers, either for carriage over long distances, or to keep back a glut until a time at which it will fetch a considerably enhanced price.



6. BRINE GRID

Refrigeration in Factories. Another instance in which refrigeration may usefully be applied is in cooling chocolate, in order to hasten and facilitate the removal of the tablets from the moulds. This is a very difficult operation in summer under ordinary conditions, when the chocolate tends to adhere to the moulds, making it necessary sometimes to remelt and cast again.

Brewing is a delicate operation depending on the growth of yeast, which is much influenced by temperature. A refrigerating machine is therefore of great importance in a brewery, where it is used to cool a large quantity of water for refrigerating the "wort" and maintaining the correct temperature in the "tuns." Moreover, the finished beer should be bottled at a low temperature.



7. BRINE WALL SYSTEM OF FREEZING AND CHILLING MEAT

Multifarious as are the uses of cold storage on land, it is, if possible, of greater importance in the shipping of frozen meat from our Colonies. For such purposes large marine-type machines are employed, as shown in **4**. while for preserving passengers' provisions the machines illustrated in **8** are used. The principle in all these machines is similar to that already described. Figure **9** shows a typical installation for the carriage of frozen meat on board a White Star vessel, on the system of Messrs. J. & E. Hall, Ltd., to whom we are indebted for illustrations **1-9**.

Preservation of Milk. We now come to another important application of the principle of refrigeration—the treatment of milk. There are very few substances which are commonly used for human consumption so susceptible to the action of bacteria as milk and cream. The rapid decay of these substances, which is commonly and popularly called "souring," is caused by the presence of micro-organisms. It is well known that "souring" goes on much more quickly in warm weather than in cooler weather, and it is likewise known that milk can be kept from turning for certain periods by being put "on ice," or in an ice safe. It is, of course, simply a case of arrested growth of bacteria; the organisms themselves are not destroyed by this action.

Pasteurisation. The process of pasteurisation, which may appear to be rather mysterious to persons not familiar with it, is a comparatively simple operation. In reality, it is a process of heating the milk or cream to a temperature that will destroy the disease germs and chilling it at once in order to prevent the spores from germinating and setting up another generation of micro-organisms. The rapidity with which these spores develop is astonishing, and the practical way of dealing with milk is to deal with it as quickly as possible after being taken from the cow, chill it down at once, and keep it at a low temperature. [See AGRICULTURE, pages 4036-7 and 4209.]

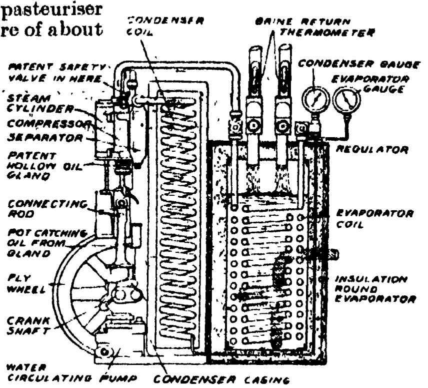
Public opinion, combined with legal necessity, fixes the standard which the practical dairyman must attain, and the demands upon the dairyman are constantly becoming more and more severe.

There are, of course, difficulties connected with the process of pasteurisation, and they lie in the accomplishment of the desired result without injuring the milk or changing its consistency, for which machinery properly adapted to the purpose is essential. Properly pasteurised milk has been recommended by the best physicians.

The ordinary pasteuriser which has hitherto been used is shown in **10**, and consists more or less broadly of a vertical cylindrical vessel surrounded by a steam jacket. Within the vessel is placed a vertical spindle having a paddle or stirrer fixed to it, driven by suitable gearing from any source of power. The steam is turned on to the jacket, the milk allowed to flow into the machine, and the paddle set in motion. It is assumed that the whole of the milk becomes pasteurised in being rapidly stirred round and thrown against the steam-jacketed sides of the cylinder. Unfortunately, this assumption is not quite correct, as a portion of the milk does not come into contact with the heated sides of the cylinder, and passes away through the outlet without having been raised to the requisite temperature to destroy the micro-organisms.

On the other hand, much of the milk is heated to too high a point, and coagulation of the albumen results, impairing the digestibility of the milk. Although the outflow from the pasteuriser may give the correct temperature of about 165°, it will be evident that some of the milk has been heated too much, and some insufficiently heated.

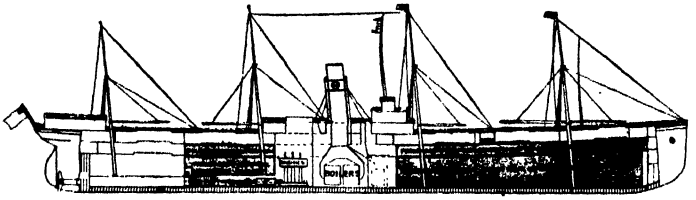
It should be mentioned that another drawback connected with the vertical pasteuriser with revolving spindle is that the step or joint upon or through which the spindle is situated forms a pocket where a little liquid is likely to remain, providing an ideal habitat for bacteria.



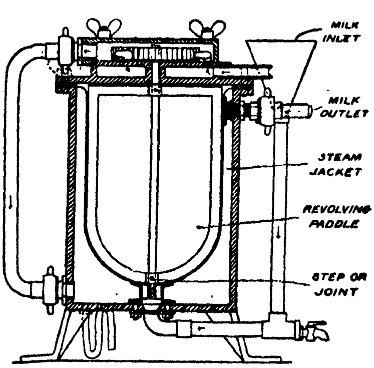
8. SECTION OF MARINE TYPE OF REFRIGERATING MACHINE

New form of Pasteuriser. In the newer type of machine the milk does not pass through a cylinder, and is not knocked about by a revolving paddle, but flows over a series of revolving drums which are semi-submerged in milk troughs.

In the case of the machine illustrated [11] the milk is allowed to flow slowly into the top trough, in which revolves a tinned copper corrugated drum, through which hot water passes at the requisite temperature. As the drum revolves, a film of milk adheres to it, and is carried over with it and heated to the right point. The outflow from the top trough is taken to a point where the heated milk naturally flows off, and none can go over excepting that which has been brought over by the revolving drum and properly heated. No milk can be overheated, and every particle of milk comes into contact with the drum without being churned or otherwise knocked about. In the second trough is a second revolving drum, through which ordinary water is constantly flowing. This water reduces the temperature of the milk to about 60°, and the milk then flows out into the third trough. A circulation of cold brine at about 35° passes through the third revolving drum, and reduces the milk to about 40°, at which point the milk flows out into a suitable receptacle.



9. SECTION OF A SHIP, SHOWING REFRIGERATING CHAMBERS



10. MILK PASTEURISER

In many modern dairies a cold-storage room at 38° to 40° is provided, and milk placed in it when it does not go out immediately for consumption.

The revolving drums are made of hard rolled copper, tinned all over, and the milk troughs, which are round at the bottom, are made of the same material. There is, therefore, nothing that can contaminate the milk, and the revolving drums are thoroughly cleaned after use by being revolved while a brush is held against them, warm water being placed in each trough during the operation. This machine constitutes a pasteurising and chilling apparatus in one frame, but where the older types of pasteurisers are used the milk flows out from them over a flat cooler. These coolers reduce the milk to about 40° as it runs off into the large cans in which it is sent by rail.

The Milk Refrigerating Machine. The next important item to consider in connection with milk pasteurisation and chilling plant is the refrigerating machine, which is necessary to produce brine at a low enough temperature to chill the milk to the requisite point.

We have already described machines worked with carbon dioxide gas. The one we shall now describe uses ammonia gas [12]. Any escape of gas is prevented by doing away with the reciprocating and compressor rod and stuffing-box, and by carrying the crank shaft horizontally through a self-sealing gland. The principle of refrigerating machines has already been explained. The gas enters at A through the pipe B, and thence into the piston C. D is the suction valve through which the gas passes as the piston descends; then, as it ascends again, the gas is compressed and driven through the passages F and up the discharge pipe F, into the condenser coils, HH, where it is cooled by the surrounding water and liquefied, collecting in a receiver. The liquid then flows to the expansion coils in the cooling apparatus, where it produces the desired refrigerating effect in the action of boiling off to gas again. The ammonia gas thus obtained is returned to the machine to be again liquefied, and the cycle is repeated.

The machine is actuated by the pulley P, attached to the crank shaft L, which revolves in an oil bath and also seals the packing joint M.

In larger machines the condenser is placed apart from the compressor, as plant would otherwise be too bulky and cumbersome. It is built of two tubes, one placed inside the other; through the inner one runs the water which cools the ammonia compressed into the space between it and the outer tube. The construction of the coils is shown in 14, and 13 is a view of the coil. This form of construction is far superior to the old type, where the ammonia gas was condensed in a flat coil of pipes, the gas flowing downwards inside the pipe and the water trickling downwards over the outside. The water in this case, being free to evaporate, brought about a certain lowering of temperature; on the other hand, the water getting warm in its descent ran over the bottom pipes when hottest, while the ammonia was endeavouring to liquefy inside these same pipes, with consequent re-evaporation of some of the liquefied ammonia and loss of efficiency.

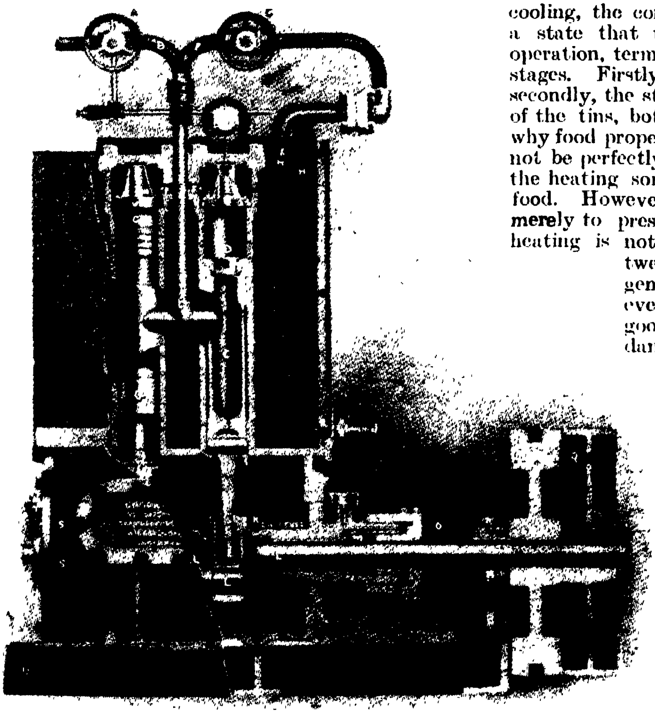
The modern plant for dealing with milk mainly consists, therefore, of an efficient pasteurising machine and a simple and efficient refrigerating machine, with the necessary steam for the heating drum and the power to drive the pulleys on the pasteurising and refrigerating machines.

11. MILK PASTEURISING AND CHILLING APPARATUS
(The covers have been removed)

Removal of Dirt. Owing to the manner in which milk is produced, and at present handled at the farms, it seems almost impossible to exclude dust and dirt. An apparatus which has been lately introduced is a strainer of exceedingly fine mesh having about 1,440 holes to the square inch. Such a fine gauze would be immediately stopped up if it were stationary and the milk simply poured through it. The strainer surface is therefore made in the form of a hoop, and is rotated as the milk flows through it. The rotating gauze hoop is constantly cleaned by a revolving brush, and passes under the milk in an open and clean condition. It is an established proof and fact that milk treated in the above-mentioned manner, properly cleaned, pasteurised and cooled, will keep about 18 hours longer under ordinary conditions than milk which has not been so treated, and it will keep in good condition for from seven to 10 days if placed in a cold room at 30°-40° F. The illustrations **10-14** have been supplied by Messrs. A. G. Enock & Co., Ltd.

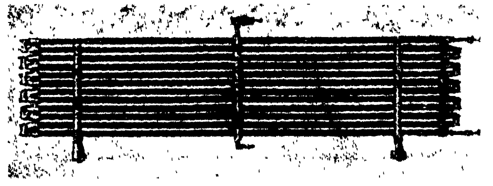
Tinned, Potted, and Bottled Goods. The method adopted in sterilising milk may be applied to numerous other foodstuffs. The principle of the canning process is simply this: The food is heated to about 170° F., in order to destroy bacteria, and the vessel sealed while hot. On cooling, the contents remain sterilised and in such a state that they will keep indefinitely. This operation, termed *processing*, is carried out in three stages. Firstly, the preparation of the foodstuff; secondly, the sterilisation; and, thirdly, the sealing of the tins, bottles, or jars. We know no reason why food properly prepared in this manner should not be perfectly harmless and nutritious, although the heating somewhat alters the character of the food. However, as it is the object of the packer merely to preserve and not to cook the food, the heating is not prolonged more than necessary, twenty minutes to half an hour being generally sufficient. There are, however, certain dangers common to canned goods. In the first place, there is the danger of the acid juices, especially in the case of fruits, having some action on the tin or solder, but cases of poisoning from this cause are very rare, and most of those recorded were probably due to quite another cause—namely, formation of ptomaines. At any rate, the danger can be easily avoided, if there be any, by using earthenware or glass vessels instead of metal ones.

Ptomaine Poisoning. The chief danger, however, arises from unsound tins, such as "pricked" tins—that is to say, tins inefficiently closed down, or which have been damaged so that the air has gained access to the contents. Tins are sometimes found "blown." This is owing



12. AMMONIA REFRIGERATING MACHINE

to incomplete sterilisation, bacterial action setting in after sealing, with the production of gaseous substances, causing a pressure inside the tin. There is always a partial vacuum in sound tins, so that when opened the air rushes in to them with a peculiar sound. If the tin has been imperfectly sealed, or if the sterilisation has not been complete, bacterial action is sure to set in, with the result that the extremely poisonous bodies, ptomaines, are produced. These are the causes of most cases of poisoning from eating tinned goods, especially tinned meat and fish, which are particularly liable to undergo such putrefactive changes. Sometimes, in the preliminary treatment, the foodstuff is treated with chemical preservatives in order to cover defective canning. This practice is to be condemned unhesitatingly, for if the canning be efficiently carried out there is no need for such preservatives. Chemical preservatives are, however, used very largely in food not destined to be canned, especially such as easily undergoes decomposition and putrefaction. We shall have to consider these chemical preservatives somewhat in detail.



13. COIL OF DOUBLE-TUBE AMMONIA CONDENSER

Preservatives in Common Use. Common salt is about the oldest preservative we know of, but at the same time it is very ineffectual. In most cases large quantities are required. Where used it is often supplemented by the addition of some powerful preservative. Of chemical preservatives, borax and boracic acid are perhaps more commonly employed than any others. They are, however, very mild in their action, and the quantity used must not be too small. Numerous experiments have shown that less than 4 gr. to the pint is practically useless in preserving milk, and the quantity often recommended to be added is quite double this. Borax and boracic acid are also used largely for butter, cream, potted meat, and many other foods, and the question naturally arises whether they are harmful, and whether restrictions should be put upon their use. Boracic acid is frequently administered medicinally, the maximum dose being 15 gr.; that of borax is 20 gr. It is evident, therefore, that in the case of young children and invalids, who practically live on milk, the quantity taken daily, even putting it so low as 4 gr. to the pint, would exceed the maximum pharmaceutical dose. Such cases illustrate the danger which may attend its use. On the other hand, it is difficult to say how far it would affect a healthy adult, although the recent elaborate experiments of Dr. Wiley seemed to show that even in that case it is likely to prove harmful. Nor can it be claimed that its use is necessary, as some of the largest wholesale dairymen bring their milk to London and other large towns from great distances, and manage to dispose of it without the use of any preservative whatever. Much the same considerations apply to butter, but we must bear in mind that it is not consumed to the same extent as milk by infants and invalids; and as to cream, the great difficulties in the way of preserving cream, even for a short while in the hot weather, makes the use of a preservative pardonable. There is, however, no need for the use of any preservative in the case of meat or fish, which should be kept fresh by cold storage or other means.

Preservatives to be Avoided. Passing now to *formaline*, another preservative, we are on somewhat different ground. No one can assert that formaline is harmless, and its use as a preservative should be prohibited. Nevertheless, it is occasionally found in milk, and is sometimes sprayed over meat, fish, and fruit to preserve them. It has a peculiar action on the gelatinous constituents of foods, hardening them and rendering them insoluble, and thus very difficult to digest. *Salicylic acid* is another preservative, found especially in preserved fruits, temperance beverages, sacramental wines, lager beer, etc. It is probably more dangerous than borax, and its use is seldom, if ever, justified. People differ very much in their susceptibility to salicylic acid. Many people—according to some authorities, 60 per cent.—are easily affected by small doses of the drug, causing symptoms known as salicylism, including deafness, headache, delirium, etc. The use of salicylic acid in food should, therefore, be regarded with great suspicion. *Sodium sulphite* is another chemical preservative which is occasionally found, especially in stale meat, as it has the peculiar property of imparting the bright red colour of fresh meat. It also acts as a deodorant, and masks the offensive odours which are produced in the first stages of putrefaction. *Fluorides*, usually sodium or potassium fluoride, have been found in butter, and their use should be prohibited.

Frauds on the Public. With regard to all these chemical preservatives, the weaker ones, in small quantities, are not of very great value, and the stronger ones are dangerous. Moreover, their use must be regarded as a fraud upon the public, as they impart to the foodstuffs a deceptive appearance of freshness. Thus borax or boracic acid, although they have a certain inhibitory power on the micro-organisms, which bring about the souring of milk, probably have little or no effect on the more dangerous pathogenic bacteria, so that milk preserved with borax, although it may appear still fresh and palatable, is, nevertheless, as stale as if it had gone sour.

Unfortunately, legislation, as it affects preservatives, is extremely unsatisfactory in this country. Although the report of the Departmental Commission appointed to deal with this subject made certain recommendations as to what preservatives should be permissible, and in what proportions these recommendations have not been adopted by the Board of Agriculture, and have consequently remained a dead letter, with the result that conflicting decisions in the courts are the general rule.

THE CAUSES OF DISEASE

The Cause and Prevention of the Most Common Forms of Disease. How Disease is Spread. Statistics

By Dr. A. T. SCHOFIELD

We have to speak first of the prevention of endemic disease, or diseases that attach themselves to and recur in a place rather than those which spread from person to person by infection, which are called epidemics.

Phthisis. Consumption depends on three things—the soil, the sower, and the seed; and without these three things the disease does not occur. The soil is the weakened lung tissue, prepared, first, by hereditary tendencies or, secondly, by repeated bronchitis or other lung diseases. The seed is the bacillus of tubercle, the tiny germ to whose ravages the disease is due. The sower is the fatal opportunity when the seed gets so firmly implanted in the lung that it can multiply. All of us are breathing the germs daily without injury. It is only the combination of all these things that produces the disease.

Phthisis does not depend on temperature; it is common in Greenland, in English cities, and in the West Indies. It does not depend on latitude; in Norway, Holland, and Italy the death-rate from it is the same—2·5 per 1,000. It destroys native races (Maories and Sandwich Islanders) because they are not accustomed to it, and have developed no resisting power.

Towns such as Rome, Naples, London, Edinburgh, have the same death-rate from it. It is not dependent on humidity; the Hebrides and Shetlands are very free from it. It is less common in the Navy than in the Army.

It is not prevented by even temperature alone. A combination of variation and dampness favour its spread, as at Alexandria and Port Said. Even and dry climates hinder it, as on the Nile and in Lower Egypt. A damp soil strongly favours the disease, which, however, is at bottom an infectious one, the germs being principally conveyed by the dust of dried sputum of consumptive people.

Where Consumption is Rare. Consumption is rare at high altitudes, and in people who live in the open air. Switzerland has the lowest death-rate from it. It is mostly found in Europe at elevations below 1,500 ft., where its death-rate is 2·15 per 1,000. From 3 ft. to 4,000 ft. it is 1·9. At 5,000 ft. it is only 1·0.

A great predisposing cause is over-crowding and indoor life, with its associations of foul air; though Mexican and Andean cities, at 7,000 ft. to 13,000 ft. high, although overcrowded, have but little phthisis, and it is rare in the crowded tents of the Bedouin Arabs.

Phthisis is largely influenced by the mode of living, and according to whether one is brought into contact with dusts and foul air.

Of 1,000 deaths among fishermen, 108 are from phthisis; among grocers, 167; among drapers, 301; among poulterers, 461; among farmers, 103; among cutlers, 371; among earthenware makers, 473; among operatives, 220; among woolsorters, 265; among coal-miners, 126—coal dust is not so injurious as other dusts.

Consumption undoubtedly increases with bad air: 70 per cent. of the patients at Brompton Hospital have led indoor lives. The increase of consumption is directly in proportion to the density of the population. It is also due to heredity, for from one-third to two-thirds of the children of consumptive parents develop consumption. The breath itself of consumptive people is not probably the source of infection, but the sputa. The disease clings to sick-rooms and confined dwellings. There is a record of nine successive cases in one travelling van.

Is Consumption Preventable? Phthisis is theoretically preventable, but practically its prevention is attended with many difficulties. Since 1861 the death-rate from this disease every five years has decreased as follows: 2·5, 2·4, 2·2, 2·0, 1·8 per 1,000. In 1851-60 it was $\frac{1}{8}$ per 1,000 of all deaths. In 1880-90 it was only $\frac{1}{11}$.

The chief predisposing cause of phthisis is bad, close air. The mortality in huts is two-fifths of that in barracks. Improved ventilation has recently lowered the death-rate.

Cattle suffer from tuberculosis. Infection may be caused by diseased meat or milk, though this has been disputed by Professor Koch. Bacilli are found in the milk of tuberculous cows.

Sanitation alone does not lessen consumption unless it drains and dries the soil. At Stafford it has made no change. Phthisis and damp soils go together. Where the soil has been dried, the mortality from phthisis has lessened to this extent: at Salisbury, 50 per cent.; at Rugby, 45 per cent.; Leicester, 30 per cent.; Bristol, 22 per cent.

In damp soils consumption, bronchitis, rheumatic fever, measles, whooping-cough, and pneumonia flourish.

Scrofula. One variety of this disease is tuberculous. It is common in close, confined, damp, dark rooms.

Rickets. The predisposing causes of rickets are too rapid child-bearing, weak parents, poverty, bad air, bad food, vegetable diet taken too early in life, and an absence of lime salts from the food. It was found in the Zoo that all the young lions developed rickets when they were fed on horseflesh, because the bones were too hard to crunch. When fed on goat's meat, where the bones are softer, the rickets disappeared, because the animals got the lime salts. Other cases are due to foul air, damp, cold cellars and want of sunlight.

Rheumatic Fever. Of cases of rheumatic fever, 27 per cent. are from inherited tendency. It arises from occupation, outdoor work, chills, poverty, and certain cold, damp soils. Damp houses and damp linen are very likely to bring it on. Close air is also bad.

Malaria. An "unhealthy" climate means almost invariably a "malarial" one. It is due to the bite of a mosquito, a species of *anopheles*, found in warm climates, drying marshes, stagnant pools and fen countries. Malaria is thus common when there is much moisture and decomposing vegetation—in old estuaries, alluvial soil, deltas and damp bases of mountain ranges, and freshly-cleared forest lands. It is least common in winter. The mosquitos are carried by winds across plains. A forest is a great protection, so is a large sheet of clear water, and a dry subsoil and good drainage.

We now turn to the consideration of the prevention of epidemics. With regard to these, the old terms "miasma," "contagion," "infection," have either disappeared or have been modified in their meaning since the discovery of the micro-organisms, which are the invariable cause.

The means of infection are practically by air, water, food, and clothing. In this case again, as in consumption, we require the soil, the sower, and the seed. Epidemics are most common in spring and autumn. They may be divided into *pandemics*, or those which seem to spread everywhere at once, such as influenza (at certain times), and *epidemics proper*, or those which ravage districts.

Those borne by water are typhoid, cholera, dysentery, diarrhœa, and sometimes scarlet fever. All the rest are carried by air, especially smallpox, chicken-pox, scarlet fever, typhus fever, measles, German measles, whooping-cough, mumps, diphtheria, and tuberculosis. Ague, leprosy, plague, typhus fever, are more or less extinct in England.

Cholera. Cholera is believed to be due to the "comma" bacillus, or perhaps to two varieties. The incubation is from one to fifteen days, generally two to five. It is a specific, zymotic, epidemic disease—a filth disease, carried by filthy people to filthy places; but filth alone cannot produce it. It is endemic in Lower Bengal and Central Asia. It is most fatal among negroes. It is commonest in autumn, and reappears in spring. Winter stops it. Infants are exempt from it. It is most common between the ages of 20 and 30. Poverty tends to increase it. It infects by the evacuations, which increase in virulence for three days. There are four stages: (1) *Invasion* and diarrhœa; (2) *exacerbation*, and subnormal temperature starts; (3) *collapse*, and the body drained of fluid; (4) *reaction*, and rise of temperature and recovery. Fifty per cent. of those attacked die in about 30 hours. All stools should be *buried*. Bacilli remain active in the body eleven days after death. All bodies, therefore, should be soaked in carbolic.

Cholera cannot be stopped by quarantine, and is not due to air waves. We eat it and drink it; we cannot "catch" it—that is, through the air. Epidemics occurred in this country in 1831, 1848, 1854, 1866, 1892. It is brought from the Ganges by pilgrims and caravans, and used to take three years to come. Now, by trains and steamers, it can arrive in three months.

The Holy Well at Mecca is a great centre, where pilgrims suffering from it wash and then drink the water. Some 38,000 die each year. At Hamburg, the Elbe has been found swarming with it; in the River Durance, 300 germs per cubic centimetre were found before the river entered the town, and 4,000 after; for on its banks were 20 corn mills using grain from Russia and India, where it had been trodden out by cholera-stricken natives. In 1866, a man landed at Southampton; he came to London, his evacuations passed into the River Lea, which is used as drinking water, and caused 16,000 deaths.

There are three lines of defence against this disease: Isolation at ports of all infected people and articles, the Metropolitan Asylum Board Hospitals, and the action of the Town and District Councils and Medical Officers of Health. The chief object in a cholera epidemic is prevention rather than cure. The sick should have beds of straw, which should be burned. All diarrhœa should be checked, and little fruit eaten, and only fresh-boiled fluids drunk.

Smallpox. The smallpox rash appears on the third day; there are 14 days previously of incubation. The rash begins with red pimples, which then fill with water (vesicles), and then with matter (pustules). There is a pain in the back, and the infection lasts four weeks. Smallpox hospitals tend to infect houses round them. The smallpox infection is doubled in houses a quarter of a mile off compared with those half a mile away. The germs are diffused in fine dust, and have great resisting power to heat and cold, and are spread by clothes more readily than scarlet fever.

MEAN ANNUAL DEATHS FROM SMALLPOX

	At all	0–5	5–10	15–25	25–45
Vaccination optional .	305	1,617	337	109	
Vaccination compulsory	114	242		122	

Before inoculation was practised there was an epidemic in this country every three years, afterwards every ten. The maximum mortality was at the end of May. When inoculation began, only one-tenth of all attacked died, but the disease spread everywhere, because there was no proper vaccination, but only *inoculation* with the disease itself. In 1838, free vaccination was established, and in 1853 it was made compulsory.

People are thus protected (1) by having had smallpox; (2) by inoculation with smallpox; and (3) by vaccination with cowpox.

Cowpox may be described as a sort of smallpox in the cow. The table given above is of interest.

Vaccination in infancy loses half its protective power at twenty years of age. Isolation is no substitute for vaccination.

Before 1853, the deaths from smallpox were ·4 per 1,000; since 1853 ·2; now, only ·001 of all deaths are due to this disease. This great decrease is in children under ten years of age. At fifteen years of age the death rate increases, because none have now had it in youth, for the vaccination protects them. Revaccination at 15 is not compulsory, but gives immunity for the rest of life.

The following table gives the figures of hospital mortality in 5,000 cases of smallpox among patients of all ages:

	Under 15 yrs. of age	Over 15 yrs. of age
	per cent.	per cent.
Vaccinated with bad marks ..	4	10
,, one good mark	0	
,, two good marks	0	4·6
,, three good marks	0	2·0

Thirty-eight per cent. of the patients who died were unvaccinated.

If unvaccinated, generally 35 per cent. of those attacked die.

If previously vaccinated, 19 per cent. die.
If vaccinated with no mark, 23 ,, ,, ,,
If vaccinated with 1 mark, 7 ,,
If vaccinated with 2 marks, 4 ,,
If vaccinated with 3 marks, 1·5 ,,
If vaccinated with 4 marks, ·5 ,

If vaccination were now stopped, smallpox would at once become a very fatal disease, being new. At Sheffield, four out of five had it, and two out of five died when there was no vaccination. Smallpox cost the rates from £7 to £11 a case; 5,000 cases cost £43,300 in three months. In 1,572 cases, 30 per cent. of the unvaccinated died, and only 3·5 of those vaccinated.

Before vaccination, the deaths from smallpox were 3,000 per million, now they are 175. At Sheffield, the proportion of deaths among children under ten who were unvaccinated was 480 to 1.

Inoculation (now discontinued) consisted in injecting a diluted smallpox into the body, and with vaccination (cowpox) this is in time to take effect, even if smallpox is in the system, for hydrophobia and smallpox incubate twelve days, and cowpox only eight days; therefore, if smallpox be "caught" on Sunday, vaccination on Tuesday would be effectual. In mild outbreaks, the germ may have become weakened by passing through persons of slight susceptibility.

Typhoid. The mortality in cases of typhoid used to be 33 per cent.; now, about 17 per cent. die in the third week. Children suffer less than adults. There is first about 14 days of ordinary diarrhœa, and then the fever and disease set in. Patients die of perforation, exhaustion, and slow bronchitis. Forty thousand have died in this country in one year, and it is still one of the greatest scourges in the Army. Our precautions against it were very unsuccessful in the Boer War, and compare unfavourably in every way with those of the Japanese Army in the late war. Good nursing is of the utmost importance, but prevention is easier than cure. Typhoid is due to a special germ. There is a similar disease in cows, conveyed by milk.

An outbreak took place in Worthing through leakage from an infected sewer of subsoil water into a well through a fissure. Another outbreak arose from drinking herb beer made in a room where a patient had lain. The infection is from the excreta. The germ does not live long in sewage, nor in rain water; but if nitrites are formed by filtration through the soil, etc., it can live on these for a long time. It abounds in shallow wells.

The general health rate in towns is really determined by the death-rate from typhoid. Of 49 rats inoculated with typhoid, and breathing sewer gas, 37 died; of 49 rats inoculated, and breathing pure air, 3 died; of 72 guinea-pigs inoculated, and breathing sewer gas, 57 died; of 72 guinea-pigs inoculated, and breathing pure air, none died.

Diphtheria. Diphtheria is conveyed through the air at short distances, and is most fatal to patients of from one to ten years, and especially between the ages of three and six. The incubation is one week.

Infants are not exempt, and it attacks both sexes, rich and poor alike. It used to be most common in the country; it is now most common in the town. It began 60 years ago, and is most frequent in winter. It is endemic in Paris and Florence. Diphtheria is due to a specific germ. Darkness, dampness, dirt, ash-pits, appear to favour it, but it is doubtful if it comes from drains. It is caught often by kissing, and is common after scarlet fever; there is also an hereditary tendency.

Where membrane forms, one-third of those attacked used to die before the anti-toxin was used; but the mortality is now much reduced, for protection by anti-toxin is very great, and may reach immunity. In malignant cases patients may die in twenty-four hours. The poison lurks about for weeks afterwards, so that patients must be strictly isolated till all membrane is gone. Ten per cent. of those attacked have slight paralysis after. Cats can take diphtheria, and cows can transmit a similar disease by milk, not by water. Anti-toxin is got from horses kept near Harrow, which, by repeated injections of doses of diphtheritic poison of increasing strength, develop in the serum of their blood so much anti-toxin against diphtheria that they are used as storehouses for it. They are in perfect health and do nothing, but are occasionally blistered, when a small amount of the fluid is drawn off and used. The writer has seen a little girl with her throat and nose filled with thick, white membrane, and a short time after injecting the anti-toxin he has seen it melt away like snow before the sun, and the child, who would have died, recover.

Measles. In measles, the rash appears on the fourth day, and often attacks eyes and ears, and leaves deafness. In adult life it is a serious disease. "Black" measles are dangerous. In countries where it is rare, it is very fatal, but in England we are hardened against it. The infectious germ is largely carried in the air by sneezing and coughing, also by clothes; but not by water, milk, or animals.

Whooping-cough. Whooping-cough is the most fatal disease for children under five, and is infectious for six weeks.

Chicken-pox. Chicken-pox is usually mild. Fresh crops of spots continue to come out for six days. Incubation lasts fourteen days.

Scarlet Fever. Scarlet fever is most common in children under three. Infection is caught by the breath, or, in the later stages, by bits of infectious skin. The fever can be conveyed by milk from a similar disease in a cow, but is not conveyed by water, or carried far by air currents. Many escape altogether; it is therefore well to protect young children. Over three, they are less susceptible, and it is less dangerous. It is most prevalent in autumn. The incubation is under a week.

Typhus. Typhus is nearly extinct in England. It is carried by the air short distances, and about 18 per cent. of cases are fatal.

The present (lowest) mortality from these diseases per 1,000 per annum is as follows:

Diphtheria	·1	Whooping-cough	·6
Typhoid	·2	Diarrhœa	·6
Measles	·3	Measles	·6
Scarlet fever	·4	Phthisis	1·3

Any death-rate from these diseases which exceeds this should be inquired into at once.

Influenza. Influenza, or the "influence of the stars or weather," is due to a "dumb-bell" bacillus. It is an infectious, contagious disease in the air carried from person to person. The incubation is from two to seven days, and people remain infected one week after the symptoms go. The earliest recorded outbreak occurred as early as the year 887; more recent ones in 1803, 1833, 1837, 1847, 1889, 1891, and since. It occurs at all seasons, and attacks nearly all Europe at once (pandemic). It can travel in one night from Moscow to Vienna.

There are four varieties known—digestive, respiratory, locomotor, and nervous. In 1890, 28,000 died, which shows what an enormous number must have been sick, for the writer has seen hundreds affected, but not one who has died. It caused the death-rate to rise to 46 from 18. It has one-third of the incubation of small-pox; hence, while 10 people are getting small-pox, 1,000 may get influenza. There is no rash, and it is not easily recognised, and it attacks adults freely, because so few are protected. It is like a common cold, but much more severe, and therefore difficult to isolate. One attack, unfortunately, gives but little protection.

Isolation should be practised when old people are exposed to it, and when it is the first case in a new locality. Where it rages large gatherings should be forbidden. All prophylactics, such as camphor, oranges, or drugs, are useless. It is of the first importance to be in generally good health when attacked, and there should be no exposure to cold till recovery is complete. The nervous variety often leaves the mind disturbed, while the respiratory is often accompanied by severe, and sometimes fatal, pneumonia. The digestive and locomotor varieties are less dangerous.

Influenza is supposed to have originated in Eastern China.

Erysipelas. The mortality of this disease, like scarlet fever, is in inverse ratio to the rainfall, for damp checks perspiration, which is so conducive to recovery. It always enters through some wound; the germ cannot penetrate the healthy skin.

Epidemic Infantile Diarrhœa. This is endemic in Preston and Leicester. When the temperature 5 ft. below the surface is 56°, the germs rise, and infection begins. In the first quarter of a year in Leicester there were 27 deaths from it; in the second there were 29; in the third (during July, August, and September) there were 925; in the fourth, 44, showing that it is only in certain seasons that it rages. It abounds in loose, porous, foul, damp, and "made" soils.

The temperature at 4 ft. below the surface determines the activity of the germ, which is increased by stagnant air and bad food, and is most common in poverty, dirt, darkness, and crowded localities.

Less Common Diseases. Continued Fever is a name given to mild forms of some of the specific diseases. Yellow fever appears in the West Indies, Mexico, Brazil, West Africa. The incubation is from one to five days, and lasts from two to three weeks. Relapsing fever is due to a spiral bacteria. There is a sudden onset and sweating for seven days; then, after another seven days, this is repeated. It is common where there is overcrowding and want of food. Anthrax and Woolsorters' Disease and Splenic Fever are closely allied diseases taken from sheep and cattle. Glanders, or farcy, is a nasal discharge, with gland swellings, common in horses, but rare in man. Tetanus, or lockjaw, is a disease of garden soils, where the germ swarms. It is not infectious, and arises from fouling some wound (a cut finger, for instance) with the soil; hence it is commonly "taken" through the hands and feet.

Following POWER from page 5376

By JOSEPH G. HORNER

AFTER the invention of the printing press, that of the steam engine has contributed more than any other to develop the civilisation of the human race. Without it the great machines that relieve men of manual toil—the spinning and weaving machines, the lathes, and various metal-shaping machines—would have been undeveloped. The enormous postal service, the ocean steamers, the expresses, would have been unknown. Yet it, together with the vast industries which it has created, was struggling into birth so recently as the period when Dr. Johnson paced his beloved Fleet Street. The men who created the charming literature of the eighteenth century cared nothing for the new agent which was coming into being. Watt enjoyed, perhaps, as much notoriety as any engineer of the period. But Dr. Johnson, when visiting Birmingham, did not think it worth his while to accompany Boswell to see the famous works where about 700 "hands" were employed. The attitude of culture towards mechanical subjects was reflected in Johnson's remark to Boswell in reference to the people of Lichfield. "Sir, we are a city of philosophers; we work with our heads, and make the boobies of Birmingham work for us with their hands." Little notice, therefore, was taken of the work of the engineers. Even the great canals which Brindley had cut for the Duke of Bridgewater were apparently never alluded to by Dr. Johnson. Bramah, Maudslay, and their fellows found no place in contemporary literature. The literary class knew nothing of Cort and Onions—men whose inventions and discoveries profoundly influenced the metallurgy of iron, and through it the civilisation of the present period. Now there are many millions of horse-power of work done daily in the world by the steam engines.

The Power Behind the Engine. Many people are so accustomed to associate the action of steam as such with the power of the engine that they often overlook the essential agent. For steam is but one vehicle of power, one only of several that are possible. The real agent is *heat*, and heat is obtainable apart from steam. We may be pardoned for putting this essential fact in language taken from Herbert Spencer, who began life as an engineer, in which he must have achieved distinction had he not chosen to devote his immense talents to the pursuit of science and philosophy. "The late George Stephenson was one of the first to recognise the fact that the force impelling his locomotive originally emanated from the sun. Step by step we go back from the motion of the piston to the evaporation of the water, thence to the heat evolved during the oxidation of coal; thence to the assimilation of carbon by the plants, of whose imbedded remains coal consists; thence to the carbonic acid from which their carbon was obtained; and thence to the rays of light that deoxidised this carbonic acid. Solar forces, millions of years ago expended on the earth's vegetation, and since locked up beneath its surface, now smelt the metals required for our machines, turn the lathes by which the machines are shaped, work them when put together, and distribute the fabrics they produce."

The Nature of Heat. In the eighteenth century, steam engines were manufactured at a period when utterly false theories prevailed respecting the nature of heat. In the philosophical treatises of that time the term "caloric" occurs constantly, and both steam engines and hot-air engines were long termed *caloric engines.* It was then believed that heat was an imponderable but material and indestructible fluid, which insinuated itself between the pores of bodies, and which possessed gravity; and the term caloric has lingered on, even into the present period. Count Rumford disposed of the old theory by showing experimentally that heat and mechanical work were interchangeable, inasmuch as heat might be produced by work, and work could be done by the application of heat. Heat, therefore, as we all know now, is one of the many forms of energy in the universe, and as such it is measurable in thermal units, representing a definite number of pounds, 772 lifted a foot high, or as kilogrammes, 424 lifted a metre high. Hence the science of heat is termed *thermodynamics*, and the first law of thermodynamics is this—that when work is transformed into heat, or heat into work, the quantity of work is mechanically equivalent to the quantity of heat.

Heat is utilised in various ways—in the steam engine, in the form of aqueous vapour; in the gas and oil engines, in the gaseous products of combustion; in hot-air engines, in the form of atmospheric air subjected to rapid changes of temperature. But in any case mechanical work results only when there is a change from a *higher* to a *lower* temperature, which expresses the second law of thermodynamics. An obvious corollary is that the greater the range between the higher and lower temperatures the greater must be the efficiency of the heat engine. Incidentally, this explains why the pressure of steam and gas employed in engines (and consequently their temperatures) have always been increasing, and continue to do so still.

The Vehicle through which Heat Works. Every one knows that the moving agency in a steam engine is a piston, enclosed in a cylinder, and actuated by the pressure of steam on its opposite sides alternately. So far, so good. But why should steam possess sufficient force to press with a load of many tons at one instant on the piston of a large engine? Steam is a highly heated gaseous fluid, very much hotter than the water from which it is generated. Now, the hotter a gas is, the more active are its molecules. These are incessantly flying to and fro, hammering against one another, and against the sides of any vessel in which they may happen to be contained; and the result, in common language, is not molecular activity, but *pressure.* In actual fact then, since increased heat produces increased activity, driving the molecules farther asunder, the active motive power in the steam engine is heat, and the steam is simply a vehicle for the supply of the heat. One would, therefore, expect to find that heat other than that of steam would do similar work, and such, in fact, is the case. In fact, from the theoretical point of view, the vehicle utilised may be ignored entirely—*the heat is the essential thing*. For Carnot has shown that if any two temperatures are chosen, a higher and a lower, the efficiency of an engine working between those temperatures depends on the difference in temperatures, and not at all on the substance employed. All reversible engines, therefore, which fulfil this condition have theoretically the same efficiency, irrespective of the working substance which is the agent of temperature changes. Hot air, coal gas, blast furnace gas, producer gas, the vapour of petroleum, are all used to a very large extent, and their resulting action is the same as that of steam, though the method of their utilisation is not precisely the same. Into the relative economies of these we need not enter here. It is sufficient to have established the fact that the steam engine is simply a heat engine, for which steam is just a very convenient vehicle. Actually, there are excellent reasons why some agents are less suitable than others; why heated atmospheric air, for example, is vastly less useful under practical conditions than the vapour of water or the hydrocarbons produced by the combustion of coal or oils.

How to Utilise the Heat of Steam. The first practical point which arises relates to the nature of the vessel in which temperature reduction is to be accomplished with economy. It may consist of one or more vessels. The most familiar type is the cylinder of the steam engine. But a single cylinder is a crude form, because the range of temperature possible in one cylinder is not extensive enough to permit the highest range of expansion which is either desirable or possible when the range is divided between two cylinders (*compound*), three (*triple expansion*), or four cylinders (*quadruple expansion*). The point, therefore, is that the object sought, in order to ensure high efficiency, is to bring the steam (the heat carrier) into the first cylinder at as high a temperature as is practicable, and to cause it to escape (*exhaust*) finally at the lowest temperature that is practically possible. Stated in this way, the problem does not strike one as being very difficult, yet in the growing approximations thereto lies much of the history of the steam engine for the past 150 years.

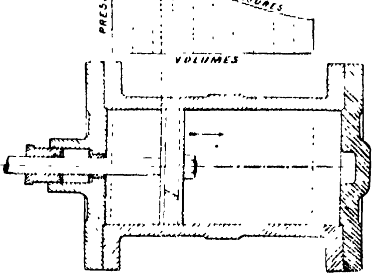
The Meaning of Expansion. The term *expansion* has been employed. The fact which it expresses is inseparably associated with pressure and temperature. From the present point of view it is a property possessed only by gaseous fluids. Solids and liquids expand slightly, but not in the same sense that gases do. Thus, a vessel may be half-filled with a liquid; this will not expand sufficiently to fill the vessel, but raise its temperature sufficiently to convert it into a gas, and the gas will expand and fill the vessel, or another many hundreds of times larger. In the transition from the liquid to the gaseous state, it has received *heat* and expanded; and if it is caused to resume the liquid state by condensation, it will in doing so yield up that heat and shrink back to its former dimensions. A gas cannot be retained and made to do useful work by its expansion in an open vessel, but only in one that is closed and rendered impervious to the passage of the gas. Without this capacity for expansion, the heat absorbed by a gas in passing into the gaseous state would be of no value in the engine. A red-hot mass of metal would be useless as a vehicle of heat energy, because it would be incapable of expansion, and without expansion pressure would not result.

The force exercised by an expanding gas is termed its *elastic force*, and this is the equivalent of *heat energy*. Hence we say that the elastic force of steam is an invariable quantity at a given pressure and temperature. With increase in these, elastic force increases, and consequently the power exerted. So, therefore, by increasing pressure and temperature of steam in a vessel (the *cylinder*) the power of the engine can be multiplied without increasing its dimensions, which fact explains why small engines now give out much more power than large ones formerly did.

We arrive, then, at the fact that in any heat engine the work done is proportional to pressure and temperature, and that the engine does work by reason of the energy manifested as heat, which produces expansion of the heated gas, its vehicle. Pursuing the subject into another stage, let us see what goes on in an engine cylinder to which steam has been admitted.

The Way in which Expansion Takes Place. The pressure of the expanding steam operates against the face of a piston which is free to move along the cylinder, and which is connected by its rod to the rotational mechanism of the engine. If now steam is admitted at one end of the cylinder, it pushes the piston to the other end. And in order to do so the steam may be admitted as long as the piston is moving—that is, throughout its entire stroke. This was the old way, which was extremely wasteful of steam, because its expansive force was not properly utilised. But the steam supply may alternatively be *cut off* at a definite stage, as at one-quarter, one-third, one-half, three-quarters, or seven-eighths of the stroke. This is the modern method, in which the steam is made to do work during the remainder of the stroke by virtue of its expansive energy [1]. Or, further, the steam, partly expanded in one cylinder, may be exhausted into a second cylinder to move a piston there by its expansive force, and thence into a third cylinder to move its piston similarly, as in the compound expansion engines.

The Curve of Expansion. But considering simply what goes on in a single cylinder, we know that, according to Boyle's law, the pressure of a gas in expanding (under a constant temperature) varies inversely as the space which it occupies. Though steam (unless superheated) is not a perfect gas, yet for the present purpose it may be regarded as such. If, therefore, steam is admitted into a cylinder during, say, a fourth of the stroke, and then cut off, the curve of pressures will be a falling one, as in 1. The average of all the ordinates measured in the diagram of work will be the average pressure exerted during the stroke. In other words, the area of the space enclosed by the straight and curved lines shows the amount of work done by the steam during each stroke of the piston.



1. CURVES OF STEAM PRESSURE

The curve of expansion in an engine cylinder does not fulfil Boyle's law, for then it would be an isothermal one, or one of equal temperature, which is impossible. Since a portion of the heat in the gas in expanding becomes converted into mechanical work, the temperature of the gas must fall, for that, as we have seen, is an essential condition of convertibility. But supposing that fresh heat were applied to the steam during its expansion, sufficient to compensate for the heat lost as work, then Boyle's law would hold good, and the curve of expansion would be an *isothermal* one. An approximation to this is secured by the *steam-jacket*—the casing of hot steam which surrounds most engine cylinders. This represents the best condition for general practice. Sufficient heat is imparted thus during expansion to prevent liquefaction of the steam that would otherwise result from the rapid yielding up of its heat. The question of very high pressures and superheating opens up other problems, which may be deferred to a later stage.

The Engine Compared with a Gun. Should there be an initial difficulty in realising the elastic force of steam that is bottled up in a cylinder behind a piston free to move, the subject may be apprehended better from another point of view. If for the cylinder a gun, a charge of gunpowder, and a projectile are substituted, we shall see analogies between the two. The ignition of the gunpowder generates an immense volume of hot gas, the expansion of which, accompanied by pressure, drives out the projectile with much initial energy. The parallel between the gun and the engine cylinder is absolutely complete in its essentials, notwithstanding that the action of the gunpowder is more energetic and rapid than that of the steam. The fact that the steam is produced in a separate generator (the boiler) and the gas is generated within the gun is a matter of detail only. Actually, in the gas engines and petrol engines the explosive gas is generated within the cylinder, hence the term *internal combustion* engines applied to those great groups. But the gun is as truly an internal combustion engine as the gas and petrol motors are.

Early Engines. Having briefly explained the nature of the power behind the engine, the remainder of this article may be occupied with a rapid survey of the epoch-making developments in the history of this group of prime movers.

It is a curious fact that the first engines were not steam engines. To us it seems now so very natural to utilise steam in certain fashions in the engine that these methods seem almost self-evident. But the accomplishment of this is the outcome of as remarkable a story in the history of invention as any in the annals of engineering.

Atmospheric Engines. The first engines, then called *fire engines*, were not driven by steam at all, but by the weight of the atmosphere. The steam was used only because it could be condensed from atmospheric pressure, leaving a moderate vacuum. Papin's engine consisted essentially of a cylinder of metal with an air-tight piston fitting easily therein. The power given out by the engine was developed by the descent of the piston. The piston descended by gravity, and the conditions necessary for descent were fulfilled by the production of a vacuum underneath the piston. But herein lay the impracticable element in Papin's machine. The fire that generated the steam was underneath the metal plate that formed the base of the cylinder, and in order to condense the steam, so that the piston might descend, it was necessary to take the fire away from the plate and to let the cylinder cool. Then, after the descent was accomplished, fresh steam was generated, and a counterbalancing weight lifted the piston to its original position.

Nevertheless, this embodied the first germ of the condensing steam engine, but so utterly impracticable in character that it must have perished in its birth if practical mechanics had not taken it in hand.

Newcomen's Engines. Newcomen and Cawley took up this engine in 1705—after a lapse of 15 years—and, still effecting the descent of the piston by atmospheric pressure and its ascent by a counterpoise, they adopted the more simple and speedy method of refrigerating the steam by introducing cold water round a space contained between the outer surface of the steam cylinder and the inner surface of an enveloping cylinder. Still, this was a slow process, and, though a very great step in advance, would have been insufficient to bring the engine into general use. But luckily, through want of suitable tools, the cylinder could not be bored, and the piston therefore could not be made steam-tight. As a clumsy remedy, a stratum of water was kept above the piston to fill up the open spaces between its circumference and the sides of the cylinder. One of these pistons was observed accidentally to be travelling more rapidly than usual, and on examining into the cause of this increase of speed it was found that water was dropping down the badly-fitted sides and condensing the steam underneath. The hint was taken, and water henceforth was thrown *into* the cylinder instead of *around* it.

Newcomen's pumping engines were all driven by the pressure of the atmosphere upon the upper side of a piston in a cylinder open at the top. A substantial improvement in these was made in producing the steam in a vessel or boiler away from the cylinder, and leading it thence to the latter through a pipe. Time, of course, was saved thereby, but the steam had still to be condensed within the cylinder after having done its work, in order that the pressure of the atmosphere might operate above the piston against the vacuum formed beneath. The atmosphere pressure amounted, of course, to a considerable total over the area of a piston of several feet in diameter, and all these engines were therefore of very large bore. But as it was necessary to get rid of the counter-pressure of the atmosphere against the lower side of the piston, steam was used as a convenient method of producing a vacuum there. In operating these engines steam was first introduced below the piston, displacing the atmosphere, and then condensed by a spray of cold water. The piston was then pushed down by atmospheric pressure opposed to a vacuum. The piston-rod was attached by a chain to one end of a pivoted beam. A chain at the other end lifted the rod of the mine pump. When the stroke was completed, the weight of the pump-rod, made sufficiently heavy to counterbalance the weight of the piston, pulled the latter up to the top of the cylinder, at the same time that steam was being admitted below the piston. Several of these venerable " fire engines " remain in existence to-day, and some are still in operation.

Watt's Inventions. Crude, and even comical, though the arrangements of the Newcomen engine appear to us, it was the only workable type in use until 1769. One of the oldest of these has been in service at Bedminster, Bristol, nearly until the present time. It was in operation in 1900, and was attended to by a man whose father and grandfather lived and died in the service of the same engine. The only interest which these engines possess now is that they were the primitive types with which Watt was familiar, and the repair of a model of which for Glasgow University—still preserved—led to those researches and inventions by which he designed in nearly all its essentials the modern type of steam engine. The old style of cylinder, with its axis vertical, and the beam were retained; and the functions of the Watt engines were restricted mainly to that of pumping water from mines, thus following the Newcomen engines.

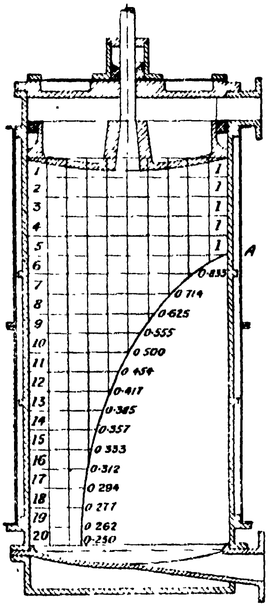
The Separate Condenser. The great and crowning glory of the inventive genius of Watt consisted in an improvement which it is difficult for us in the present day to appreciate fully. It was one of those apparently very trifling improvements which have been fraught with immense consequences. It consisted merely in condensing the steam in a vessel *away* from the cylinder. Watt invented much more, improved in many other ways, but that is the bottom fact in his life's work. So simple was it that his patent was attacked and infringed because of its simplicity, yet so rich in results that it became the basis of wealth to Watt and his partner Boulton, and to many others beside. It gave the death-blow to the old water-wheels and windmills, became a powerful factor in the extinction of the domestic system of manufacture, and in the enormous growth of the factory system, and rendered steam navigation possible. Yet it was merely a vessel for condensation, separate from the cylinder, nothing more.

In the words of the historic patent of January 5th, 1769, " In engines that are to be worked wholly or partially by condensation of steam, the steam is to be condensed in vessels distinct from the steam vessels or cylinders, although occasionally communicating with them ; these vessels I call ' Condensers.' " Men's minds run in grooves, out of which only the genius of the great inventors lead them. For a century men had condensed the steam within the cylinder, and only after years of wearing thought and frightful headaches did Watt evolve the idea of the separate condenser, and he tells in one of his letters how the idea came to him while walking one Sunday on the Green of Glasgow. It seems now almost incredible that previous to this more than three-fourths of the steam generated was wasted in condensation in the cylinders, for which there was no remedy until the idea of separate condensation flashed across the mind of Watt. Condensers are used for all engines except those of the locomotive type, and some of the smaller high pressure kinds, jet condensers in many cases, and surface or tubular condensers for marine engines.

The First Steam Engine. Watt also made the first steam engine when he employed the elastic force of steam in place of that of the atmosphere to push the piston down, still, however, creating a vacuum below it by the condensation of steam. This was Watt's *single-acting* engine. Afterwards (1784) he made the first *double-acting* engine, by employing steam pressure alternately on each side of the piston, creating at the same time a vacuum on the side opposite to that against which the pressure was exercised. Thus, the extra weight on one end of the beam required to raise the piston up was abandoned.

The Steam Jacket. Watt applied the first steam jacket, for he clearly understood that the "steam vessel" (the cylinder) must be kept as hot as the steam that enters it, by enclosing it in non-conducting materials, or by surrounding it with steam, or by not allowing water or any other substance colder than steam to enter or come in contact with it. The way to do it was by no means apparent at once. One curious attempt was the following: He observed by experiments with a small model that the cylinder condensation was greater than in an actual engine, and that suggested to him the making of cylinders of bad conduction, wood for example. He made one, therefore, in wood, with a 6-in. bore, and 12-in. stroke, soaked in linseed oil, and baked. This did not answer to his liking.

Other Improvements. He also applied the air-pump to draw out any air present in the condenser, and which would impede the working of the engine. He cut off the steam at part stroke, causing it to work expansively, and took indicator diagrams. Figure 2 is a diagram which formed a portion of Watt's patent of 1782, in which the expansive action of steam is illustrated. The description is too lengthy for quotation, but the diagram shows that steam at atmospheric pressure is admitted to the upper side of the piston for a length of 2 ft. to the point A, in a cylinder 8 ft. in length, and then cut off. The figures in the curve of expansion represent the gradually diminishing pressure of the steam until it reaches the point of exhaustion at 20, where it is one-fourth of the initial pressure. The jacket around the cylinder will be noticed, and also the general arrangements of inlet and exhaust passages, covers, stuffing-box, piston, with its junk ring, all of which look odd by comparison with present practice.

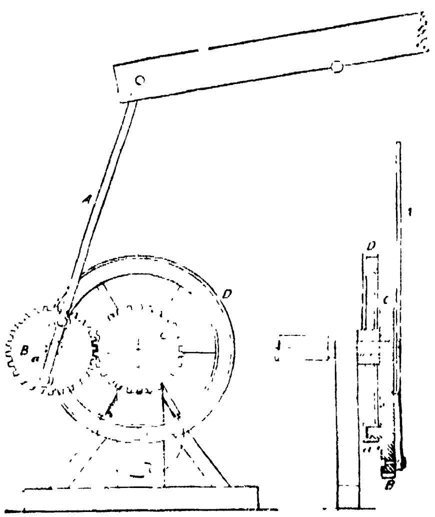


2. PRESSURE OF STEAM IN A CYLINDER

He effected improvements in the automatic working of valves, applied parallel motions in place of the chain at the arch head of the old beams, invented the " centrifugal regulator," or governor, used oils in place of water for lubrication, and designed glands and stuffing-boxes, all of which are embodied and vastly developed in present-day practice.

The First Rotative Engine. But up to 1781 no Watt engine had been made rotative. There was reciprocating motion only; the piston, moving downwards, dragged the pump-rod upwards, and vice versâ. Of course, the crank was known, being as old as the lathe, but its application to the steam engine had already been patented, and so when Watt desired to make rotative engines he devised the famous *sun and planet motion* [8]. This was one only out of half a dozen devices with the same object which were born in his inventive mind. He would have used the crank, but that his rival Hornblower had patented its application to steam engines. The sun and planet motion is only a mechanical curiosity now. But it must be remembered that before the time of Watt the necessity for rotative engines had not arisen. Almost all the old engines were used for pumping water out of mines: the long rods, or *spears*, were just attached directly to one end of the great beam, and partook of its up and down motion.

It was in 1781 that Watt took out the patent for converting the reciprocating into rotary motion to the wheels of mills or other machines by means of the sun and planet motion, an ingenious device long since superseded by the crank. An engine fitted thus [3] is at South Kensington. The place of the pump rod at the end of the beam was taken by a connecting rod, A, at the lower end of which a cog-wheel, B (the planet wheel), was fixed, so that it could not turn. Its teeth engaged with those of another wheel, C, a sun wheel, fixed on the shaft of the wheel D, free to rotate and made to rotate by the movement of the planet wheel around it. A pin, *a*, projecting from the back of the planet wheel, and guided by a groove in D maintained the toothed wheels in contact. Later came the crank as we now know it, and with this last improvement Watt left the beam engine essentially as it exists to-day. Watt and his partner Boulton made engines for the mines, and for flour mills, and founded the Soho works near Birmingham, which, remodelled, still remain in existence.



3. DIAGRAM OF WATT'S STEAM ENGINE

The Oldest Steam Engine in the World. This [4] is one of the first two constructed by James Watt, in 1776. It remained in regular service from that period till 1898, a period of 122 years. It was built to the order of the Birmingham Canal Navigations, and was removed in 1898 and re-erected at the Ocker Hill Pumping Station, to be preserved as a priceless relic of early engineering. The cylinder of this engine is 32 in. diameter, and the piston has a stroke of 8 ft. It has the old arch head, and chains at each end of a wooden beam, and antedates Watt's famous invention of the sun and planet motion, the parallel motion, and the governor. This venerable relic must have been familiar not only to Watt and his partner Boulton, but to his great contemporaries, Rennie, Telford, Smeaton, and Murdoch. An interesting incident is, that when this engine was superannuated in 1898, the Birmingham Canal Navigations gave the order for the new engine to take its place to the firm James Watt & Co., of Soho, the successors to the original firm, who began business in 1774. These new engines, erected at the Walsall pumping station are up-to-date in all respects, are of vertical type, triple expansion, of 240-horse power, and have a pumping capacity of 12,713,600 gallons per day. Over 500 pumping stations have been supplied with engines from Soho.

4. THE OLDEST STEAM ENGINE IN THE WORLD

Watt Engines and Modern Engines. The engine as James Watt left it, though deemed a giant at that period, was nevertheless an overgrown, heavy weakling, clumsy in its movements, and terribly wasteful in its steam consumption. Comparing the engines of to-day with the best of a hundred years ago, we find that from six to eight times the quantity of coal which is burnt now would have to be burnt if the old engines had survived. The annual coal bill for large mill engines, railway locomotives, and marine engines now runs into enormous figures. If these sums had to be multiplied by from six to eight times, the cost would be prohibitive, and the economic reactions on society would be difficult to forecast.

Readers will be able to appreciate the following comparisons between the old engines and those which embody the best designs to-day. The patriarchal engines often broke down, required constant attendance, and though so massive, they suffered from constitutional weakness; they were asthmatic, wheezy, uncertain in action, huge giants who, consuming vast quantities of coal and water, gave little in return. In May, 1775, Mr. Boulton wrote to James Watt about a new engine which the firm were building: "The engine goes marvellously bad. It made eight strokes per minute, but upon Joseph's endeavouring to mend it, it stood still. Nor do I at present see sufficient cause for its dulness." In 1782, Watt, writing of a Cornish engine by Hornblower, said: "When they have got a very strong steam it will make twenty-one strokes in three minutes, but then comes to rest, and must stand five minutes before it gets strength enough to make another stroke, and all the while they must fire away as hard as ever they can, otherwise it will not work at all."

Now there are many engines to-day of which it is literally true that they might be started and left to run for a year without being touched by the attendant. The engines of a liner continue working during the whole of the voyage from port to port. Engines for electric lighting continue in motion for many months in succession. The fact that a locomotive makes a run of from 100 miles to 200 miles without a stoppage is considered marvellous. But that, though rather remarkable, is fairly eclipsed by some colliery engines, and engines employed in electro-deposition, which are stopped only once a year, while blast engines run for even longer periods.

Engine Power. Vast power is exerted by the modern engines. A horse power is equivalent to the lifting of 33,000 lb. 1 ft. high per minute, or 1,980,000 lb. lifted 1 ft. high per hour. A 50-horse power engine was a giant a century ago. At the present time the myriads of spindles in the large cotton mills are driven by engines the power of which ranges from 1,000-horse power to 3,000-horse power, or even 4,000-horse power. One particular set of engines of 3,000-horse power in a mill in Bombay weighs 520 tons, the big rope driving-wheel, 124 tons. Eight boilers, 7 ft. 6 in. in diameter and 28 ft. long, are kept constantly going to supply steam to these gargantuan engines, at a pressure of 180 lb. per square inch. They consume 24 tons of coal in the day's work. Yet 1¼ lb. of coal yield a horse power for an hour. If these engines were so wasteful as those at the beginning of the century they would consume about 160 tons in the day's work. The engines of a liner such as the Campania do the work of 30,000 horses. A locomotive engine is a mite beside these, for its strength is only equal to 800 or 1,000 horses. The firm of James Watt & Co., of Soho, were naturally the principal makers of marine engines during the earlier period of their development. Though up to 1854 the firm had manufactured in all 319 marine engines of an aggregate 17,438 nominal horse power, or 52,314 actual horse power, yet in the 79 years thus covered the total horse power was not equal to that of the combined engines of the Campania and Lucania, or of the engines of one of the new Cunarders, the Lusitania or the Mauritania.

Moreover, at the end of the eighteenth century it was impossible to bore a cylinder true. No machine was in existence which would plane or shape or slot metal. There was no true master screw in existence. The elements of the self-acting lathe had only just been put on a practical basis by Maudslay. There was no method of measurement which was precise and reliable.

The Boilers. But these truly magnificent engines are, after all, only means for the utilisation of heat. Behind these are the essential boilers in which the necessary heat is generated in the form of gaseous steam. The history of the growth of the steam boiler is fully as interesting as that of the engines, though to the general reader it is a sealed book. Here are some leading facts. In the time of Watt the pressure of steam did not exceed from 4 lb. to 6 lb. on the square inch, and there were no tubes for increasing the efficiency or heating surface. To-day, pressures of 60 lb. and 80 lb. are low. Locomotives are worked to 150 lb. and 160 lb., marine boilers to 180 lb. and 190 lb., while the water-tube boilers are worked easily to 250 lb. The early boilers were of cast iron, sheet iron, and even of wood. There are few boilers now which are not made of steel.

At that time, Great Britain had accomplished little in the manufacture of wrought or bar iron. The fact now seems scarcely credible that during the period in which Watt had been improving the steam engine, and Hargreaves, Arkwright, Crompton, and Cartwright inventing their wonderful machines, the country should have been dependent upon America, Russia, and Sweden for bar iron. Not till 1784 had Henry Cort perfected the system of puddling and rolling for the production of malleable iron. Though high pressures were necessary fully to develop the power of the new motor, boilers could not be made to endure them. When the eighteenth century closed there were no Cornish or Lancashire boilers in existence, no multitubular marine, or "Scotch" boilers, no multitubular boilers of any kind working commercially, no boilers of steel, very few of wrought iron. The horizontal boiler of the egg-ended type was beginning to be built about 1800, previous to which the waggon boilers had been used. Those were the days of cast-iron boilers, and very low pressures. Power was secured by using large cylinders. Mechanical stoking, though patented, was as yet impracticable

Without the multitubular boiler, neither the locomotive nor the ocean steamships could have been possible. Yet in spite of increased pressures, which, like high speeds, long alarmed timid people, the boiler to-day is vastly safer than the weakling of the early half of the last century. The records of our well-cared-for locomotives and steamships show that the highest pressures are absolutely safe. In fact, an explosion now can never be due to accident or to any mysterious cause. It is wholly preventable, and when it happens is due to neglect, and this is the proper view which the Commissioner to the Board of Trade enforces by fines.

Later Developments. Meanwhile, a race of engineers had arisen, contemporaries and successors of Watt, whose work has left permanent results. The idea of using two cylinders, high and low pressures, for the expansion of steam was advocated by Hornblower in 1781. Later, Woolf, and then McNaught, adopted the same principle, whence the modern compound engine has developed. The principle is commonly applied to land and marine engines, and now rather extensively to locomotives. Its highest development is in the marine engine. But not until 1869 did compound (two-cylinder) engines begin to displace single cylinder engines on the ocean liners of the Atlantic, nor triple expansion engines till 1884.

The modifications made in the steam engine to qualify it for special services will be illustrated in this course. They include the factory, and the high speed central station types; the marine and locomotive, and the rotary engines, including the steam turbines. There are also the internal combustion engines, using gas of various kinds, and oil, in which great developments have been made during the last half-dozen years. Afterwards the generators, the boilers will be considered.

TECHNICAL DRAWING

continued from page 5352

By Professor R. ELSEY SMITH

DRAWING is the chief medium through which the architect expresses his intentions, not only to his clients but to the contractors, and to the various tradesmen whose work it is one of his duties to direct and supervise.

Instruction in the art of drawing is an important part of an architect's education, and it is essential to his entire success in his profession that this should be thorough and complete. In the early stages of this instruction the student must acquire a knowledge of the construction and use of scales, and a mastery over the instruments which are necessary to enable him to make drawings accurately to scale.

Scales. The student is recommended to read carefully the introductory remarks upon Engineering Drawing on pages 2788-9, with reference to scales and instruments. For certain purposes, architects use a scale of $\frac{1}{16}$ in. = 1 ft., or $\frac{1}{192}$ full size; the other scales in ordinary use are $\frac{1}{8}$ in., $\frac{1}{4}$ in., $\frac{1}{2}$ in., 1 in., $1\frac{1}{2}$ in., or 3 in. = 1 ft. Occasionally other scales are used, such as $\frac{1}{12}$ in. or $\frac{3}{8}$ in. = 1 ft., but they are less convenient.

For laying down block plans of sites for submitting to local authorities, a scale of $\frac{1}{22}$ in. = 1 ft. is often required, which is equivalent to 3 in. = 1 chain; and for laying down plans of large estates $\frac{1}{33}$ in. and $\frac{1}{66}$ in. = 1 ft. are also used.

1. SCALE OF FEET

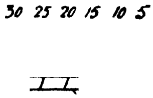
2. SCALE OF FEET AND INCHES

Architects use both open divided scales and fully divided scales; the latter are particularly serviceable in the case of scales of $\frac{1}{2}$ in. = 1 ft. and upwards. It is of the utmost importance that a scale should be divided with the greatest accuracy, as any irregularity will be reproduced in every drawing made with it. The scale is usually divided on both edges, and the same scale may be indicated on both, or two separate scales may be shown, such as $\frac{1}{8}$ in. and $\frac{1}{2}$ in. = 1 foot.

Delineating Scales. It is very desirable that every drawing, except those drawn full size, should have the scale to which they are made drawn upon them, and not merely described in words. This enables any dimension to be read off, with the help of a pair of dividers. In contructing such a scale on paper, the boxwood or ivory scale may be used for marking off on this paper the main divisions, but subdivisions should be redivided with a pair of spring bows to ensure accuracy. Such a scale is usually arranged as an open divided scale. A scale that is intended for reading long dimensions in feet should be divided so that the point 0 lies between the part of the scale divided into multiples of a foot and the part divided into multiples of 10 ft [1]; but it is sometimes drawn with the 0 at the extreme left hand of the scale, and the first 10 ft. only subdivided; this leads to confusion in reading off dimensions, but would be correct if the scale were fully divided. In the same way, where a scale is required for reading feet and inches, the 0 should be placed between the part of the scale divided into inches and the part divided into feet [2].

How to Make an Accurate Scale. Where dividers are used for setting out a scale on paper, it is not sufficiently accurate to set the dividers so as to correspond with a single division on the standard scale, and set out the scale from this unit; for if there is any error in taking off the dimension, this, which may be inappreciable in a single unit, may become serious if repeatedly multiplied. The whole length of the scale, or at least a long length, should be first marked on the paper, and then subdivided. For example, if a scale of $\frac{1}{8}$ in. to a foot to read 60 ft. is to be drawn, the length required for 50 ft., which is $6\frac{1}{4}$ in., is accurately marked by means of a scale or rule, and is subdivided into 5 equal parts, and marked from 0 to 50; an additional length equal to 1 part, which is 10 ft., is marked off to the left of the 0, and subdivided into 10 parts, or feet. Even with the greatest care there may be a very trifling error between the exact length of successive feet, owing to irregularities on the paper and the thickness of the dividing lines; but such an error, if it exists, will not materially affect the accuracy of a long dimension.

The Scale with Minute Divisions. Where the parts into which a scale is to be divided are so minute as to make it impracticable to indicate them side by side in a single line, a scale may be made by using several additional parallel lines exactly equidistant [3]. The number employed must be selected so that it will exactly divide into the number of subdivisions required; the quotient resulting from this division gives the number of parts into which the top and bottom lines are divided. Diagonal lines are drawn from one division in the top line to the next division in the bottom line intersecting the intermediate ones.



3. METHOD OF DIVIDING A SCALE MINUTELY

As an example: If a line $\frac{3}{4}$ in. in length is required to be divided into 30 subdivisions, there would be more than can be conveniently shown on a single line [8]. If five additional lines be drawn $\frac{30}{5} = 6$, and the top and bottom lines are subdivided into six equal parts, and the diagonals drawn, the first diagonal cuts the line *a* at a distance equal to 1 part from the end of the scale, the line *b* at a distance equal to 2 parts, *c* at 3 parts, *d* at 4 parts, *e* at 5 parts, so that any of these may be read off. In the same way, by using the correct line, any number of parts between 5 and 10, 10 and 15, and so on, may be scaled off.

Beyond the preparation of drawings of a geometrical character to scale, the accomplished architect must acquire facility in freehand drawing from the round, including some knowledge of drawing from the human figure, and must also be acquainted with perspective drawing. These subjects have been already dealt with in previous articles.

Drawing-boards. For much architectural work drawings may be made on paper of imperial size and an imperial board is largely used, and is more handy than the double-elephant size. Occasionally, for large plans, the size known as antiquarian, 53 in. by 31 in., is necessary, but it is unwieldy. The best boards are of pine, with mahogany battens at the back, secured by screws in slots, to prevent warping. One edge is provided with an ebony strip, against which the T-square works.

T-squares are used to draw parallel horizontal lines across a board. They have a thick cross-piece forming the head, one side of which works against the edge of the drawing-board. In the best squares this edge is also formed of ebony. The blade is secured to the head by screws and ebony dowels, so as to be at right angles to it, and is long enough to extend the full width of the board. This also in the best T-squares, which are made of mahogany, has the working edge of ebony, but the cheaper form of T-squares are usually made wholly of pear-wood.

Set-squares. Set-squares are triangles of which one angle is a right angle, and they are used for drawing parallel vertical lines; the lower edge works upon the edge of the T-square, which is held firmly in position against the edge of the board. The upright edge of the set-square will always be truly vertical. The third side is inclined at an angle with the other two. The square is usually made so that the angles between the inclined and vertical sides are each 45°, or are 60° and 30° respectively. Sometimes squares are made to give angles of 50° and 40°, and a square having angles of 63½° and 26½° is also serviceable. The latter is the angle of a quarter-pitch roof, and the former is the angle of the *diagonal line*, by which the height of the back portions of a building are regulated by the London Building Act, and the vertical side of such a square equals twice the length of its base. By shifting the position of the T-square, lines may be drawn parallel to each other with the assistance of a set-square, no matter what angle they make with the horizontal. Set-squares are made of thin, triangular pieces of pear-wood, vulcanite, or celluloid, with a hole perforated near their centre by which they may be hung up. They are also made in mahogany, not solid, but framed of three strips, the centre being open; the edges of these are bevelled, and formed of ebony.

Drawing Paper. Drawing paper may be obtained of various sizes, thickness, and quality for various purposes. Cartridge paper of a buff colour and rather absorbent is used for details and preliminary and rough sketches, but cannot be relied on to take colour well nor to stand much hard wear. A thin, tough detail paper may be used in the same way. For drawings to be finished in pen and ink and colour and for all drawings in which much work is required, a better class of paper is required. For pen and ink work, Whatman's "hot-pressed" and Joynson's "smooth" are suitable, and for colour work, Whatman's "not hot-pressed" and Joynson's "cold pressed." These papers are supplied in sheets imperial size 30 in. by 22 in.; double elephant, 40 in. by 27 in.; antiquarian, 53 in. by 31 in.; and in continuous rolls of 50 yd. long, 30 in., 40 in., 54 in., or 60 in. wide. Numerous other drawing papers are on the market.

Tracing Paper and Tracing Cloth. Tracing paper may also be obtained in standard-sized sheets or in continuous rolls. Such paper, if it is to be used for working out pencil drawings, or if it is to be subjected to hard wear in a building or in a workshop, must be tough; it must also be transparent, so as to allow of any drawing over which it is placed being readily discerned for tracing. This is also necessary if it is to be used as a negative for reproducing by a sun-copying process.

Tracing cloth is made from fine linen rendered transparent, and is tougher and more reliable than tracing paper, but, on the other hand, is less transparent, and if coloured is liable to shrink unevenly. It has usually one side highly glazed, the other side dull. The latter is usually used for drawing upon, the former for colour. This cloth does not take either ink or colour very readily, and should be rubbed over with a little powdered chalk before drawing, which makes the ink take better; the drawing should be tightly pinned to the board when colour is applied. A little ox-gall may be mixed with the colours.

Pencils and Indian Ink. Lead pencils are used in making all drawings. They vary much in intensity of blackness, the range from very hard to soft being H.H.H., H.H., H, F., H.B., B., B.B., B.B.B., but pencils marked with the same letters differ somewhat with different makers. Drawings to ½-in. scale and upwards are often finished in pencil, but drawings to a smaller scale are finished in Indian ink. This may be obtained in sticks, and is then rubbed up in a palette with a little water as required until quite black, or it may be obtained in a liquid form in bottles ready for use. It is important that the ink used should be quite black and opaque, especially if the drawing or tracing is to be reproduced so as to secure a good print. It is also important to secure an ink that, when once dried, will not wash up when colour is spread over it.

It is the general custom among architects to use a rather thick, bold line, but the scale of the drawing must to some extent regulate this. Lines must be well drawn, of even thickness, and carried well up to all angles, and in some styles of drawing they are run a little beyond the angles.

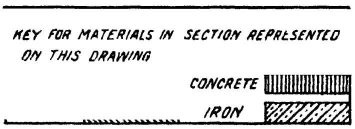
Lines are sometimes formed by a series of dots, where the work indicated by the line is not in such a position that it would really show upon the drawing, but it is nevertheless desirable to represent it. Lines indicating dimensions may be shown by very fine or by dotted lines, or with red or blue ink, and drains are also often represented in *red* ink for soil drains, and *blue* ink for rainwater drains. Brown ink is occasionally used for making drawings in place of black ink.

Colouring Drawings. Most geometrical drawings are coloured conventionally—*i.e.*, no attempt is made in colouring to represent the real appearance of the building, but the colours are used according to a definite scheme in which certain colours represent certain materials; but drawings in elevation, especially if they are to be shown to the client, are often coloured to correspond as nearly as may be to the colouring of the materials employed.

The following schedule gives a list of several of the more important materials used in building, and the colours generally employed to represent them in elevation and in plan or section; but while the colouring is conventional, there is still room for the exercise of a good deal of taste in selecting the exact tints which are to be applied to any set of drawings.

Brickwork built in mortar	Light red, or Venetian red, or crimson lake, light wash	Same colours used darker
Brickwork built in cement	As above	Purple
Stone	Yellow ochre, pale or left white	Indigo
Wood (unwrought)	Indian yellow, pale ..	Burnt sienna
Wood (wrought)	Sepia or Vandyke brown	The same colours, darker
Plaster	Yellow or green, pale..	Blue-grey
Cement floors ..	Grey	The same colour, darker
Ironwork	Prussian blue, light ..	The same colour. dark
Concrete	Payne's grey, light ..	The same colour, dark
Leadwork or zincwork	Bluish green	The same, darker
Copper	Green	Orange
Slates	Greenish grey	The same colour, dark
Tiles	Purplish red	The same colour, dark
Glass in windows ..	Grey or lampblack, light	In details Hooker's green

Hatching on Black and White Drawings. Drawings that are to be reproduced in black and white, such as those illustrating this article, cannot be coloured, and where the main walls are uniformly of one material they may be blacked in solidly, or where two or more materials are used, these may be indicated by the use of *hatching*—that is to say, a series of parallel strokes close together, either uniform in quality but differing in direction, or varied in quality. Examples of these are shown in **4**, and their use will be further illustrated in the succeeding article dealing with details. No variation can be made in elevation work to indicate the materials used except so far as this can be indicated by joint lines, and therefore notes as to materials must be more copious. This method is rarely used for ordinary working drawings. Each drawing should have a key to explain the system used, as shown in **4**.



4. METHODS OF HATCHING

Drawings must be cleaned before colouring, and unless the ink is quite fast, should be washed over with clean water and dried off with clean blotting paper. Large washes should be laid on with a large brush full of colour, care being taken to see that an ample amount of colour is ready to complete the wash. Where two colours are combined to form a tint the mixed colour should be constantly stirred to prevent them from separating. If erasures have been made in the drawing, the colour will be soaked up and a dark patch formed; this may be prevented by using a piece of clean blotting paper, with which the spot is lightly touched and the excess of colour taken up.

Preliminary Sketches. In preparing a set of drawings for a building, especially if it is of a considerable size, it is usual to make the earliest sketches to a small scale, say $\frac{1}{16}$ in. to 1 ft. This enables the general disposition to be worked out with considerable accuracy, and makes the drawings more manageable than if they were drawn at once to a larger scale. A beginning is made with the plans, on which the accommodation required must be arranged and re-arranged to secure convenience of access between the various parts, suitable aspects and compliance with the requirements of the client; but from the first the effect of the plan upon the elevation must not be lost sight of, and these and the sections must be prepared before any final settlement of the plan is made. It is very desirable also at an early stage to make at least a rough perspective view of the proposed building, from which the grouping and arrangement of the masses may be judged. Where such sketch plans are prepared on paper, it is often desirable to keep a record on tracing paper of any arrangement of a plan or elevation that seems to give satisfactory results, even though it may seem desirable to seek for an alternative one. It is useful for comparison and may contain some point which may be embodied in another scheme, or it may in some cases prove, after all, to be the best solution.

The preliminary drawings may be carefully finished in pencil or ink, and coloured and submitted to the client for consideration, and, when approved, possibly after being modified, they form the groundwork for the general drawings.

MEDICINE AS A PROFESSION

The Medical Profession as a Career. Its Branches. Examinations and Study. Private Practice. Army and Navy Services. The Specialist

THE MEDICAL PROFESSION

IT is undoubtedly a mistake for a boy to be forced into the medical profession against his will. The preparatory study is arduous, the duties are exacting, and, to those not interested in it, the work may be repulsive. On the other hand, the blending of human with scientific interests makes it fascinating to many. But, as the "Lancet" says, "if only lads who feel an overwhelming call to heal the sick be regarded as fit and proper aspirants to the practice of medicine then we should at once have our schools deprived of hundreds of young men of the best sort." With many such, though the preliminary steps may seem tedious, interest awakens with increasing knowledge, for "as the mysteries of medicine become clearer their labours will become more absorbing."

The chief requirements are great industry, good average ability, good health, the gift of getting on with people, and moderate capital; and of these, perhaps, the greatest is industry. Brilliant talents will naturally help, but they cannot replace systematic study; the steady student makes the "safe" doctor.

The Medical Student. To become a student of medicine it is necessary to pass a preliminary examination [see Schedule].

Before entering for this the student should decide if he intends to try for a University degree, because in that case he must select the examination held by the University at which he wishes ultimately to graduate. If he means to be satisfied with the diplomas M.R.C.S., L.R.C.P. (Member of the Royal College of Surgeons of England and Licentiate of the Royal College of Physicians, London), he will find the one held by the College of Preceptors the simplest of these examinations. The Licentiate of the Society of Apothecaries (L.S.A.) is an easier diploma to obtain, but its status is not nearly so good.

The Schedule of Examinations at the Universities of Oxford and Cambridge is similar to the one given on the next page, but the degree of M.D. is given for a thesis and not by examination. The fees are rather higher.

The student should enter a medical school attached to a hospital. It is outside the scope of this course to recommend individual schools. Such is the loyalty of a medical man to his old school that he will almost invariably be found to recommend his own if his opinion be sought. The chief points to look at are the facilities offered for the practical study of disease, the character of the teaching provided, and the general reputation of the school. We shall speak here chiefly of the schools in London; but with minor differences the facts will apply to the Scotch, Irish, and provincial schools.

Entering the School. In order to enter a school the intending student should call on the Dean or Warden, bringing with him a certificate showing him to have passed the preliminary examination and a certificate of birth. He then pays the entrance fee and signs the register of students, promising to conform to the rules and regulations of the hospital and medical school. He receives a certificate of having begun medical study. The best time for doing this is at the beginning of a session—in April or October.

The candidate should register himself as a medical student at the offices of the General Medical Council, 299, Oxford Street, W. Strictly speaking, this is not necessary, but it is so simple and convenient a way of proving his status that it should be done. The student has only to send the certificate given him by the Dean and he receives a copy of the entry in the register, which he should keep. There is no fee for this.

The minimum time of study required is five years, but it must be remembered that this does not take into account any loss of time from failure to pass any part of the examinations, or for the extra time required for the higher degrees. The student may be surprised to find that for the first two years he is not taught any medicine or surgery, but only the sciences introductory to them. The course of study is divided into three main periods, each ending with an examination. We will suppose, in the first instance, that he is preparing for the diplomas M.R.C.S., L.R.C.P., and afterwards describe the additional courses required by more ambitious students. The first time each subject is mentioned the title of the most suitable book for its study will be given in brackets. The time will be spent in this way.

The Course of Study. The first year will be devoted to preliminary scientific subjects—chemistry, physics, and biology. Supposing the student to enter, as is most usual, in October, he will have to attend lectures and practical work in chemistry (Luff's "Chemistry." Cassell. 7s. 6d.) and lectures on physics (Corbin and Stewart's "Handbook of Physics and Chemistry." Churchill. 6s. 6d.). Some previous knowledge of chemistry, such as is given in many schools to-day, will be a considerable help and will enable the student to employ more of his time in the more medical subjects. He will also attend lectures and practical work in biology (Mitchell's "Outlines of Biology." Methuen. 6s.). He will begin the study of anatomy by learning the bones of the body, and then pass on to dissection (Cunningham's "Practical Anatomy." 2 vols. Pentland. 23s.). For this he will require a set of dissecting instruments costing about £1; and it will be well if he can buy a set of bones for himself at a cost of from 2½ to 3 guineas. At the end of the winter session, in March, he should pass his examination in biology. During the summer session he will continue to work at chemistry and begin the study of physiology by learning the minute structure of the tissues of the body—*i.e.*, histology (Schäfer's "Essentials of Histology." Longmans. 9s. net.). For this purpose he will need to buy a microscope if he has not already purchased one for his biological work. We recommend Leitz's six-guinea microscope; but in any case it should be one that is capable of having more elaborate lenses added to it later for bacteriological work. To buy a cheap instrument which can never be adapted for advanced work is very false economy. In July the student should be ready to pass his examination in physics and chemistry.

The second year is devoted to intermediate subjects—anatomy, physiology, and pharmacy.

Though the study of anatomy and physiology begins during the first year, it is the second winter session which must be most seriously devoted to these important subjects, which are the very foundations of medical science. Usually there are four lectures in anatomy and three in physiology to be attended each week. Six hours a week will have to be spent in the physiological laboratory, and the remainder of the time (at least 18 hours) must be devoted to dissection.

For this purpose the body is divided into five parts, each student being allotted a part in turn. A charge of 15s. is usually made for each. Meanwhile he is learning from physiology (Starling's "Elements of Human Physiology." Churchill. 12s. 6d.) the way in which the healthy body does its work. He will then be able to appreciate those departures from healthy action which constitute disease.

In the summer of the second year anatomy and physiology should be revised and the study of drugs begun (Hale White's "Materia Medica." Churchill. 7s. 6d. Calvert's "Practical Pharmacy and Prescribing." Lewis. 4s. 6d.). The energetic student may have found time to begin this during his first summer. In July he should pass his examination in anatomy and physiology, and also in pharmacy.

The third, fourth and fifth years are devoted to the final subjects—medicine, surgery, and midwifery.

Study of Disease. Now, the practical study of disease begins. While attending lectures

SCHEDULE OF EXAMINATIONS FOR THE MEDICAL PROFESSION

Time and Place of Examination. Examining Body. Diplomas and Degrees.	SUBJECTS OF EXAMINATION. Subjects that are distinguished under different letters may be passed separately.	Fees and Age Limits for Examinations.
For M.R.C.S., L.R.C.P. Entrance. COLLEGE OF PRECEPTORS.	English. Including Grammar and Composition. Latin. Including Grammar, translation from Latin into English, and from English into Latin. Mathematics, comprising Arithmetic, Algebra, up to easy Quadratic Equations. Geometry—the first three books of Euclid, with easy deductions. Greek, or a modern language. (The following examination certificates are accepted in lieu of this examination : University of London : Matriculation. University of Oxford : Responsions, Moderations, or local examinations. University of Cambridge : Previous or Local Examinations.)	£1 5s.
COLLEGES OF PHYSICIANS AND SURGEONS. Jan., April, July, Oct., First examination.	(*a*) Chemistry and Physics. (*b*) Biology.	£10 10s. For re-examination, £3 3s. for (*a*) ; £2 2s. for (*b*).
Second examination.	(*a*) Anatomy and Physiology. (*b*) Pharmacy and Materia Medica.	£10 10s. For re-examiation. £6 6s.
Third examination.	(*a*) Midwifery. (*b*) Surgery. (*c*) Medicine, Forensic Medicine, and Public Health.	£21. For re-examination, in (*a*), £3 3s. ; in (*b*) or (*c*) £5 5s.
For F.R.C.S. ROYAL COLLEGE OF SURGEONS. May and November.		
Primary examination.	Anatomy and Physiology.	£5 5s.
Final examination.	Surgery.	£12 12s. On admission a further fee of £13 13s. (reduced to £3 3s. for those holding M.R.C.S. diploma). 25 years
For M.R.C.P. ROYAL COLLEGE OF PHYSICIANS. Every three months.	Medical Anatomy, Principles and Practice of Medicine, Principles of Public Health, and Psychological Medicine, Translation from Latin, and either French, German, or Greek.	£6 6s. for examination, £3F 14s. on admission, reduced to £10 10s. for Licentiates.
For M.B., B.S. UNIVERSITY OF LONDON. 1. Matriculation. Jan., June, Sept.	English, Elementary Mathematics, Latin or Elementary Mechanics, or Elementary Physics, or Elementary Chemistry, or Elementary Botany. Two optional subjects, selected from Languages, History, Logic, Physical and General Geography, Natural Sciences.	£2 16 years
2. Preliminary Scientific. Jan. and July.	(*a*) Inorganic Chemistry and Physics. (*b*) Biology. (*c*) Organic Chemistry.	£5
3. Intermediate. Jan. and July.	(*a*) Anatomy and Physiology. (*b*) Pharmacology.	£10
4. Final. Oct. and May.	(*a*) Medicine, General Pathology, Forensic Medicine, and Hygiene. (*b*) Surgery, Midwifery, and Diseases of Women.	£10 For re-examination, £5. 21 years
M.D. Dec. and July.	One of the following subjects : Medicine, Pathology, Mental Diseases, Midwifery and Diseases of Women, State Medicine.	£20 25 years
M.S. Dec. and July.	Surgery, Surgical Pathology and Anatomy, Operative Surgery.	£20 25 years

on medicine (Osler's "Principles and Practice of Medicine." Appleton. 18s. net; or Taylor's "Manual of the Practice of Medicine." Churchill. 16s.) and surgery (Walsham and Spencer's "Theory and Practice of Surgery." Churchill. 15s.) the student starts as a "dresser." Under the direction of his house surgeon he attends to the multitude of smaller accidents and surgical ailments with which the out-patient room is crowded. Later he attends in the same way to the more serious cases in the surgical wards, and assists in a minor capacity at operations.

During this time he is attached to the service of one of the visiting surgeons, to whom he must make himself useful in every way he can. The student is usually allowed to select the "chief" under whom he will serve. A good chief teaches both by example and precept, is regular and systematic in his hospital work, and expects system and regularity in his dressers. The mental stimulus of a group of keen and inquiring students reacts on him, too, keeping him alert and progressive in his methods. To select an easy-going chief may be pleasant to the lazy student, but it is a fatal mistake.

Six months to a year should be spent as a dresser, but not consecutively and not necessarily under the same chief. After the first three or six months of dressing, the student passes over to the medical wards, where he acts as a "clinical clerk" for one of the visiting physicians. Here he occupies a similar relationship to his chief as in the surgical wards. Each physician or surgeon appoints a recently qualified student his resident house physician or house surgeon, who is in charge of the cases between the visits of the chief. It is the ambition of every keen dresser and clerk so to perform his duties as to obtain this position later on.

Midwifery. During his third summer session the student will begin the study of midwifery (Galabin's "Midwifery." Churchill. 15s.) at lectures. When he has completed these, together with one term of dressing and clerking, he attends confinements. Most hospitals have a district where poor women are attended in their own homes. It is an excellent system for both sides—the student has his first real taste of responsibility and the patient gains the services of one well grounded in his duties, who is acting under the supervision of a resident medical officer, for whom he is bound to send in case of any complication. At least 20 cases must be attended by every student, and though this may be done more pleasantly, perhaps, at a lying-in hospital, the student escapes responsibility thereby and loses an insight into the lives of the very poor which is invaluable to every medical man.

By this time the fourth year will have been entered. Of this three months should be spent in the department for the diseases of women (Herman's "Diseases of Women." Cassell. 25s.; Herman's "Difficult Labour." Cassell. 12s. 6d.). A course of tutorial classes is also held, and after that the midwifery part of the Final Examination should be passed.

Concurrently with all this the student will have his energies taxed by attendance at lectures on important branches, like forensic medicine, dealing with medico-legal questions (Husband's "Forensic Medicine." Simpkin. 10s. 6d.); public health (Whitelegge's "Hygiene." Cassell. 7s. 6d.); and pathology (Green's "Pathology." Renshaw. 17s.; Bowlby's "Surgical Pathology." Churchill. 10s. 6d.). Every year the importance of pathology—the study of the processes of disease and their effects on the bodily tissues—increases. The student must lose no opportunity of practical work in this department. He must assist in post-mortem examinations, he must study diseased tissues both in the museum and with the microscope; he must learn to examine the blood and the commoner microbes. No one who neglects pathology can aspire to be up-to-date as a medical man.

Special Studies. The diseases of the eye (Swanzy's "Ophthalmic Surgery." Lewis. 12s. 6d.), the skin (Malcolm Morris's "Diseases of the Skin." Cassell. 10s. 6d.), the throat and ear, and orthopædic surgery will occupy the time until the fifth year has been fairly entered. A fever hospital must be entered for two months (fee, three guineas; for the higher examinations three months' attendance is required—fee four guineas).

The student must also acquire some knowledge of insanity (Savage's "Insanity." Cassell. 9s.) by lectures and by seeing cases at an asylum. He must also take a course of operative surgery (Treves' "Student's Handbook of Surgical Operations." Cassell. 7s. 6d.; Treves' and Keith's "Surgical Anatomy." Cassell. 9s.). The fee for the elementary class is usually one guinea; for the advanced class (for higher examinations) five to seven guineas. A certificate of proficiency in vaccination must be obtained by attendance at a vaccinating station (fee, one guinea). The student should also learn to administer anæsthetics. Such time as remains will be occupied in obtaining experience in the wards and out-patient rooms of the hospital. What he *sees* will be remembered better than what he *reads*. The best method is to read up at night the diseases of which he has seen examples during the day. Revision classes are also held before every examination to refresh the memory. The student should now be in a position to pass the rest of the final examination (medicine and surgery, taken separately or together) and receive his reward by emerging as a fully-qualified medical man.

As soon as he obtains his first qualification, the *medical man* must register himself at the offices of the General Medical Council, no matter whether he previously reported himself as a student or not. The fee is £5. This is essential, as the Medical Register is the official list of the members of the profession. Subsequent qualifications can be registered for a fee of five shillings.

The Higher Examinations. The possession of a University degree is a great help to a medical man. The degrees of the London University necessitate a more prolonged course of study than that described above. The whole of the first year must be spent on the preliminary scientific subjects. Advanced classes in physiology and anatomy must be attended, and a course in organic chemistry is needed. Two years' study will be required for the intermediate examination. The final examination is decidedly harder. The degrees of Doctor of Medicine or Master in Surgery will require about two years' study after taking the degrees M.B., B.S. Students who intend to take degrees at Oxford or Cambridge reside during their first three years at the University and should pass their examination in anatomy and physiology there. They enter a London hospital for the final subjects only, and a proportionally reduced fee is charged. The final examination for the degrees of Bachelor of Medicine and Bachelor of Surgery resembles in essentials that required by the London University. The degree of M.D. is obtained by writing a thesis and not by examination.

The Fellowship of the Royal College of Surgeons (F.R.C.S.) is essential to anyone taking up surgery as a speciality, and is an excellent diploma for anyone to possess in general practice. The subjects of the primary examination are anatomy and physiology; of the final, surgery. Special classes must be attended for these examinations, which are decidedly difficult and notoriously uncertain.

The Membership of the Royal College of Physicians (M.R.C.P.) is essential to anyone intending to practise as a consulting physician, but it is a drawback to general practice. The holder may not buy or sell a practice, may not enter into partnership nor dispense medicines. He is expected not to charge a lower fee than one guinea.

Expenses Incurred. The London hospital fees given in the table below do not include fees for courses in fevers, operative surgery, and vaccination [see above]. Fees in the Scottish, Irish, and provincial schools are somewhat lower.

Beyond expenses incurred for fees, at least £10 a year should be allowed for books and instruments. Backward students may require private tuition from time to time; the fee for a three months' course is 10 guineas. If the student can live at home a great saving naturally results, but the great majority live in lodgings. Several hospitals have residential colleges attached. For the greater part of the course it is not advisable for the student to live in college, however. Change of air and surroundings is preferable. While working for the final examination a short residence in college is profitable because it enables so much emergency and night work to be seen. Many of the teachers receive students to live with them for an average fee of two guineas a week; this ensures a certain amount of supervision. The "Lancet" says: "If a London student is careful and orderly, if he selects rooms in an inexpensive quarter of the metropolis—not always easy to do if his school is placed in the West End of London—if he requires no private coaching, and, if, by industry and ability, he is able to make certain of his examinations as the time comes for them, he can make an allowance of £100 a year for five years support him during his educational career. But his parents or guardians should remember that if he has no need to have recourse to them it is because he has shown considerable self-control and has resolutely turned his back upon many pleasures, which, however innocent, cost the odd shillings that he has never possessed."

HOSPITAL FEES FOR MEDICAL STUDENTS IN LONDON

	Fee	
St. Bartholomew's	£31 10s. entrance fee	
	£31 10s. annual fee	
	or £173 5s.	If paid in one sum
Charing Cross	£132 6s.	If paid in five instalments
	or £120 15s.	If paid in one sum. For the sons of medical men, 115 and 105 guineas respectively
St. George's	£160	In four instalments
	or £150	If paid in one sum
Guy's	£21 entrance fee	
	£31 10s. annual fee	
Kings' College	£148	In four instalments
	or £135	If paid in one sum
London	£136 10s.	If paid in three instalments
	or £126	If paid in one sum. A reduction of 15 guineas to sons of medical men.
St. Mary's	£145	If paid in four instalments
	or £140	If paid in one sum
Middlesex	£152 5s.	If paid in four instalments
	or £141 15s.	If paid in one sum
St. Thomas's	£21 entrance fee	
	£31 10s. annual fee	
University College	£31 10s.	For first examination
	£52 10s.	For second examination
	£84	For third examination
Westminster	£126	If paid in half yearly payments
	or £115 10s.	If paid in one sum
Royal Free (for women students)	£150	If paid in four instalments
	or £140	If paid in one sum

How to Enter Upon Medical Practice. The newly-qualified man has still much to learn. By far the best way of rapidly acquiring experience is to hold the post of house physician, or house surgeon, for six or twelve months at some hospital. It should be the aim of every student to hold one of these posts, for no finer training exists. It stamps a man in a way which the trained observer can generally detect. Living amid his patients he learns to recognise minute hourly changes in their condition, so that in after life he can draw correct conclusions rapidly and confidently. He is responsible for all treatment between the visits of his chief, to whom he can always turn in case of any difficulty. During the time he holds office board and lodging is supplied, and in some cases a small salary is paid.

But hospital practice differs widely from private practice. In the former, everything is organised and ready for all emergencies, the house surgeon having merely to order what he wants. In private practice considerable ingenuity must be shown in improvising arrangements for the sick room, where the orders are not as a rule carried out by trained assistants. Much more tact and diplomacy are required. Delicate family questions come up constantly which the doctor would never have to face in hospital work. And instead of simply doing charitable work, his profession has now to be conducted so as to yield an income.

Without guidance through this maze he may make mistakes that will mar his professional chances. He must remember that, in general, the public are incapable of judging his professional merits, but they can appreciate his bearing and conduct; and they conclude that the latter is the measure of the former. The old system by which the medical student was the apprentice of a doctor had many grave drawbacks which render it quite unsuitable to-day; but it had one advantage, that he learned many of those practical details which cannot be taught in hospitals. The best way of learning these points to-day is to act for a time as a "locum tenens," or as an assistant.

The Locum Tenens. While deputy for a doctor the "locum tenens" lives in his house, receiving board and lodging and a fee of three or four guineas a week. A living can therefore generally be made in this way; but it must be strictly regarded as a temporary expedient; to continue to do this long is not to be commended. It is more instructive to act as "locum tenens" for one member of a partnership. From the remaining partner he can learn much about the method of conducting the practice, and the idiosyncrasies of the patients. He must not be surprised if this partner selects the best work for himself, leaving the residue and the greater part of the night work to the "locum."

If there is no partner it is usual for the "locum" to arrive before the departure of the doctor whose work he is going to do, in order to receive instructions. After that he will be dependent on the dispenser, or even the coachman (both generally well-informed and discreet) for his information, though in some cases the doctor's wife will stay behind to look after things. The "locum tenens" is bound in honour to consider in every way the interests of the doctor he represents. He need not be surprised if some patients refuse to see him; the choice of a medical attendant rests with the patient, and no man can do much good to a sufferer who is unwilling to receive him. He must reflect that when he gets a practice of his own he will not care to have his deputy received too gladly.

Setting up in Private Practice. Many men consider it beneath their dignity to act as an assistant. With the suppression of unqualified assistants by the General Medical Council, however, the position and emoluments of the qualified assistant has improved. If he lives with his principal he will receive from £120 to £150 a year.

For a young man there is a good deal to recommend such a position for a time. He sees practice and gains experience without risk of capital; he is taking no irrevocable step. Some assistantships are held "with a view to partnership." This is a convenient arrangement, allowing the principal and assistant to know one another thoroughly before entering into the more enduring bonds of partnership. An assistant is usually bound by agreement not to practise for himself in the district, except in partnership with his principal. This prevents an unscrupulous assistant from getting an introduction to patients and then subsequently diverting them to himself.

Sooner or later, however, the decisive step must be taken. But without capital this is difficult. The cost of a medical education does not exhaust the expenses incurred in entering the profession. The ordinary methods are three: (1) squatting; (2) buying a practice; (3) partnership.

Squatting. Squatting, as it is euphoniously called, means taking a house in a suitable district, putting up a door-plate, and waiting for practice. In no case should this be expected even to cover expenses in less than three years. It will be seen, therefore, that expenditure of capital is really involved in keeping up an unremunerative house. Moreover, there is a considerable element of risk, for after three years the practice may still be most meagre. A town with a fixed population offers no scope for this method, which should only be attempted in a rapidly-growing district. Without influential introductions the chances are that the practice will be drawn from the poorer classes, who are not nearly so conservative in the matter of medical attendants. Moreover, "undesirables" who have exhausted their credit with the more established practitioners regard the new man as their legitimate prey. The young doctor is delighted with his apparently rapid success until the time comes for settling accounts.

The custom is for the new doctor to call upon his medical neighbours and announce his intention of practising. This is rather an ordeal, for, the demand for doctors being the same whatever the supply, the new-comer can hardly expect an enthusiastic welcome, though, of course, he will have a courteous reception.

There is another method which should be condemned. Occasionally, friendly societies and sick clubs advertise for a doctor to settle in a town as their medical officer. The salary is usually just enough to live upon, and a young man may regard this as forming the nucleus to a practice which he can develop. But the club only adopts this course when it has failed to get the doctors in residence to accept their terms. The terms usually accepted cannot be called extravagant—a penny a week for the head of the family, and less from the other members. This scale is found to yield an average of tenpence a visit, from which the cost of medicine supplied must be deducted. The services rendered are therefore in part charitable. But from time to time the larger tradesmen and employers of labour are found in these clubs expecting treatment on the same terms as artisans and labourers. Refusal to act for a club has generally been based upon this ground. If the resident practitioners object, the club will advertise for a medical officer, the aim being to punish them by importing a rival. If a man accepts such an appointment, he is entirely dependent upon the club officials, who will show him scant consideration. At the same time he cannot expect cordial relationship with his professional colleagues.

Buying a Practice. The best class of practice does not often come into the open market, the contracting parties being introduced through their medical school. An influential member of the visiting staff is asked to recommend a suitable man whose capabilities he knows personally. In this way, a student finds a good reputation at his hospital is a valuable asset, while the vendor gets a man whose personal qualities have been appraised in a way a medical agent is unable to do. This method is, perhaps, more usually employed in obtaining a partner than a successor. In whatever way the introduction has been effected, however, the practice should be investigated by a recognised medical agent, who will go through the books and value it. No objection is raised, as a rule, to this; if it is, negotiations should cease. For, without any fraudulent motive whatever, a vendor may take too roseate a view as to the extent to which the practice is transferable. A death vacancy is of notoriously uncertain value, especially if the preceding illness has been prolonged. During this time, a practice crumbles away surprisingly. In any case, many patients will transfer themselves, not to the new doctor, unknown to them, but to one of the other practitioners already established in the district.

Not more than one year's purchase should be paid for a death vacancy, and the successor should not anticipate holding more than two-thirds of the existing practice.

A much safer plan is where the outgoing practitioner is willing to give his successor an introduction by staying on for six months or so. In this case, about one and a half years' purchase is usually asked.

Partnership. From a pecuniary standpoint, this is undoubtedly the safest plan. It would seem to have other obvious advantages, such as a colleague's assistance on all occasions when requisite, and greater freedom in getting away. Yet in medical practice partnerships seem, as a rule, much less successful than in other walks in life. Perhaps this is because of the intimate personal relationship between doctor and patient into which a third person introduces a disturbing element. Moreover, "partners are not usually equally matched in industry, capacity for work, tact, temperament, and other qualities indispensable to an intimate and congenial fellowship, and are not equally cared for by the public" (Cathell). If one partner does most of the work, he chafes at earning money for the other, while the latter feels jealous of the superior popularity of the former. Whatever the cause, really satisfactory partnerships are unfortunately not common. A higher premium is usually paid for a partnership than for a simple succession, the present price being two to two and a half years' purchase.

The Daily Round. It is usual for the doctor to be at home from 9 to 10 or 10.30 in the morning to see patients; if he has club or parish patients, they should be seen at his surgery then. This gives time for the arrival of messages requesting him to call. The morning round should start not later than 10.30, and should be so arranged as to allow a visit home in the middle of the morning to collect any fresh messages. The necessity for an afternoon round will depend on the size of the practice. The afternoon is usually the time fixed for consultations with other medical men. The doctor should set aside certain hours in the evening for seeing patients at his house. Many patients not confined to their room much prefer this method. The time of the next visit should always be mentioned, and should not be left vague; a little tact will generally discover the wishes of the patient as to frequency of visits, and will avoid the charge either of being neglectful or of undue persistence. It should be made clear that for a special visit—that is, one made out of the morning or afternoon round—a special fee will be charged. In this way much time can be saved, and dislocation of the work avoided. But midwifery will always upset the doctor's calculation. Four-fifths of his night work will be due to this—the greater number of births occurring between midnight and 3 a.m. The fees are much smaller in proportion than for any other professional work. Yet no young man can afford to decline such engagements, as the children become his patients, and thereby practice grows.

The Chances of Success. Sir James Paget found that his first thousand pupils met with the following degrees of success:

Twenty-three had distinguished success—that is, they attained to a leading position in practice or to important public appointments.

Sixty-six had considerable success—that is, they held high positions in the Services, or obtained good provincial or country practices, and enjoyed more than ordinary esteem and influence in society.

Five hundred and seven had fair success—that is, they possessed a practice large enough to maintain them in adequate style, or the tenure of an advancing position in the Services.

One hundred and twenty-four had very limited success—that is, they never attained moderately good practices, but were just able to maintain themselves.

Fifty-six failed. Of these, 15 could not pass their examinations, 10 were dissipated both as students and afterwards, 10 had bad health, and 5 were convicted of misconduct.

Ninety-six discontinued medical studies while still pupils.

Forty-one died during pupilage.

Eighty-seven died within 12 years of beginning practice.

Deducting these last three groups, therefore, 776 actually reached practice, and of these, 596, or rather more than three-quarters, achieved a reasonable degree of success. Later investigations have yielded similar figures. This is an encouraging result; but we must remember that success in practice does not mean the attainment of wealth. We may conclude that to the industrious and well-qualified doctor the medical profession offers a good chance of only an adequate income in return for an arduous but interesting and useful career.

The Doctor's Library. In addition to the books mentioned in the course for the final examination, these will be found very useful:

"A System of Medicine." Clifford Allbutt. Macmillan. 8 vols. £10 net.

"Manual of Medicine." Allchin. Macmillan. 5 vols. £2 net.

"Principles of Treatment." Mitchell Bruce. Pentland. 16s.

"Diseases of the Throat, Nose, and Ear." McBride. Pentland. 25s.

"Diseases of Children." Goodhart & Still. Churchill. 12s. 6d.

"Clinical Methods." Hutchison & Rainy. Cassell. 10s. 6d.

"Food and the Principles of Dietetics." Hutchison. Arnold. 16s. net.

"The Extra Pharmacopœia." Martindale & Westcott. Lewis. 9s. 6d. net.

One of the weekly medical journals should be taken in. Of these, the "Lancet" (7d. weekly) is the best. The "Practitioner" (21s. a year), published monthly, gives excellent reviews of medical progress.

THE DOCTOR ABROAD

One out of every five men qualifying as doctors in Great Britain ultimately comes to practise abroad, usually in the Services or in the Colonies. This does not include the large number who take a temporary post as surgeon on board ship in order to see something of the world before settling down in practice at home. For all these, a course of study at the School of Tropical Medicine in London or Liverpool is essential.

The Doctor in the Navy. Admission to the Naval Medical Service is by examination in medicine, surgery, and allied subjects. Candidates must be between 21 and 28 years of age, of pure European descent, the sons of British parents, of sound constitution and good character, and qualified medical men. Successful candidates receive commissions as surgeons, and study naval hygiene, etc., at Haslar Hospital before proceeding to their station. Pay starts at £225 10s. a year and rises to £657 for Fleet surgeons. Retirement is compulsory at 55, except for Deputy Inspector-generals and the Inspector-general. But voluntary retirement is permitted after four, eight, 12, and 16 years full-pay service, with gratuities of £500, £1,000, £1,500 and £2,250 respectively. Herein lies one of the great attractions of the Service, for a man without capital entering at, say, 22 can withdraw at 30 with £1,000 to start in civil practice. Fleet surgeons retire with a pension of from £365 to £547 10s. a year, according to length of service. But if the health of a surgeon breaks down before he completes 20 years' service, he may be placed at once on the retired list, receiving no pension, but only a gratuity, even if his illness has been contracted in the performance of his duties. This seems decidedly unfair.

A naval surgeon has excellent opportunities for keeping himself in touch with medical progress, as he is obliged to attend a post-graduate course at a metropolitan hospital for five months every eight years. During this time he receives full pay and allowances for expenses.

The Doctor in the Army. The requirements from candidates are similar to those for the Naval Medical Service, except that the subjects of examination are limited to medicine and surgery. Successful candidates receive commissions as lieutenants on probation, and must undergo two months instruction in military surgery, hygiene, and bacteriology at the Staff College in London. They will be examined in these subjects and then go to Aldershot for a three months' course of instruction in technical duties, on which they are also examined. Examinations for promotion are held later. The daily pay of a lieutenant is 14s. a day, exclusive of allowances, rising with promotion and length of service to £2 a day for a colonel and £3 for a surgeon-general. Retirement is compulsory for a surgeon-general at 60, for a colonel at 57, and for other officers at 55. Failure to qualify for promotion will entail retirement at an earlier age. The rate of retired pay varies from £2 to £1 a day, according to rank. Majors of less than 20 years' service and captains receive gratuities varying from £2,500 to £1,000 in place of retired pay. If premature retirement is the result of illness produced by medical service, the officer receives retired pay equal to the half-pay of his rank. An officer volunteering for, or ordered to, the West Coast of Africa receives double pay. For each year's service here he is entitled to full pay during a year's leave at home. Each year and each half-year after the first twelve months are counted as double for purposes of retired pay.

The conditions of the Army Medical Service have been much improved of late years. The chief drawback is that there is still a tendency in certain quarters to place the medical officers on an inferior plane socially to the combatant officers.

The Indian Medical Service. Regulations for candidates in the Indian Medical Service resemble those for the Army, except that they must simply be "natural born subjects of his Majesty," European descent not being insisted on. An additional certificate is required of having attended a course of instruction in diseases of the eye for not less than three months. The subjects of the examination are now the same as for the Army. Successful candidates undergo further training at the Medical Staff College and at Aldershot as for the Army, and have a similar examination at the end. According to the result of all these examinations, they are allowed, as far as possible, to select their district in India. Leave out of India for a year, capable of extension to two years' absence from duty, is granted at certain times on pay varying from £250 to £700 a year, according to length of service. Extra leave is allowed also for purposes of study.

The system of pay is somewhat complicated, but usually starts at 450 rupees a month, increasing to 2,250 rupees for those below the rank of surgeon-general, who receives 3,000 to 2,200 rupees. Retirement takes place at 55 or 60, according to rank, and the pension ranges from £1,050 to £300 a year, depending on length of service and position. Invalid pensions are also granted to officers incapacitated by illness caused by their duties.

The competition for the Indian Medical Service is more severe than for either of the other two Services. It should be entered as early as possible, since it is almost impossible for anyone entering after his twenty-fifth birthday to reach a higher pension than £500 a year. Private practice is allowed, except to those in certain special posts, as long as it does not interfere with official duties. This allows the chance of a decidedly better income. "Specialist" appointments have recently been made, which carry higher pay with them.

It is now permitted to successful candidates in all three Services to spend not more than a year in a resident appointment at a recognised civil hospital. Time so spent counts towards promotion and pension. This is a great improvement, and encourages the best type of student to compete.

The Doctor in the Colonies. There is, of course, considerable scope for the medical man in the Colonies.

CANADA. British diplomas and degrees entitle a medical man to practise in Canada without any examination after licence obtained from the Provincial Medical Boards and registration and payment of fees. In British Columbia the registration fee "must not exceed $100," and in some parts is only $10; a small annual fee may also be charged. There are good medical schools in Canada, so that the supply of medical men is quite sufficient for the population generally, though British Columbia might offer an opening to those ready to "rough it."

AUSTRALASIA. In New South Wales, Victoria, Queensland, and Tasmania, a man who possesses British qualifications is entitled to a certificate from the Medical Board as a "legally qualified practitioner." In Western Australia a fee of ten guineas, and in New Zealand a fee of £1 5s., is charged for such registration. Registration is not compulsory in South Australia.

In Australia there is a large supply of general practitioners in the towns, and many of those who have gone out from England have found it difficult to make a living. The graduates of the Colonial universities more than meet the usual vacancies, and have more influence to help to secure them. There is, however, still some opening for specialists on diseases of the eye and ear. For others country districts offer the best chance, but the newcomer must be proficient in surgery as well as medicine, and ready to live a hard life.

SOUTH AFRICA. Here registration is necessary. For this sworn declarations must be made as to (1) personal identity, (2) authenticity of the diplomas, and (3) the fact that these diplomas entitle the applicant to practise in the country where they were obtained. Registration by the General Medical Council of Great Britain will be found to simplify these procedures.

In Cape Colony the licence is signed by the Colonial Secretary on the recommendation of the Colonial Medical Council. The fee is £5. In Natal the application for such a licence costs £1 1s., and the annual fee is £5. In Southern Rhodesia the licence is issued by the Chief Secretary, Salisbury. The fee is £5. In the Transvaal the certificate is issued on the recommendation of the Transvaal Medical Council on payment of £10. In the Orange River Colony the Registrar of the Medical and Pharmacy Council, Bloemfontein, issues the certificate. The stamp is £7 10s., and the annual licence costs £15.

In Cape Colony there are numerous appointments as district surgeons and medical officers. Candidates should apply to the Assistant Private Secretary, Colonial Office. Applications for appointments in Rhodesia should be made to the Secretary of the British South Africa Company, London Wall Buildings, E.C., together with certified copies of diplomas and testimonials. Preference is given to applicants who have passed through a course of training at the Tropical School of Medicine. It is desirable that they should be young, of good physique, and able to ride.

Those who go out to South Africa with a view to private practice must remember that though fees are high, so is the cost of living, and that methods of competition are in vogue which are not sanctioned in Great Britain.

Other Colonies. Medical appointments fall vacant from time to time, mainly in the West Indies and the West African Colonies. Candidates must be between the ages of 23 and 30, must be doubly qualified—*i.e.*, in surgery and medicine—and must apply to the Assistant Private Secretary, Colonial Office.

The Doctor on the Continent. On the Continent, as a rule, fewer opportunities offer themselves to the practitioner.

Italy. Italy is the only country that places no restriction on the foreign practitioner. He has no fees to pay, examination to pass, or forms to comply with. The authorities recognise the benefit of the large influx of visitors and the necessity of considering their comfort, so that a recent agitation to expel all foreign practitioners has met with little support. The shortness of the season in most districts means, however, three or four months of incessant labour, followed by comparative idleness during the rest of the year, unless it is combined with a practice in some summer resort, entailing the expense of a double establishment. As such practices are of a purely personal and non-transferable nature, they should not be bought. Good general attainments, and especially good introductions, are of more value than a bought connection.

France. Application must be made to the Minister of Public Instruction, accompanied by sworn translation of the birth certificate and diplomas viséd by the British Consul. Then the degree of M.D. in a French University (involving five examinations) and the "diplome de Bachelier," must be obtained before practice is allowed. Classes must be attended even by the qualified foreigner, though he does not have to wait the statutory intervals between his examinations. When all these difficulties have been surmounted, a man who can accommodate himself to his surroundings may find a good opening in towns where there is an English-speaking element.

Germany. All the classes must be attended, and all examinations have to be passed. As this involves a five years' course and about £160 to £170 in fees, it is practically prohibitive. Practice is allowed to holders of British diplomas, but they must not make use of titles resembling those of German medical men, and legally they are regarded as unqualified. Under such circumstances Germany offers no attraction to the British medical man.

Austria. Naturalisation, involving five years' residence, is necessary, and all the examinations must be passed.

Hungary. Application must be made to the Minister of Education, three examinations must be passed, and a fee of 80 crowns paid.

Switzerland. Three examinations must be passed (fee £9), and one or two years spent in additional study.

Spain (and Canary Islands). The diploma must be sent to the University of Madrid, and identity proved. Practice is then allowed on the payment of certain duties.

Portugal (including Madeira and Cape de Verde Islands, where there is a considerable British element). Examination and a printed dissertation are required. Cost of examination and diploma, £50.

Turkey. A "colloquium," or easy oral examination in French or Turkish, without interpreter, is held. No European physician has ever failed to pass this, but there may be many delays before the examination is actually held. Fees, £8, in addition to some registration expenses.

Egypt. Qualified British practitioners have only to show their diplomas to the Director General of the Sanitary Department in Cairo, obtain a certificate of good character, and pay a small registration fee. Formerly Egypt offered a splendid opening, but so many availed themselves of it that this holds good no longer. No one should go there unless he has obtained an appointment in the Kasr-El-Ainy Hospital or in the Sanitary Department, for which the competition is considerable. A knowledge of Arabic is essential.

Japan. There is no difficulty in an English medical man obtaining a licence, which only costs about six shillings, but the only opening is for shipping work and as medical officer to business houses.

United States of America. The methods of admission vary in the different States, and are not exacting, but the proportion of medical men to the population is higher here than in any other country, so that competition is very severe in all the situations that are in any way desirable.

THE SPECIALIST

In view of the enormous growth of specialism in medicine, an increasing number of the more ambitious students will desire to equip themselves for such work. It cannot be too clearly understood that whatever speciality a student may be aiming at, it will be necessary for him to become fully qualified to practise both medicine and surgery first. In addition, if a surgical speciality is his goal, the F.R.C.S. is essential to him; if medical, he should become an M.D. of the university in which he was trained, and take the M.R.C.P. The F.R.C.P. is only obtained by election from the more distinguished M.R.C.P.'s, the choice being practically vested in the Council of the College of Physicians.

The Position of the Specialist. It must be remembered that specialism is more popular outside than within the profession. The profession recognises a clear distinction between general practitioners and consultants, the latter treating only patients in conjunction with the general practitioner. The consultant may practise surgery or medicine, never both. The rapid growth of knowledge has made it impossible for the consultant to keep in touch with the whole of either subjects, however. Certain departments, such as diseases of the eye and the diseases of women, have long been relegated to specialists. Diseases of the throat and ear, and of the skin, are now almost entirely treated by specialists. Subjects such as electrical treatment and public health have recently been marked off as separate departments; but beyond this the profession rightly discourages excessive specialism as encouraging too narrow a view. A man elects to practise medicine or surgery, but his gradual recognition as a specialist in some department of either subject depends largely on his fellows who may seek his help on some point to which he has paid special attention.

To specialise in public health a diploma, D.P.H., should be obtained in the subject. This necessitates at least a six months' course in the subject at the hospital, after qualification (fee, usually £21), and examination by the universities or the Colleges of Physicians and Surgeons (fee, usually £21). The successful candidate then attempts to be elected Medical Officer of Health for some borough or district council.

The Specialist's Prospects. This is the only speciality requiring a separate examination. As to the others, it is inadvisable for a student to choose too soon in his career. He must see how his abilities, tastes, and opportunities develop. After qualification, he must aim at holding a resident appointment at a hospital devoted to the speciality he desires to follow. A three or six months' course at a continental clinic, such as Vienna, would then be very valuable. On returning he must try and become a clinical assistant at a hospital in his special subject. A teaching appointment at his own hospital is one of the most powerful levers he can obtain towards his upward progress. He must aim at getting a permanent appointment on the visiting staff of a hospital as soon as possible. The degree of success he has had in his teaching work and as clinical assistant will prove important factors in accomplishing this aim.

It will be seen from this that to become a recognised specialist is a tedious procedure, involving years of unremunerative work. Even when success begins to come, the income earned is much smaller than the public imagines. So much time must still be spent in hospital work and research in order to keep abreast of the times. A specialist must remain a student all his life, always ready to learn and apply the latest scientific work. Without capital it is almost impossible to live through the early years of waiting, though quite exceptional men have done so. A young surgeon has a much better chance than a young physician, because he can earn fees by helping a senior at his operations, and by doing operations at reduced fees, the graduation of fees being much more marked in the case of surgeons than physicians. But a physician goes on earning his income later in life.

In any case the harvest-time for so much preparation is but short, competent authorities putting it at only fifteen years.

It will be seen that the pursuit of specialism is arduous and hazardous. There are as many blanks as prizes to be drawn, and no one should take it up as a career without carefully counting the cost.

HOMŒOPATHY

By Dr. John H. Clarke

Homœopathy is a science and art of healing founded on a law of Nature known to exist from time immemorial, but first clearly enunciated and systematised by Dr. Samuel Hahnemann about the close of the eighteenth century.

Hahnemann was the leading authority on pharmaceutics of his day, being the author of the classic "Apothekerlexicon." He was, therefore, fully acquainted with all that related to the practical side of drugs and their preparations. He was a great scholar and linguist, and was the translator of works from many languages into German. It was whilst translating the work on Materia Medica by Professor Cullen, of Edinburgh, that the idea occurred to him of testing the action of cinchona bark on his own healthy body.

The result of this experiment was that it produced in him an exact picture of an attack of ague—that is to say, it produced a condition presenting symptoms *like* those of a state of disease it was known to cure. This led Hahnemann to test other drugs in the same way, and he found the law held good. Whenever a case of illness presents symptoms closely resembling those produced by a drug on healthy persons, this drug will be the remedy for the case. In the work of experimenting with drugs, Hahnemann obtained the help of a number of friends as well as of members of his own family. The results of these labours was the building up of one of Hahnemann's great works, the "Materia Medica Pura"—that is to say, the actual observed effects of drugs unadulterated with any admixture of theory or opinion.

In this work the symptoms actually produced by each drug on the experimenters are arranged in a definite schematic order for handy reference. Another discovery of Hahnemann's was the increased sensitiveness of patients to the action of a drug which is homœopathic to the case. This necessitated his giving a much smaller quantity of a drug for the cure of a patient than was required for the production of the like condition in a healthy person. This led to Hahnemann's invention of a graduated method of attenuating medicinal substances up to a high infinitesimal dilution. The recent discoveries in regard to radium and light treatment have familiarised the scientific world outside homœopathy with the power of infinitesimals. A full statement of the homœopathic doctrine is contained in Hahnemann's great work "The Organism of Medicine." His third great work is entitled "On the Nature of the Chronic Diseases."

Qualifying for the Profession. In this country at the present time anyone desiring to enter for the homœopathic profession must first obtain a qualification in one of the recognised colleges or universities. After graduation, the British Homœopathic Association, 233A Regent Street, W. (President, Earl Cawdor), arranges for him an academic systematic course of lectures on Homœopathic Materia Medica and Homœopathic Therapeutics during the winter session, and during the summer session of each year a further course of Homœopathic Therapeutics is given. Ample opportunities for clinical instruction and clinical work are always afforded at the London Homœopathic Hospital, Great Ormond Street, W.C., and at the homœopathic hospitals of Liverpool and Birmingham. In addition to this, much valuable instruction may be gained by watching the practice at such homœopathic hospitals as those at Bromley, Tunbridge Wells, Bournemouth, and elsewhere.

In addition, the British Homœopathic Association is sending young medical men to America every year to be instructed in the homœopathic colleges there. A further excellent means of becoming thoroughly acquainted with the details of homœopathic practice is by obtaining a resident medical post at one of the above-named hospitals.

The prospects of any capable man who possesses a good knowledge of homœopathic practice are much better than those of one who lacks it. The demand for homœopathic practitioners is very much greater than the supply. In cases where a start is made in a new district, the British Homœopathic Association gives its support to a fitting candidate until such time as he has been able to make his position secure. It never takes long to do this, so great is the demand among the laity for homœopathic treatment. This demand comes from all grades of society, from Court circles downwards.

THE VETERINARY SURGEON

By Dr. Gerald Leighton

There is only one portal to the ranks of veterinary surgeons—namely, the prescribed examinations of the Royal College of Veterinary Surgeons. No matter where the student enters and studies, the examinations are identical, and are controlled by this body alone. In this the veterinary profession differs from medicine, in the latter profession the student having a choice of degrees or qualifications, any one of which allows him to practise as a physician or surgeon. In veterinary science, however, every practitioner must pass the M.R.C.V.S. (Member of the Royal College of Veterinary Surgeons), that being the only legal veterinary qualification in Great Britain.

The Veterinary Surgeon's Course of Study. The first stage is to pass the preliminary examination in general knowledge, just as it is in medicine. This has been recently altered and the announcement made that "Candidates not yet attending a veterinary college must take the Examination on the Medical Preliminary Standard at the January and April Examinations (1907), and also at all future dates." As we are writing for those who are prospective veterinary students, not for those already in the profession, it will be sufficient to draw attention to this important announcement as it stands, referring our readers to what has been already said concerning the medical preliminary examination. The list of examining bodies whose certificates of examinations in general education are accepted in lieu of the preliminary are similar to those for the medical preliminary. Full particulars of these may be obtained from the secretary of the Royal College of Veterinary Surgeons. A certificate of having passed all the required subjects in this examination before entering college entitles the student to present himself for his first professional examination.

The preliminary examination passed, the student has then to determine in which college he will take his course. He has the choice of colleges in London, Edinburgh, Dublin, Glasgow, and Liverpool. Before very long, in all probability, other universities will institute a faculty of veterinary science, as has been done in Liverpool. The choice of the college will doubtless be determined to a certain extent by the student's place of residence, the actual cost of the various classes in the various colleges not varying more than a few pounds per annum. Of course, if the student has to leave home and live in rooms, he must decide which place suits him best from the financial and other standpoints of living. Class fees amount to £20 a year, or slightly less, to which must be added books, cost of living, and examination fees. The whole course of study, extending over the minimum period of four years, together with the subjects for the four professional examinations and the fees payable, is shown in the following table. There are only two examinations held during the year—*viz.*, in England and Ireland in July and December, and in Scotland in May and December.

Final Examination and Prospects. Any veterinary surgeon who has been in practice for a period of five years or upwards who produces a certificate of fitness may proceed to the examination for the Fellowship of the Royal College of Veterinary Surgeons. This is a higher examination, just as the M.D. is in the sister profession. For this the candidate must write an original thesis, and defend this thesis for half an hour before the examiners. He must also undergo a written examination in veterinary medicine, surgery, hygiene, sanitary science, pathology, and bacteriology. This examination is held in May and December in each year. A fee of £5 5s. is payable on sending in the thesis, and on passing the examination and receiving the diploma a further fee of £10 10s. Having successfully passed his M.R.C.V.S. final examination, the veterinary surgeon has then to decide the important point

SCHEDULE OF EXAMINATIONS FOR VETERINARY SURGEONS

Examining Body. Diplomas. Time and places of Examination.	SUBJECTS OF EXAMINATION		Fees and Age Limits
	Compulsory.	Optional.	
ROYAL COLLEGE OF VETERINARY SURGEONS. M.R.C.V.S. and F.R.C.V.S. Entrance. Edinburgh, Glasgow, London, Liverpool, Dublin.	English, including Composition, Dictation, Parsing, and Derivation. Latin, Grammar, Translation into English. Mathematics, Arithmetic, Algebra up to Simple Equations (inclusive). Geometry, Euclid, Books I. to III., with Deductions.	One of the following: Greek, French, German, Italian, any other modern language, Logic. Candidates not yet attending a Veterinary College must take the Examination on the Medical Preliminary Standard at the January and April (1907) Examinations, and also at all future dates.	£1 None
For M.R.C.V.S. First Professional. May and December. Edinburgh, Glasgow. July and December. London, Liverpool, Dublin.	Elementary Anatomy, Chemistry, Biology (Botany and Zoology).		£5 None
Second Professional. Time and place as above.	Anatomy, Physiology (Histology), Stable Management (Manipulation and Shoeing).		£5 None
Third Professional. Time and place as above.	Pathology and Bacteriology, Materia Medica (Toxicology), Hygiene (Dietetics).		£5 None
Final. M.R.C.V.S. Time and place as above.	Veterinary Medicine, Surgery, Obstetrics, and Meat Inspection.		£5 Registration Fee £1 21 years.
For F.R.C.V.S. May and December. London. Or by arrangement elsewhere.	Thesis. Written Examination on Medicine, Surgery, Hygiene and Sanitary Science, Pathology and Bacteriology.		Entrance £5 5s. Passing £10 5 years in practice

of which branch of his profession is to engage his attention. There is a wide choice. He may decide upon general practice in town or country, and in that sphere a good practitioner will make a good living, if not a large fortune. Corporation appointments as meat inspectors attract some. He may specialise, devoting his attention chiefly to dogs, or horses, or cattle, etc., and will find his services in high demand where valuable pedigree animals are concerned. A good veterinary surgeon in any well-known hunting district in England has every opportunity of making a good position. The hardest life is undoubtedly that of the country practitioner in a sparsely populated district where his clients are not too well off and his patients not sufficiently valuable to justify much expenditure upon them.

The Army Veterinary Department.

Of recent years, especially since the Boer War, great changes have been made in the Army Veterinary Department, which now offers a good career to a certain number. The rates of pay and rules regarding the promotion and retirement of veterinary officers are laid down in the Royal Warrant for Pay, a copy of which should be obtained by intending candidates for the Army. The requirements demanded of candidates are these:

(1) Candidates for admission must make written application to the Secretary, War Office, London, giving the information required by Appendix I. A personal interview with the Director-General, Army Veterinary Service, will subsequently be necessary, and will be arranged by that officer.

(2) The minimum age of candidates is 21 years, and the maximum age 27 years, except in very special cases or on urgent occasions, when the latter limit may be exceeded. Candidates must be unmarried, and will not be accepted unless, in the opinion of the Army Council, they are in all respects suitable to hold commissions in the Army.

(3) Every candidate must be a member of the Royal College of Veterinary Surgeons, and pass an examination before a board of veterinary officers.

(4) He will be required to forward the following certificates, prior to examination: (*a*) a certificate of birth or other satisfactory proof of age; (*b*) certificates of moral character from clergymen or others in a position to testify, and whose evidence may be deemed satisfactory.

(5) The Dean or other responsible head of the school from which the candidate graduated will be asked by the Director-General for a confidential report as to his professional ability and general fitness to hold a commission in the department.

(6) If approved, he will be examined as to his

then be eligible for examination.

(7) Examinations will be held on vacancies occurring, and candidates who obtain the qualifying number of marks will receive commissions according to the order of merit in which they pass.

(8) Candidates will be examined by the Examining Board, and the examination will be in two parts, written and oral, as follow:

WRITTEN

	Maximum marks.
Veterinary medicine (2 hours) ..	1,000
„ surgery „ ..	1,000
„ hygiene „ ..	1,000

(General papers referring to both horses and cattle, and embracing pathology in all its branches, surgical anatomy, and general and special hygiene.)

To qualify—50 per cent. in each subject.

ORAL

	Maximum marks.
Examination of horses, including soundness generally and certificates thereon, ageing, shoeing, the eye, and detection of lameness	3,000
Clinical diagnosis, the practical handling of animals and administration of medicines	2,000
Practical surgery and surgical anatomy	2,000

To qualify—50 per cent. in each subject.

An aggregate of 60 per cent. in all subjects combined will be required.

A candidate may be rejected if he shows any deficiency in his general education.

A candidate on appointment as veterinary officer will, on joining at Aldershot, be required to undergo a course of special training at the Army Veterinary School.

At the end of the course he will be examined, and if the examination be satisfactory and his general report good he will be retained in the Service; but should his examination be unsatisfactory, or his general report not good, his services will be dispensed with, in accordance with the last part of Article 431 of the Pay Warrant.

Rates of Pay in the Army. The substantive ranks of the officers of the Army Veterinary Department are as follow: colonel, lieutenant-colonel, major, captain, lieutenant. After passing the examinations the candidate is appointed a veterinary officer on probation for six months, after which, if satisfactory, he receives a commission as lieutenant at £250 per annum. The ordinary rates of pay are as follows (those of special pay abroad, with the army in the field, or in command at home, sick leave, retired pay, etc., will be found in the Pay Warrant):

Director-General, £1,200 a year	Inclusive of all allowances except field and travelling allowances.

	Daily.		
	£	s.	d.
Colonel	1	15	0
Lieutenant-colonel	1	10	
Major	1	0	
„ after 5 years' service as such ..	1	2	
„ „ 10 „	1	4	
Captain	0	15	
„ after 5 years' service as such, provided he has served 3 years abroad	0	17	6
Lieutenant	£250	0	0 a year

veterinary work, in which the officers perform or supervise all official veterinary work in India, other than that of the Army, and are debarred from private professional practice in India. The duties are mainly educational work in veterinary colleges, horse and mule breeding, cattle breeding, and the treatment of disease. Applications for these appointments should be made to the Revenue Secretary, India Office, London, S.W.

Thus, the veterinary surgeon has an abundant choice of modes and places in which he may practise, and before coming to a decision he will do well to consult those who have experience of the branch he intends to pursue.

THE BEST FOODS FOR POULTRY

Feeding for the Table or for Egg-laying. Some Typical Rations for Young Chickens and Adult Hens. A List of Suitable Foods

continued from page 5264

By Professor JAMES LONG

IN connection with the feeding of poultry the reader is referred to pages 2702-6, in which the principles of the feeding of livestock are discussed. Although this discussion refers in particular to the larger animals of the farm, the major portion of those pages may be applied with equal advantage to poultry. Not only have we provided a table of analyses showing the percentages of the various digestible constituents of foods, but those constituents are described in detail and their relative values compared.

The Hen's Carcase. In feeding poultry we are bound to observe the difference in size between the hen, and, let us say, the sheep or the bullock, the greater rapidity with which food is utilised, especially in the formation of the two materials of which the body of the hen is chiefly composed—fat and protein, which comprise nearly one half of the dry matter of the carcase; and the fact that she is an omnivorous feeder, eating animal and vegetable food with equal felicity. In passing, it may be observed, too, that the composition of the dry matter of the hen's carcase—we do not refer to fowls which have been fattened—is closely identical with that of the dry matter of the egg. As an omnivorous feeder, then, it is clear that the food supplied to poultry should be varied. In practice, however, we find that where one individual chiefly feeds his poultry upon maize, another selects barley, while a third may employ maize as hard food and barley-meal in the form of paste, which so many persons regard as an important feature in feeding, especially when it is supplied hot in the morning, having been mixed with skim milk, or the liquor in which meat or bones have been cooked.

Feeding Chickens for the Table. Food is supplied to poultry, in the first place, for the maintenance of their bodies, and next for the production of meat or eggs. Chickens which, after hatching, are intended for the table, should, like the calf intended for veal, be well fed from the egg forwards, every effort being made to induce growth accompanied by an increase of flesh. Where chickens are intended for laying purposes—and here we naturally refer to the pullets—the same form of treatment is not an essential; and yet the feeding should be equally careful, for the stronger and healthier the chicken the more robust and vigorous becomes the young fowl, and indeed the earlier she begins to lay. Success lies, however, rather in the direction of variation in the rations as between chickens intended for table and the pullets for laying than in the quantity of food supplied. The demand for fattened chickens, valuable as it is from a pecuniary point of view, is not a healthy one; but in his own interest the poultry-keeper must respond to it. The object is to send into the market at the earliest date young birds, tender and fat, for which he receives what we now regard as unparalleled prices, especially in the early season. We have noticed such birds priced at 10s. 6d. each in the West End of London, but they were the result of considerable labour and skill on the part of the producer.

Feeding Pullets for Egg-laying. The pullet intended for laying should be fed naturally, and supplied with all she requires, and the greater her freedom and the larger the quantity of insect life, grass, and clover she can obtain the better for her growth and strength. But the chicken for the table is, at a given age, which is more or less closely prescribed, caged and crammed with food, a large proportion of which consists of fat, and, having added to her weight sufficient for the purpose of the feeder, is killed and sent to market.

Food is rapidly appropriated by poultry, especially by young chickens, and there is little doubt that appropriation or assimilation are still more rapid and effective when the ration is mixed.

The Feeding Value of Milk and Bone. Although cereals are principally employed as food, pulse and other grains are occasionally supplied, together with milk and meat in some variety. The value of milk is noticeable in two directions. It is believed that the protein of animal food, as in the casein of milk, is better assimilated and employed in the economy of the fowl than the protein of cereals or pulse, and, further, that the necessity for mineral matter—especially for phosphates—is more readily met by meat and milk than by vegetable food of any kind. Where, therefore, cereals are employed—we especially refer to wheat, oats, barley, maize, and rice—the ration should be supplemented, especially in the case of chickens intended for laying, and thus raising to adult age, by bone supplied in one of its various forms. Here we would point out that bone should be fresh and unboiled. Bone contains two materials which are of great value to poultry—phosphate of lime, as essential in the construction of bone as lime in the construction of the shell of the egg; and the albuminoid matter which we will describe under the general term of protein, which is extracted by boiling, and which is the valuable constituent produced in the kitchen as the foundation of stock for soup. Boiled bones, therefore, should be avoided, and for a similar reason many brands of bone-meal or ground bone. The wisest plan is to obtain a crushing machine, which is now especially made for poultry-keepers, and to break up into fine pieces bone fresh from the butcher. If bones are used with liberality, birds which are confined to pens or runs will need no special provision of materials containing lime for the manufacture of the shell, which weighs about 10 per cent. of the whole egg.

The Laying Hen Needs Lime. It has been shown by careful demonstration that under ordinary feeding conditions, the birds being kept in confinement, only about one-tenth of the lime in the eggshell was accounted for as having been obtained from the food, the remaining nine-tenths being extracted from materials chiefly composed of lime. It need hardly be suggested that the laying hen requires lime in much greater abundance than the chicken or the non-laying hen, and the remark equally applies to phosphates. It is found in practice, however, that all classes of poultry thrive better upon food which is rich in phosphates; hence, again, the importance of milk, bones, of meat, and of every class of food which is rich in these materials. Laying hens require about one ounce of fresh cut bone or meat daily, allowance being made for their size.

And here, again, it is essential to refer to the supreme importance of careful observation on the part of the feeder. In daily practice flocks of poultry are fed alike, almost without discretion, whereas both common-sense and experience suggest that not only size, but age and individuality demand special attention. Hens which have ceased to lay owing to age, weather, or moulting should not be fed upon the same ration as young birds which are laying. Large hens require more food than small hens, but for maintenance they require less per pound of live weight. In practice we have found that hens of average size require a quarter of a pound of heavy grain, such as maize, wheat, or barley, or its equivalent daily. This, equal to some 4 oz., experimenters have found to be almost precisely what laying hens require for the provision of heat, repair of waste tissues, the exercise of energy, and the provision of the egg. If we suppose that an egg laid by a good-sized hen contains 2 oz. of feeding matter, about three parts of which is water, it follows that the food consumed must provide for the elaboration of half an ounce of dry matter, which chiefly consists of yolk—largely oil—and albumin.

Heightening the Colour of an Egg's Yolk. There is every reason to believe that food is not accountable for the delicious flavour of the yolk of the eggs laid by certain hens, which resembles that of the guinea fowl, but that it may be perpetuated by selection in breeding, and by this process only. On the other hand, there is equal reason to suppose that the colour of the yolk is influenced by the food consumed—thus, where hens are deprived of green food, and especially of grass and clover, the yolk is often pale, whereas the yolk of hens at liberty in green fields is usually high in colour. Essential as green food is to hens, it is important to remember that they should not be allowed to consume too large quantities in place of grain or meat. The system of the hen demands food of a concentrated character, hence the importance of relying chiefly upon those foods which are usually supplied. The food consumed having been softened in the crop, is practically masticated, or very finely ground, in the gizzard, and, by the aid of the digestible juices, quickly assimilated, and, after providing for maintenance, converted into meat or egg.

The Albuminoid Ration for Poultry. The student of poultry feeding will do well to refer to the remarks on the albuminoid ration, page 2706, in which the principle of supplying the constituents of food in accordance with the requirements of the animal are explained. We need, therefore, merely point out that the nutritious matter of food is divided, minerals apart, into three groups—the fats or oils, the carbohydrates, chiefly starches and sugars, and the albuminoids (protein), which alone contain nitrogen, and which are therefore alone responsible for the production of the albumin of the egg, and the muscle, and other lean or nitrogenous parts of the carcase. In practice it is found that a ration composed of one part of albuminoids and five parts of carbohydrates and fats is followed by the best results. The method of calculation will easily be understood if the chapter we have referred to is carefully read, and if reference is made in the preparation of a ration to the analytical table which accompanies it. The foods which are rich in albuminoids, and which are chiefly used in feeding poultry, are meat, bone, peas, beans, lentils, malt combs, bran, linseed, cotton-seed meal or cake, clover, lucerne, vetches and sainfoin, the two latter being either green or dried.

Fats and Carbohydrates. The foods rich in oil or fat include linseed, linseed cake, decorticated cotton cake, the fat of meat, and, on a smaller scale, maize and other cereals, the best ricemeal, and maize germ meal. Foods rich in starch and sugar are common enough, and their employment may be almost essentially regulated by the market-price. They include wheat, barley, oats, maize, rice, dari, buckwheat, groats, oatmeal, ground oats, fine sharps or middlings, sometimes described as toppings or fine dan.

Oatmeal and groats, together with the ground oats of Sussex, in which the husk is finely ground with the kernel, are valuable for chickens, especially when supplemented by fine-cut bone and mixed with new or skimmed milk; and here we may add that new milk is not only rich in fat, but especially rich in albuminoid matter, and highly adapted, either as a drink, or supplied in the form of curd to the feeding of chickens of all ages. Similarly, skimmed milk, although deprived of its fat, is rich in albuminoid matter, and is of great value when employed for mixing the various meals into paste, especially the cereal meals which are so deficient in albuminoids. The same remark applies to potatoes, which, rich in starch, although a bulky food, owing to their large percentage of water, are rendered much more valuable for feeding adult fowls when similarly mixed with skimmed milk and pulse meal.

Some Typical Rations and their Cost. No Englishman has accomplished better work in the poultry industry than Sir Walter Palmer, of Reading, who some few years ago established a poultry farm near Winkfield, in Berks, on soil which, chiefly pasture, consists of fairly stiff clay. Reference is warrantably made to the system of feeding, owing to the success which has attended the work, and which was shown for the first three years in published balance-sheets. A ration consisting of 1 lb. each of pea-meal, cracked maize, potatoes, and meat, 3 lb. of biscuit meal, and 2 lb. of swedes, the whole costing fivepence, sufficed as an autumn morning food for seventy hens, each bird thus receiving 2 oz. of food. The potatoes and swedes were steamed, the meat—horseflesh, costing a halfpenny per lb.—being added later, and subsequently the maize. The second meal consisted of 10 lb. of wheat, costing 8d.—this grain being steeped during hot weather—or heavy oats, these foods being distributed on the grass, or scattered among straw during hard frost, to induce the birds to exert, and thus warm, themselves in finding it. During autumn and winter the two rations practically cost 1¼d. per bird per week, or 1½d. where grit and lime rubbish, both being purchased, were added. The cost during the summer months was slightly less. During summer, when insect life is abundant, and when grass, clover, and other herbage are young and sweet, hens at liberty, like chickens, find a large proportion of their food.

Food for Very Young Chickens. In the arrangement of the feeding of chickens, no food is supplied during the first twenty-four hours by Sir W. Palmer's manager. The first food provided consists of breadcrumbs, fine oatmeal, and boiled eggs, followed next day by coarse oatmeal, boiled rice mixed with toppings, buckwheat, and broken wheat. Such is the ration supplied during the first fortnight, after which meat is added, and fine bone-meal mixed with the soft food. It was found by observations made in February, when feeding the chickens in a rearing house, where the only food consumed was that supplied by hand, that 28 youngsters, 8½ weeks old, consumed in one day 11 oz. of bruised oats, 14 oz. of rice, bone-meal, oatmeal and milk, 10 oz. of broken wheat, and 12 oz. of buckwheat. In another case, 32 chickens, 6½ weeks old, consumed 34½ oz. of the same foods, chiefly bruised oats, while 23 chickens, 2½ weeks old, consumed in the day 7½ oz. of bruised oats and 2 oz. or rice, bone-meal, oatmeal, and milk.

In feeding chickens intended for the table, between March and June, the system already referred to is followed by a course of three weeks' feeding in pens. At first the birds receive ground oats, toppings and skimmed milk. This preliminary feeding is followed by cramming with the same foods, to which ¼ oz. to ½ oz. of fat per bird is added per day. Sixty-four birds fed by the aid of the cramming machine on a particular day in July, when fat was not being supplied, consumed in the morning 20 lb. of milk, 12 lb. of ground oats, and 3 lb. of toppings; and in the evening, 18 lb. of milk, 10 lb. of ground oats, and 3 lb. of toppings, or 28 lb. of solid and 38 lb. of liquid food, practically 1 lb. per bird per day, scarcely one half of which was solid food. The value of this food, estimating milk to cost 4d. per gallon, the oats 1d., and the toppings ¾d. per lb., was thus 3s. 6½d., or less than ¾d. per bird per day, or 10½d. per bird during the 14 days of cramming.

An Example from the United States. It will be equally instructive to take an example from the United States, where poultry feeding is now conducted on an extensive and especially practical scale. Professor Jordan, remarking on this case, points out that a day's ration for 800 to 1,000 chickens in their second week, consisted of 4 lb. of cracked wheat, 2 lb. of oatmeal, 3 lb. of maize meal, ½ lb. each of buckwheat and wheat middlings, ground oats, and linseed meal, 2¼ lb. of animal meal, and 2¾ lb. of lucerne. For ducklings of three weeks old a ration consisting of 8 lb. of maize meal, 3 lb. of middlings, 2 lb. each of barley, linseed meal and fresh bone, 6 lb. of animal meal, and 3 lb. of green lucerne, might be similarly supplied, the birds being at liberty, and finding grit and lime rubbish for themselves.

We will now give a list of the foods which are especially suited to poultry.

Wheat. Wheat is a grain suitable for chickens on account of its size and its nourishing character, but, being deficient in oil and albuminoids, it should be given only occasionally. Tail wheat—that is, the small and broken grains removed from the bulk in the process of dressing for market—is most suitable, bearing the price in mind; but farmers, as a rule, prefer to keep this for the use of their own poultry.

Barley. Barley is also especially valuable, although, like wheat, it is deficient in both albuminoids and fat; but plump samples, especially as regards the price, are less valuable than smaller grain, which contains proportionately less starch. Tail barley, obtainable from farmers, is therefore suitable, but foreign barley, which is largely composed of husk, it is not advisable to buy, although this forms a very large portion of the composition of barley meal. When barley meal is used, it is preferable to buy the barley and have it specially ground. We know from actual demonstration that the barley meal of commerce is sometimes composed of the grindings of other grain, weed seeds, and refuse extracted from corn of various kinds in the process of dressing in the mill.

Oats. Oats are richer in fat than either barley or wheat, but are also deficient in albuminoids. The oat is, however, better balanced, especially where the sample is not too heavy, and consequently rich in starch. This grain is better supplied in the form of oatmeal or groats for very young chickens; or of ground oats, especially as prepared by Sussex millers, for chickens of larger size and for adult fowls. Oatmeal is slightly richer in starch and poorer in fats and albuminoids than the oat grain. It is, however, an especially good food.

Maize. Maize is now supplied in various forms through its by-products; the grain is richer in oils than either of the cereals already mentioned; it is extremely rich in starch, but comparatively poor in albuminoids, and is not adapted for young chickens, except when cracked and given occasionally, or as a regular food for adult fowls, and the remark equally applies to maize meal. The germ of maize, however, although less palatable, is richer in albuminoids or muscle-forming matter, and extremely rich in oil, and may be used as an addition to those mixtures of meals which are poor in oil. The actual germ of maize contains 21½ per cent. of protein or albuminoid matter, 34 per cent. of starchy matter, and 29 per cent. of fat. The germ consists of about 10 parts of the original grain, the skin about 5½ parts, and the starchy matter and harder parts 84½ per cent. A material known as gluten meal, produced from maize, while containing about 50 per cent. of starchy matter, also contains 33 per cent. of protein: while an American food, known as gluten feed, contains slightly less protein and a similar quantity of starchy matter, but considerably more fat. These foods, although rich, and useful in consequence, are not altogether palatable to stock, but they may be employed in mixtures which are spiced, and so rendered agreeable to the birds.

Rice. Rice is a food which is so poor in fat and albuminoids, and so rich in starch, that it should be given in conjunction with a food like skimmed milk, in which it is best boiled or soaked. Rice meal, however, unlike the naked grain, is rich in oil, while it contains 50 per cent. more albuminoids than the whole grain and a smaller proportion of starch; for this reason, if pure, it may be employed with advantage, but care is needed in its selection.

Buckwheat. Buckwheat is a grain much relished by chickens, although it is not equal to the best cereals, being especially poor in oil and albuminoids, but it affords a useful change.

Dari. Dari, which is often given as a change food for small chickens, is rich in starchy matter, but relatively poor in other feeding constituents.

Ground Food. Of the various forms of ground food or meal, we may especially refer to fine *middlings*, sometimes known as *toppings* or *dan.* The true sample should be floury, and mix into a good paste, for there are various brands of sharps and shorts which are chiefly composed of the husk of the wheat grain. This food, mixed with skimmed milk, is excellent, and may be frequently used with advantage. *Bran* is sometimes used as a food for poultry, but it is not economical when it costs more than £5 a ton. A good sample is well balanced, except for the small quantity of fat it contains. *Pea meal*, which is rich in albuminoids, like *lentil meal* and *bean meal*, is useful for mixing with foods which are rich in starch, but these foods should be used in comparatively small quantities. Decorticated *cotton-seed meal* may be similarly employed when it becomes necessary to raise the fat and albuminoid percentage of a ration. Crushed *linseed cake* may be employed in the same way; it is an exceptionally rich food, though much more costly than the majority of poultry foods.

Green and Dried Fodders. Green and dried fodders, such as *lucerne* and *clover heads*, are always useful. They may be given to birds which are in confinement fresh in summer and dried in winter, having been plucked from the stalks for the purpose, for it should be remembered that as poultry require food in a concentrated form, the dried stalks are better removed, these being much less nourishing.

Roots. The *potato* is sometimes given to adult fowls, but owing to its large percentage of water (nearly 77 per cent.), and the fact that the residue is chiefly starch, it should be mixed after cooking with a small quantity of skimmed milk and a meal rich in albuminoids, such as that derived from peas, beans, lentils, cotton-seed, or linseed.

Roots such as *mangels* and *turnips* have little feeding value, but they are much relished by poultry, and a *bulb* cut in halves and placed in the run where birds are confined will assist in maintaining a healthy condition, and practically take the place of ordinary green food, such as cabbage or lettuce.

Meat and Fish Foods. With regard to meat and fish foods, a variety of which are on the market, it may be mentioned that animal meal sometimes employed by poultry keepers is extremely rich in mineral matter, of which it contains over 30 per cent., with 35 per cent. of protein, and 12 per cent. to 13 per cent. of fat. A useful form of meat meal contains a very small percentage of mineral matter, but 70 per cent. of protein, and a similar proportion of fat, while dried blood contains 34 per cent. of protein and 2½ per cent. of fat; this, however, is not rich enough in minerals. On the other hand, a dried fish food contains 30 per cent. of mineral matter and 48 per cent. of protein, with a small quantity of fat.

Milk and its Products. Foods prepared from milk are of the greatest value to the poultry keeper, whether for the feeding and rearing of chickens or of adult fowls. Rich milk contains some 3½ per cent. to 5 per cent. of fat, over 3½ per cent. of casein, and albumin, both of which are proteids, and from 4½ per cent. to 5 per cent. of sugar. When deprived of its fat, the proportion of sugar and proteids is slightly increased, while the cost price is immensely reduced.

Whey, the residue of the cheese-room, only contains a small quantity of protein, but about 5 per cent. of sugar. New, or full milk, may be used for chickens to drink, or for mixing with their meal, while skim milk may be employed in the preparation of any form of paste, and thus for mixing with dry meals for fowls of all descriptions. The best method of supplying milk food to chickens is in the form of *curd*. A small quantity of rennet in a little water is added to milk at about 85° F. Having coagulated, the curd is drained—the surplus water is removed to a very large extent—until it is sufficiently solid to handle and to break up and distribute to the birds. There is no food so valuable as curd prepared from new milk, nor one better adapted to secure the rapid and healthy growth of young chickens, who may receive it until they have reached adult age.

TRUMPET, CORNET, & HORN

Construction and Characteristics of the Instruments. Scales. Intervals. Exercises. Transposition

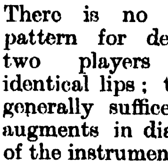
THE TRUMPET

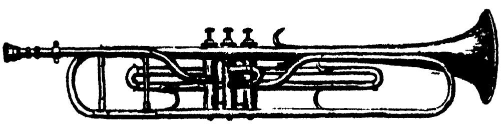
By John Solomon, A.R.A.M.

Of trumpets there are six recognised varieties. First we have the "Bach," expressly employed for that master's works; secondly comes the slide instrument, rarely used nowadays; thirdly we have the C trumpet, identified with French concert orchestras; fourthly there is the B♭ model, employed in German and English orchestras, besides military bands; fifthly there is the E♭ trumpet, requisitioned for cavalry bands and other military purposes; lastly, for the concert platform, the coming instrument in this department is the trumpet in F. Whether for tone-qualities or facilities in manipulation, it surpasses in excellence the other varieties. From C, second space bass clef, to G, above treble staff, it produces a true chromatic scale. Beyond this range other notes can be articulated, but they are rarely written for by composers.

The F instrument thus has a compass of two octaves and a fifth. The length of brass tubing of the trumpet in F is about 68 in; without the F crook it is 72 in. in width. It is provided with three pistons. When these are pressed down and no crook or slide is employed, the first valve opens up about 10 in. of extra tubing, the second approximately 5 in., and the third about 14 in. These valves are fingered either singly, in couples, or all together. Only for the C♮, second space bass clef, are the three invariably pressed down. Lowering the first piston transposes the open sounds a whole tone, the second transposes them a semitone, and the third a tone and a half.

The Mouthpiece. The mouthpiece has an important influence on the tone; it therefore merits consideration. The shape of the rim, cup, and bore each has a material effect. If the rim is too narrow, it is apt to cut the player's lip and fatigue him quickly. It should never be less than $\frac{5}{32}$ in. in diameter. The bore must be hemispherical. If too deep, high notes will be awkward to obtain. There is no standard pattern for depth, no two players having identical lips; the $\frac{1}{2}$ in. generally suffices. From the cup, the bore augments in diameter, so as to fit the tubing of the instrument. Medium gauge of bore should be chosen by the student, although certain lips get a better effect from a small gauge, whilst others excel with a large one. If, however, the bore is too large, upper notes become difficult, whilst if it is too narrow, the low notes suffer.





THE TRUMPET [Mahillon & Co.]

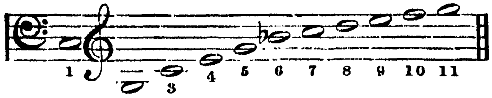
Tone Delivery. The French term for mouthpiece is "embouchure" This word is applied in English to indicate the method of blowing or the efficiency of the lip. In their natural state, a beginner's lips are helpless at the trumpet. Their nerve-sense has to be specially trained. This is only possible by constant practice, until the ganglions are so cultivated that the nerve-fibres respond instantly, by contracting or expanding, at the will of the player. Ordinary soft lips cannot give a true embouchure. The process of strengthening necessitates persevering study. To produce a musical sound from the trumpet, slightly part and draw back the lips without distending the cheeks. Place the mouthpiece of the instrument against the lips, covering more of the upper than the lower labium.

Avoid pressing the mouthpiece on one side of the mouth. Some beginners form their embouchure in this way. It not only looks bad, but should be avoided for other reasons. The proper place for it is at the centre of the lips. Press the mouthpiece gently. Without removing it from the lips, draw in the breath at the corners of the mouth. The first note obtained should be C, first ledger line below staff, treble clef. To produce that tone correctly, withdraw the tongue slightly from the lips with a quick movement, as if expelling a particle of fluff from the tongue-tip. For this note no pistons should be used. If the blowing is done judiciously, a displacement of the air will be caused, and the correct sound result. Practise this C several times. Try to get it more and more distinctly. Gradually, as the lips strengthen themselves, so will the tone improve.

The Harmonic Scale. In the F trumpet there are eleven open notes, or natural harmonics, as in Example 1.

Here the sixth note is flat and the tenth sharp. By the use of the first piston these sounds come in tune with the others. Other notes are obtainable, but are not required in written parts. For the purpose of altering the key in which a piece is printed curved tubes are inserted into the trumpet. These are called crooks. According to their length, so are they lettered. First we have the F crook, 4 in. long; secondly there is the E♮; thirdly, the E♭; fourthly, the D♮, followed by the D♭, C, B, B♭, and A. Each one thus descends half a note at a time from the F, an extra length of tubing being added and coiled, for the sake of convenience, oblong fashion. In all, there are ten crooks written for by composers. The D♭ and B♮ crooks are rarely used, and the majority of them are seldom employed, since the player finds it more easy to transpose without their aid. The student should therefore learn to play with the F crook only, transposing the music by means of the pistons when other crooks are indicated. This is the safest plan. The only crooks usually made, therefore, are the F, E♮, E♭, and D. If those for other keys are required they have to be manufactured specially.

Ex. 1.

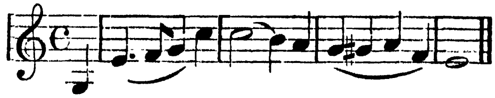


Valve Mechanism. Valves, or pistons, were unknown before the year 1814. Prior to that time the trumpet was simply a coiled tube enlarged at the bell-end. Towards the close of the eighteenth century a slide was added to the trumpet, working in a reverse direction to that associated with the trombone, being drawn towards, instead of extended from, the player. Nevertheless, a good chromatic scale could not be produced. The slide was insufficiently long to give the low A♯, A♮, and C♯. F♮, also, was too sharp. Nowadays, instead of the slide, we have three pistons. When pressed down separately or together, these are capable of rendering a perfect chromatic sequence. Each piston gives parallel harmonics to those sounded when no piston is employed, the same notes being heard but in a different key. A similar effect results when the pistons are combined, whether the first and second, the first and third, the second and third, or all three are put down together in order to lengthen or shorten the passage of air in the tubing. With the first piston down, the series already given is reproduced, but lowered in pitch a tone. Instead of F, the key thus becomes E♭, and the sixth and tenth degrees need correction in the same way as when the open harmonics were sounded without using the pistons. Releasing the first and depressing the second piston, the same series, as the air-column is shorter, becomes a semitone higher. So the natural key is now E, with four sharps. If only the third piston is pressed down, the tone is lowered a third from the open series. The key is, therefore, D♮.

These results should be understood clearly, as they introduce the subject of transposition. So the beginner must bear in mind that the trumpet, when open, is in F; when the second piston is down it is thrown into E; that the first makes it E♭, and the third D. Pistons are here, it will be seen, taking the place of crooks.

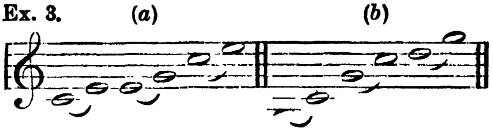
Slurring and Phrasing. Slurring implies, when playing on a wind instrument, making the sound glide from one note to another without fresh impetus from the tongue. This effect is indicated by a curved line above or below notes required to be linked in such a manner, as in Example 2.

Ex. 2.



When a slur is not marked, notes, in trumpet playing, have to be tongued, as already described. For the beginner, difficult intervals to slur, whether open or with pistons, are thirds, fourths, fifths, etc., as in the following example.

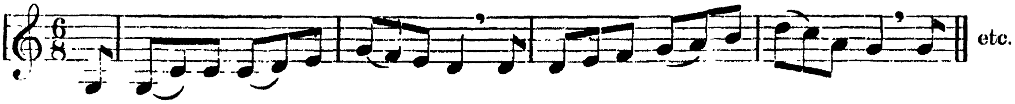
Ex. 3.



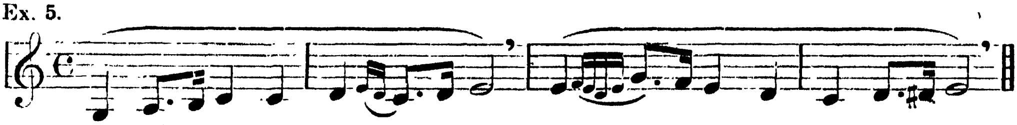
For them, therefore, special practice is needed. Phrasing comes almost under the same heading in performance as slurring. The difference is that the student must understand the correct moment for taking a breath when rendering a musical sentence. Those places are shown by commas in Example 4.

It will be seen here that a slur is included also in each phrase. If these slurs were omitted, all the notes would have to be tongued. This, in solo playing, would give a rough and staccato effect. Another way of writing a phrase containing a slur is shown in Example 5.

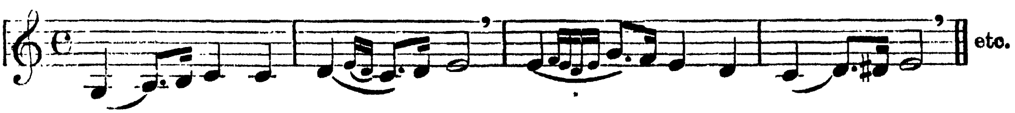
Ex. 4.



Ex. 5.



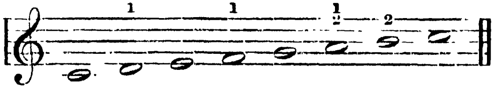
Ex. 6.



The curved line above each of the two bars, connecting the notes, implies that the tongue must not be used too freely. The phrase will be broken up if breath is taken at other points than those marked. As regards the slur placed under the notes, those not so linked must be tongued, as shown in Example 6.

Transposing. To the beginner, one of the first puzzles is to reconcile a note indicated in the written music with a different note sounded by the trumpet. Thus, G, written on the second line treble clef, played on a B♭ crook, transposes itself a fifth lower to middle C, as do all the other notes when that crook is indicated. If the F trumpet is crooked in E♮, the same written note, G, when played, becomes F♯, a semitone lower, an effect more conveniently given by depressing the second piston. If the notation indicates an E♭ crook, the player—or the instrument—transposes a note lower. The G then becomes F♮, and so on. Should the part be marked in D, it must be transposed a third lower. As we have shown, each successive crook lowers the pitch half a tone down to A♮. The best way to learn to transpose trumpet music is to take a scale and start in F. With this F crook, practise an octave in C major, putting down the first and second pistons on the second, fourth, sixth, and seventh degrees, thus:

7. (F Crook).



If these notes were preceded by the words "E crook," that would necessitate transposition a semitone lower, when the sounds would be

Ex. 8.

Thus, the scale becomes B♮. The occurrence of five sharps may make transposition appear difficult. To put the crook into F♭ would make it extremely difficult to transpose quickly. It would bring all the notes into flats, so this is better left alone and the E♮ that is written for only used. If the same part is marked "E♭ crook," the notes have to be transposed a tone lower from F. Thus, the starting note, originally C, becomes B♭, and that key has two flats. When the D crook is indicated, transposition likewise must be a minor third lower; with the C crook a fourth, B♭ crook a fifth, and the A♮ crook a fifth and a half, or minor sixth, lower. Although an exceedingly awkward transposition, the latter is frequently employed by modern English and Russian composers. British musicians often write for the trumpet in B♭ and A♮, because there are few F trumpet players and many B♭ performers. This not only saves the latter the trouble of transposing, but keeps parts from being disfigured with transposition marks. The F trumpet student is advised at first to practise perseveringly very low scales. In this way he can familiarise himself with transposing the music, using the pistons according to the indications for the different crooks. The scale of C will soon become familiar in every key if he does this. Then he should take a short, easy exercise and practise it in the same way. Next, he is recommended to get an oratorio trumpet part and transpose that also into the different crooks. With average ability, in a short time the result will be satisfactory. We give, as an illustration of such simple transpositions, a few bars on open notes only [Example 9].

To transfer these sounds from F into E♮, depress the second valve. This lowers the pitch equally half a tone. The effect, therefore, is as shown in Example 10.

The same passage "crooked in E♭," a note lower than F, would begin on D♮. Therefore, put down the first piston. As in the first instance all the notes were open, the same sequence will now be obtained. But the D (written on the fourth line) sounds flat with the first valve down, and the effect is better open. As it is then the natural open C on the F trumpet, it follows that it must be in tune for the D crook. Now try the crook in C. Begin on B♮, and transpose a fourth lower. For this series the piston must be used, otherwise the notes will not be in tune, and will sound too sharp.

For the B♭ crook, transpose a fifth lower, beginning on A♮. The student will find the study interesting if he tries short exercises in the same way.

Exercises. So far, not many tutors have been published for the F trumpet, as its beauties have hitherto not been fully appreciated. The exercises on the next page give, first, the fingering of the entire range of the chromatic compass, flats in descending being manipulated in the same way as sharps in ascending [Ex. 11]. It is of great importance, in order to get smoothness and the ability to sustain the tone of the instrument, that slow

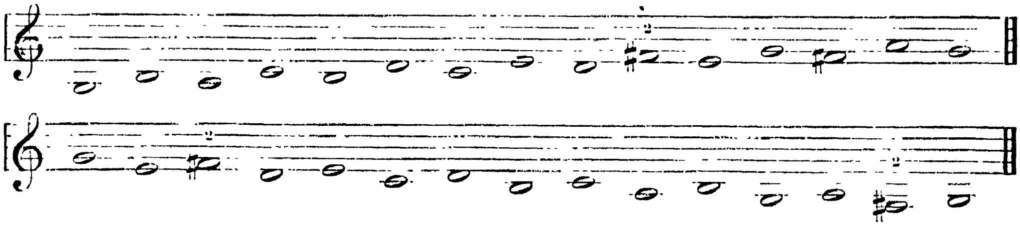
Ex. 14



scales should be practised carefully every day. Although the beginner will not, of course, be able to negotiate extremely low or high notes, these will not present so much difficulty when the embouchure has been strengthened by diligent study. **Ex. 12** can be fingered by reference to Ex. **11**, and extended an octave higher by blowing with a firmer lip. It is merely the normal diatonic scale, and should be transposed into other keys. To acquire facility in the accurate articulation of any sound which occurs in a musical phrase when reading at sight, constant exercise in the practice of intervals is essential. Here Ex. **13** deals with seconds and thirds, which can be extended higher up and lower down the compass. With its sharpened F's Ex. **14** indicates the key of G major. **Ex. 15** deals with fourths, Ex, **16** with fifths, which, although unmusical when blown consecutively, are useful to be able to attack at sight without hesitation. Ex. **17** gives sixths, Ex. **18** sevenths, and Ex, **19** is an octave study. Of all intervals, that which separates eight notes is the most interesting, since it represents the most perfect consonance in music. In painting, it is as if one saw a picture side by side with an exact facsimile reduced to half the original size. The tone-relationship of the higher and lower sounds are the same, but the vibrations, owing to the greater force of the breath, are more rapid in the octave above than in that below.

THE CORNET

By John Solomon, A.R.A.M.

The cornet-à-pistons, introduced about the year 1850, are now common to all military and brass bands, as well as concert orchestras. The cornet differs from the trumpet, not alone in appearance but in tone, its tubing being of wider gauge, and conical rather than cylindrical. It is usually modelled in B♭. Cornets are also made in C, but are only purchased by amateurs, to save transposition when accompanied by the piano. The instrument is of brass, the length of the tube being about 54 in. This gives the natural harmonics of B♭.

The cornet is provided with three pistons. These, as in the trumpet, lower or raise the pitch of the open notes according to the way they are employed. When the first piston is depressed, it transposes the open G, second line treble clef, a tone lower, to F. If the second piston is put down alone, the G is transposed half a tone, to G♭ or F♯. The third piston, by opening up more tubing, lowers the G an interval of a third, to E♮. The tone of the cornet is pleasant if not overblown, as in very loud playing. Owing to such a tendency, the instrument has received a bad name. Nevertheless, an artist can make its quality expressive and most delightful to the ear. Although the cornet can be made to sound in a way closely resembling the orchestral trumpet, there is, as a rule, a vast difference between the effect of the two instruments, on account of the dissimilarity in their tubing. To begin with, the B♭ cornet is pitched a fourth higher than the F trumpet.

But when crooks are placed on the latter instrument to lower the tone, this sounds more mellow, owing to the length of the air-column. On the other hand, as the shorter tubing of the cornet produces a tone of a higher pitch, it is brighter and more brassy. So the trumpet, if made above the key of F, would lose its proper character through shortening the air-column. Be careful, when purchasing an instrument, to see that it is free from faults, such as, usually, cracks, bad corks, wrong springs, or leaky valves.

The Mouthpiece. Much depends upon the shape of the rim, cup, and bore of the mouthpiece. The rim should neither be too wide nor too narrow; medium size is best. The cup must be conical but not shallow, like that for the trumpet. When buying an instrument, try several mouthpieces, and get that most suitable. At first there may be some difficulty in this. If the rim is not plated, it must be kept scrupulously clean. Before putting away the cornet, always wipe the mouthpiece carefully. See that there are no green spots on the brass. If they appear, they are caused by verdigris. Should the lips be sore, the result may be serious, and it is far wiser to purchase a plated mouthpiece. When once simple notes can be obtained with ease on the mouthpiece selected, practise steadily with it until the lips form a good embouchure. When this is once obtained, no after-adjustment will be necessary, as is the case with reed instrument players.

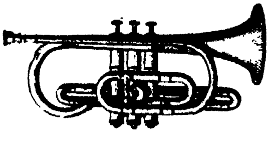
Tone Production. The method of producing sound from the cornet is the same as that for the trumpet. The first note to be obtained without touching the pistons is G, second line treble clef. Then get the C below the G and the octave C above. Sustain such sounds whilst mentally counting four very slowly. The other open harmonics should then be practised. When the open notes can be produced with ease, the pistons may be used. Try them singly at first.

Putting down the first piston, get the F, first space treble clef, clearly. Then sound B♭ on the third line above. Follow it by the octave B♭ below, and so on. In the same way obtain the harmonics from the second piston only. When these have been accomplished the student will be able to play the scale of C, using the pistons. What is known as the embouchure (described in the article on the Trumpet) signifies the flexibility and power of the lip in eliciting any sound required. Having acquired the ability to play the scale in C, if other scales together with exercises are regularly practised, the lip will strengthen gradually, and a good embouchure result. Avoid distending the cheeks.

Natural Harmonics. Owing to the air-column being shorter than in the trumpet, the cornet has a more limited compass [Example 1].

Except by great soloists—and then only for show purposes—the fundamental harmonic, or bottom C, is never used. Again, No. 7 (B♭) is not fingered as an open note, its effect being better when played with the first piston down. The extreme harmonics, Nos. 9 and 10, are seldom employed. Exceptional players, however, get even higher sounds than these. But the normal compass of the cornet is from F♯, on third ledger line below treble clef, up to C, on second ledger line above the staff. Only on rare occasions is the D above required.

Shanks. In place of the crooks on the trumpet, the cornet has two shanks. These are in B♭ and A♮. An A♭ crook was formerly used, as well as a G crook. These are now obsolete. As the cornet is modelled in B♭, the B♭ shank can scarcely be called an addition. It is a part of the instrument, but its use is convenient. It saves the player's face coming in contact with the body of the instrument. Without this shank, the cornet would be nearly half a note sharper in pitch. The A shank, being longer, transposes the instrument half a tone. Middle C, when the B♭ shank is adjusted, thus gives B♭ on the piano. The same note, with the A shank, sounds A♮ on the keyboard. Flat keys are generally played most easily with the B♭ shank, and sharp keys when using the A♮ shank.



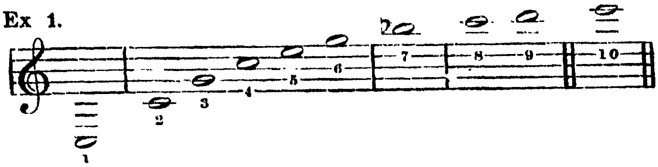
THE CORNET [Mahillon & Co.]

Valve Mechanism. The use of pistons came in about the year 1814. In 1832 an instrument appeared called the stop-trumpet, or cornopean in B♭. This gave the natural harmonics. It had three valves, or pistons, and the power of lowering the open notes six semitones, as in the valve trumpet. To-day the first piston, when pressed down, transposes a whole tone, the second a half-tone, and the third lowers the open sound a third. Yet this is not always the case. For example, certain notes in Example 2 can be obtained by pressing down the first valve.

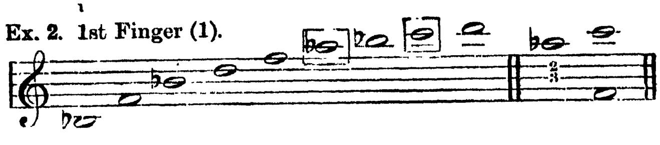
The notes bracketed on the sixth and eighth degrees, not being in tune, are better produced when the A♭ is fingered with the second and third pistons together and the C is played as an open note without touching the pistons. When the second valve is lowered, the series shown in Example 3 results.

Here, G♯ and C♯, not being in tune, are fingered respectively by use of the second and third and first and second valves. When the third piston is lowered, the sounds indicated in Example 4 can be obtained.

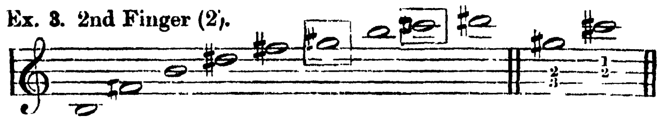
Ex 1.



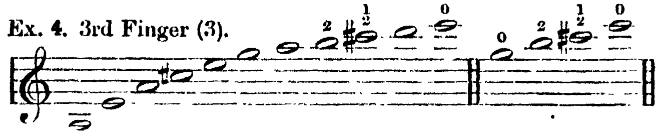
Ex. 2. 1st Finger (1).



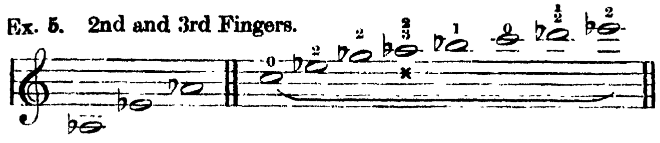
Ex. 3. 2nd Finger (2).



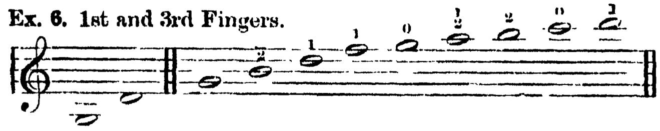
Ex. 4. 3rd Finger (3).



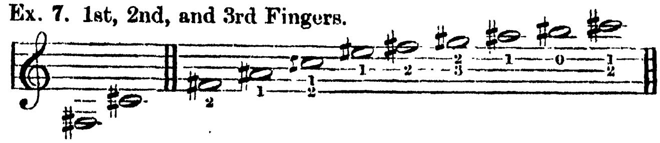
Ex. 5. 2nd and 3rd Fingers.



Ex. 6. 1st and 3rd Fingers.



Ex. 7. 1st, 2nd, and 3rd Fingers.



In this series, four notes need tempering. By the alternative fingering indicated they are produced correctly. When the second and third pistons are pressed down, the eleven sounds shown are possible, but as, after the first three are obtained, the others are not in tune, it is better to finger these in the way marked in Example 5.

When the first and third pistons are depressed, the notes indicated in Example 6 can be sounded.

Here, again, after the first two, the others are better fingered in the usual manner. When the three valves are pressed down, the harmonic series shown in Example 7 is obtained.

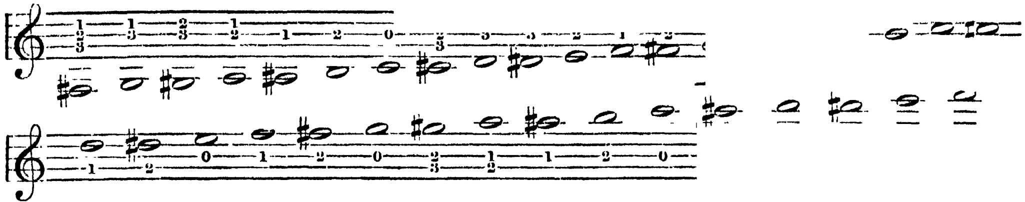
As will again be seen, only the first two notes in this sequence are satisfactorily produced by all three pistons. The others should be fingered as marked. In the next example, as a guide to the student, we show the entire chromatic scale, or series of notes elicited from the cornet. Flats, in descending, are fingered as are the sharps in ascending. The five highest notes are seldom required. Nevertheless, we give them, since modern composers think little of trespassing beyond the recognised compass. Beginners, however, should not, in playing, venture beyond the top C [Example 8]. If they do they may injure their lips.

Slurring and Phrasing. As the cornet is a solo instrument, correct slurring and phrasing upon it are even more important than in trumpet playing. As explained under Trumpet, a slur is a line placed over or under certain notes, linking them together, so that they are rendered smoothly [Example 9].

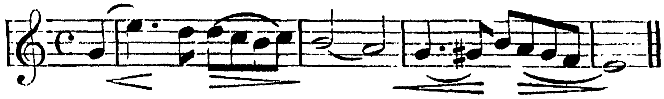
When a song is adapted as a cornet solo, study the words. If these are understood and remembered, the slurring will be assisted, and the piece performed as it would be sung, the player taking breath and phrasing in the same way. Slurs on open notes, as also those given by valves, will be found difficult at first. Especially is this the case with intervals as in Example 10.

For the mastery of such difficulties, several weeks may be necessary, but unremitting practice will overcome them. Every fresh slur, however, may not admit of a fresh inhalation, because one breath has to suffice for a whole phrase, or musical sentence. Slurring, therefore, is subordinated to phrasing, although the former bears an important part in a long passage in which many notes may be slurred, the others being separately tongued. To phrase well, the student should endeavour to sing upon the instrument. This is impossible without paying constant attention to the art of phrasing. Unless a solo is phrased, it is apt, on the cornet, to sound vulgar. Instead of being vocal, the effect is harsh and crude. So the breath must only be taken when a phrase ends, or before it begins. To do this artistically needs experience. In some cornet music, phrase marks are printed. In the majority of solos this is left to the judgment of the performer.

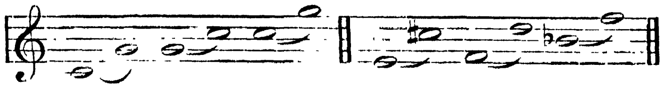
Ex. 8.



Ex. 9. *Andante.*



Ex 10.



Transposition. Cornet players in an orchestra are expected to be able to transpose at sight. Horn and trumpet parts are frequently handed to them by the conductor to interpret in this manner. The beginner, therefore, is advised to accustom himself to transposing any scale or small piece. First transpose a note higher, then two notes, and so on up to a fifth above. Supposing that the trumpet part to be read by the cornet is crooked in C, the cornet should then have the B♭ shank. With this on, read a note higher. This makes the key D, with two sharps, instead of C, without sharps.

Remember, always, when accidentals occur that sharps must be read as naturals, naturals as sharps, and flats as naturals. Think of the key into which the music is being transposed. As the trumpet part crooked in C is being rendered by a cornet in B♭ a note higher, it must be borne in mind that every F and C in the key of D is sharp, the E♮ and B♮ in the trumpet parts becoming F♯ and C♯ on the cornet. If the trumpet is crooked in D♭, and the cornet is in B♭, a minor third higher, C, third space treble clef, will become E♭ on the fourth space, and that key has three flats, B, E, A. If the trumpet is crooked in D♮, the cornet must then have on the A shank. The transposition, therefore, will be a fourth higher, and C on the third space will then be read as F on the fifth line, with one flat, B. Here the note F, whenever it occurs in the trumpet part, represents B♭ in the cornet.

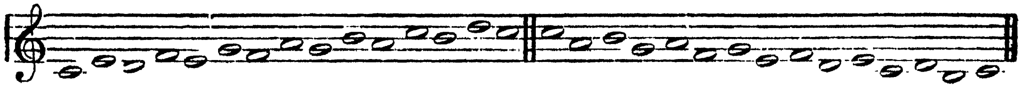
If the trumpet is crooked in E♭, put on the B♭ shank. Read a fourth higher, as in the last instance. If the trumpet part is crooked in E, use the A shank and read a fifth higher. C, third space, then becomes D above staff, and G major has one sharp, F. If the trumpet is crooked in F, adjust the B♭ shank. Read a fifth higher. The same sounds will result as in the last instance. It will therefore be seen that, in transposing a fourth and a fifth, both crooks, used alternately, give the same tonal effect.

When horn parts have to be transposed, it is necessary to read below instead of above. To do this most players mentally transpose the notes upwards, and play them an octave lower, since the horn, having nearly double the length of tubing of the cornet, voices all notes at a deeper pitch. Thus, if C, third space treble clef, is written for the horn crooked in F, to render suitably that note on the cornet the B♭ shank is affixed. The sound is transposed mentally a fifth higher, to G above the staff, and played an octave lower; or it may be read at once a fourth lower than written. In either case the sound heard is G on the second line.

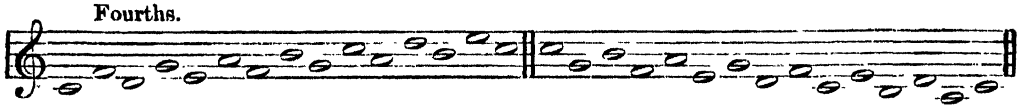
As trumpet parts have to be transposed upwards, the majority of cornet players, when horn parts are given to them, find it easier to make, mentally, the usual ascending transposition and then play an octave below, rather than transpose down at once. If both methods are attempted, momentary forgetfulness in reading at sight may lead to a blunder. Yet there should be no more difficulty in transposing down than in transposing up. It is only a question of practice. To acquire equal facility in either method, the student must start at an early age. He is not likely, otherwise, to master both principles in a way to be depended upon. Therefore, practise systematically both methods. Begin, however, by transposing each note in the scale of C, first one tone, then three tones, a fourth and a fifth higher. If transposition is neglected at the beginning of cornet study it is more difficult to acquire later. Its importance for professional purposes cannot be too much emphasised.

Studies. The cornet method most in use is that by Arbon. It begins in the simplest way, and advances gradually to the most difficult studies a player is likely to need. Tutors by Kosleck, Bonniseau, Forrestier, and Saint Jacomb are well known. The latest and best publication at the time of writing is by Hermann Pietsch. It is published in English as well as German, and is issued in two parts. The beginner is advised to play all exercises very slowly at first. Make sure that each note is correct in pitch and of good quality. Attention must be given daily to mastering the scales. Interval practice should follow. This must be done systematically. From the note C, first ledger

Ex. 11. Thirds.



Fourths.



line below staff, play in intervals of thirds, fourths, fifths, etc., up to octaves [Example 11].

If the student desires to excel, the study of intervals is essential. He must get accustomed, first, to hearing the sounds. As one piston produces several sounds, the ear must detect the right one, and the lip blow it instinctively. In this matter beginners are frequently careless. The habit easily grows upon them. Unless mistakes are pointed out, they are themselves ignorant that wrong notes are being sounded; therefore, begin all new exercises slowly and listen carefully. When sure that the notes are correct, the time can be accelerated. Transpose the same exercises into other keys, always playing slowly at first. Afterwards, the semibreves can be played as minims, then crotchets, quavers, or, finally, as semiquavers. When the student is sufficiently advanced for solo playing, slow melodies, such as easy songs, are advised. These, and other simple cornet pieces, can be obtained cheaply.

Double and Triple Tonguing. Double tonguing implies two notes repeated quickly, as if the syllables "tu-ku, tu-ku" were pronounced [Example 12].

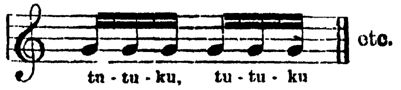
Ex. 12.

tu - ku, tu - ku. etc.

Some players reverse the words.

To triple tongue, or repeat three notes rapidly, the syllables employed are "tu-tu-ku." Some teachers prefer "tu-ku-tu," but the sounds are surer and more even with the former method. Again, begin slowly. Try this example:

Ex. 13.



When these notes are properly sounded, beginning in slow and ending in quick time, and are articulated equally, another note should be treated in the same way until triple-tonguing is accomplished on every degree of the scale.

As the cornet is the leading brass instrument in a military band, there is a tendency for many beginners to take up this most popular of wind instruments. Thus the supply of players often exceeds the demand; but for orchestral engagements conductors naturally select only recognised artists of proved ability.

In conclusion, the student is advised not to be in a hurry. To become a first-class cornet player is a long and arduous undertaking. Great care must be exercised against the contraction of bad habits. When beginning a new study, four long beats should be counted on slow notes, to make sure that the sounds are correct.

THE HORN

By Paul Corder

Before taking up the study of the horn (it is also known as the *French horn* and the *valve horn*) the student should understand something of the principle which underlies the production of sound from those brass instruments of which the horn, trumpet, and trombone are the most important types. All the instruments referred to, besides many others, consist of a tube of metal (brass being most frequently used) of conical bore—that is, larger at one end than the other. Let us inquire briefly into the acoustical properties of such tubes.

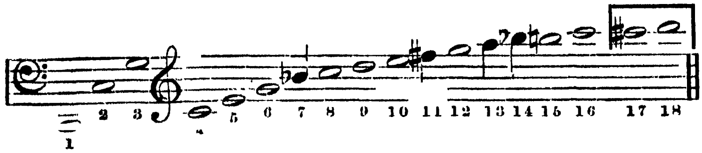
Taking one with a length of 8 ft., it is found that, on putting into vibration the air contained within the tube, the note  is produced. This is termed the *fundamental* note of that length of tube, and were it the only note capable of being produced from it, the tube would be of little use as a musical instrument. But it is possible to make the column of air divide into two equal parts, each half vibrating independently; the note now sounded is the C an octave above the previous sound. Furthermore, the air-column can be made to vibrate in thirds, quarters, fifths, sixths, and so on, the notes produced in each case being shown in the illustration at the top of the next page.

Those notes written as crotchets are imperfectly in tune, and the last two are very difficult of production.

This series of notes is termed the scale of natural harmonics, and constitutes what are known as the open notes of the horn.

Now we may leave generalities and come to a more particular account of how these facts apply to the horn. The tube of which it is composed is, on account of its extreme length, coiled up into a convenient form. One end opens out abruptly into a wide "bell," the other is fitted to receive the mouthpiece or extra lengths of tube. The mouthpiece is a conical brass tube, the exact shape and bore of which varies according to circumstances; for facilitating the production of the higher harmonics a slightly smaller bore is advisable than would be preferred for the lowest notes.

The Crook It will be seen on reference to the table of harmonics that only a limited number of notes is possible on this instrument, and if the music should be in any other key than C, still fewer notes are available. This drawback was partially overcome by the use of a series of extra coils of tube, called *crooks*, which, by adding to the length of the horn, lowered the

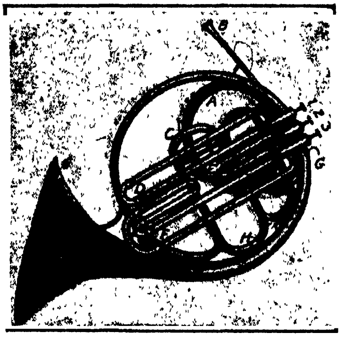


pitch of the fundamental note and consequently of all the harmonics to a corresponding extent. Thus—the body of the horn has a length of 7 ft. 4 in.—by adding a tube about 8 in. long, called the C alto crook, the series of notes already given will be produced. A crook 55 in. in length will cause the whole series to sound a fifth lower; this is called the F crook (F being now the fundamental). One in C basso increases the length to 16 ft., and lowers the pitch a whole octave. In the same way crooks of any length can be made to pitch the horn in whatever key is required.

Now, since the pitch of the notes is determined by the crook in use at the time, the player blowing the same relative series in any case, the custom arose of writing always for the horn as if in C alto, previously directing which crook was to be used. This saves the player the trouble of transposing, although it is woefully puzzling to the student to find the written notes meaning anything and everything at random. For this reason the matter has been explained at some length, as, since the modern innovation of valve mechanism, the older customs of crooking and transposing seem useless and meaningless; for the horn in use at the present time has none of the drawbacks attendant on the old "hand horn," as it was called, the gaps in the harmonic series having been filled in by means of an ingenious mechanissm which may now be briefly described.

A short length of tube is interpolated in such a way that, on depressing a piston attached thereto, the air is diverted through this extra tube in the course of its passage through the main coil of the horn. This is, in effect, temporarily increasing the length of the horn and lowering its pitch. On raising the piston, this extra tube is cut out of the circuit, and the original note restored. The modern instrument is provided with three of these devices, the first lowering the pitch a whole tone, the second a semitone, and the third three semitones, while any two can be used in combination or all three together; this last will lower the pitch to the extent of six semitones. It will now be readily understood how a complete chromatic scale can be played throughout the compass of the instrument.

So far we have spoken only of what the horn is capable; it remains now for the student to learn how it is possible to set in motion this column of air so as to produce any note required of the harmonic series.



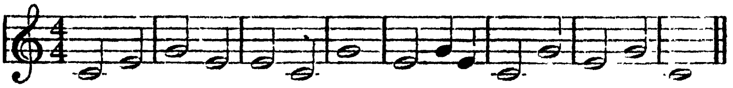
VALVE HORN

The illustration shows a valve horn by Cortois and Mille. The coil marked A is the F crook, B is the mouth piece, the piece marked C is made to slide out in order to tune the horn to the exact pitch in use. If the course of the tube is followed from the bell, it will be seen to divide into two at H. This is not actually the case, as H is merely a strut to strengthen the pipe, and has no air-passage through it. The three pistons are numbered 1, 2, 3, and attached to them are their tuning-slides, marked respectively D, E, F.

The horn is held thus: the little finger of the left hand is passed under the hook G (in some instruments a ring is substituted), the other three fingers are thus brought into position over the three pistons, while the thumb is passed through the coiled tube and braced in a convenient position. The right hand is to be arranged as compactly as possible, the fingers close together, the tip of the thumb resting along the front of the forefinger, the whole hand slightly curved, and then inserted in the bell of the instrument as far as it will go.

The important matter of the arrangement of the lips, or embouchure, as it is termed, now claims attention. A description of this is anything but easy. It may, however, be stated that it is useless to blow through a horn as you would through a whistle; neither should the cheeks be distended; on the contrary, they must be drawn in until the muscles on either side of the mouth are felt to be exerted. The lips are drawn together so that the air issues from them by a small aperture under considerable pressure, which pressure is regulated by the muscles of the cheeks and lips. The tongue and the upper teeth form a kind of valve, by means of which the compressed air can be retained in the mouth and lungs independently of any assistance from the lips. By pronouncing the syllable "ta," a thin stream of air will be released and allowed to issue from the lips.

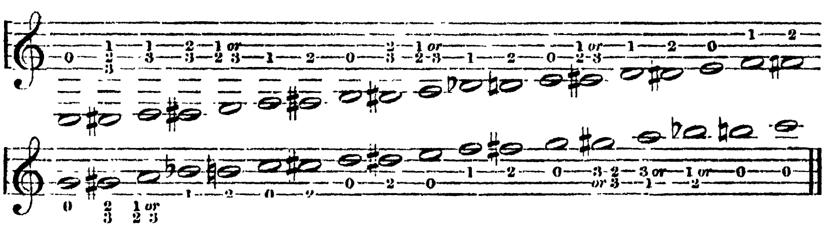
A first attempt to produce a note from the horn is fraught with considerable uncertainty. Very possibly no sound at all will be forthcoming, but by careful experimenting, and making slight alterations between the relative positions of the lips and the mouthpiece, a sound of some sort will eventually evolve itself. We want, for a first attempt, to produce the note C, first ledger line bass clef, sounding, of course, a fifth lower if the F crook is being used. Let the student keep this sound in mind, and try to reproduce it. It is more than probable that he will make some entirely different note, perhaps B♭. This is caused by too great an air-pressure; leave the lips and cheeks looser, and try again. It will not be long before he attains the adjustment necessary for the required sound. Having gained this first step, a very slight increase of pressure will give E, first line treble clef, and a little more the G above, and with these three notes the student should rest satisfied for the first lesson, turning them into an exercise, of which the following may be taken as a specimen :



When a certain amount of mastery over this and similar exercises has been attained, the compass may be extended by the addition of C, third space treble clef. The greater pressure required for this and higher notes is obtained partly by tightening the lips and compressing the cheek muscles, and partly by forcing the mouthpiece against the lips by means of the little finger of the left hand. In striving for this C the student may possibly sound B♭ at times, but this note should be avoided, as it is imperfectly in tune and is seldom used as an open note by horn players.

Before making any use of the pistons, the student should extend his acquaintance with the open notes until complete facility is obtained over this series :

The low C will probably give considerable difficulty in production, and may necessitate a complete change of embouchure, as the lips require to be very loosely arranged. It will be noticed, also, that after practising the higher notes the low ones are more difficult of production, and when the low ones have been practised the high notes become proportionately difficult. This is caused by the great difference of embouchure between the extreme notes of the horn's compass, for which reason the first horn in an orchestra seldom goes below C, first ledger line bass clef, and the second rarely rises above C, third space treble clef. Of course, a solo performer must acquire, by constant practice, equal facility over the whole compass.



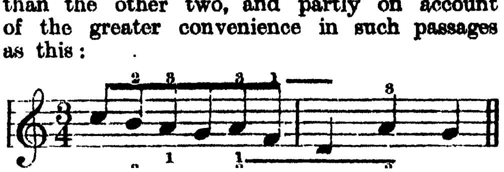
It will be remembered that the fundamental note is an octave below the low C already spoken of; but this note is scarcely possible, except on the higher crooks, and even then it is so weak and uncertain as to be practically useless. On the other hand, the notes above the high G, as far as C, second ledger line treble clef, are quite possible, although difficult, and should be diligently practised by the student who aspires to play "first horn." They will be found somewhat easier if practised at first on a lower crook, say, E♭, but may afterwards be played on the F crook. The very greatest pressure required for the top C is obtained in the manner previously described, but in a greater degree.

It should be mentioned that the bass clef is sometimes used for the lowest notes, and much confusion has resulted from the practice of the older composers, when so doing, of writing an octave lower than the part is to be played. This senseless custom has now been abandoned, and modern composers intend their music to be played as written, whatever clef they use.

At this stage the ambitious student should procure a book of further studies and exercises. Oscar Franz's "Wald-horn Schule" can be confidently recommended; it has, however, the disadvantage of being written in German, although this in no wise affects the studies contained therein. The horn parts of standard classical works will likewise afford excellent practice. The symphonies of Mozart and Beethoven, and many others works of about the same period, were written for the horn without valves, and therefore contain almost entirely open notes.

The Valves. It is now time to make use of the valves, by means of which, as has already been explained, a complete chromatic scale can be obtained throughout the whole compass. The fingering for this is shown in the illustration below.

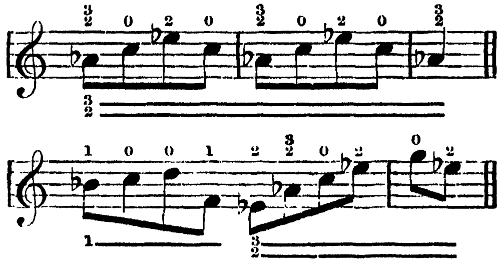
It will be noticed that for certain notes there is a choice between the first and second fingers in combination with the third, either fingering lowering the pitch three semitones. Most horn players seem to prefer the 1 2 fingering, partly because the third finger is less agile than the other two, and partly on account of the greater convenience in such passages as this :



[The line indicates that the finger is to be kept down.]

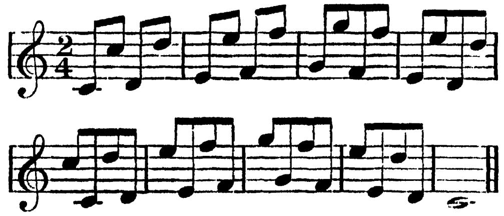
If the third piston were used here it would be necessary to raise it simultaneously with the depression of another, which might impair the smoothness of the passage, whereas, by using the lower fingering, only one movement at a time is necessary.

Furthermore, a little consideration will show that many notes have several possible fingerings. The B on the third line may be lowered from the open C by the second piston, or from the D by the third, or from E by the first and third. It is impossible to make any rules for the employment of these additional fingerings, their use being solely a matter of convenience, but an example or two may serve to indicate their usefulness. At the top is shown the ordinary fingering, that given below shows the simplicity attained by the alternative fingering.

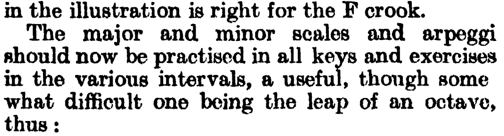


The valves are provided with sliding pieces of tube for the purpose of tuning, according to the crook in use; the lower the crook, the more extended must be the slides. The position shown in the illustration is right for the F crook.

The major and minor scales and arpeggi should now be practised in all keys and exercises in the various intervals, a useful, though some what difficult one being the leap of an octave, thus:



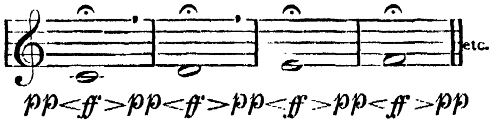
Slurring and Phrasing. A few words will be advisable on the subject of slurring and phrasing. It has been shown that a note was produced by pronouncing the syllable "ta." This has the effect of giving the note an accent, or "attack." But one note may be made to glide into another without any perceptible break by pronouncing (approximately) these sounds:



thus making the vowel-sounds more acute as the passage ascends, and broadening them in a descending passage. It is, of course, possible, and often desirable, to "attack" a note so gently as to entirely avoid an accent. When two notes are slurred together, as in the foregoing example, the second one should be played more lightly than the first, and especially so when the second is the shorter of the two. If the reverse effect were required it would be specially indicated, thus:  implying a *crescendo.*

The student should now endeavour to cultivate a wide range of tone, varying from the beautiful dreamy *pianissimo* to the big "brassy" *fortissimo*, taking care that the air-pressure and embouchure do not alter and so affect the note.

One of our most eminent horn players, before playing at a concert, invariably practises a scale in this manner.



taking breath for each note and holding it as long as possible. It is one of the finest exercises for getting one's lips into good condition.

The Mute. A curious effect is produced on the horn by inserting a suitably-shaped pad or block into the bell of the instrument. This, which is called a *mute*, is indicated in German music by the words "*mit dämpfer*," or in most other countries by "*con sordino;*" or a cross over a note, thus,  is sometimes used instead. Muted horns played *pianissimo* have a curiously faint and far-away sound; played *fortissimo* the effect is not easily described, but it is very different from the open sounds. For isolated stopped notes the horn may be muted with the right hand by bending it over at the knuckles and blocking up the bell.

There is a remarkable want of agreement among theorists as to the precise effect produced by the mute on the pitch of the horn. Before the invention of valves it was customary to fill in the gaps of the harmonic scale "by the insertion of the hand or other obstacle into the bell of the instrument, partially blocking the tube, with the effect of *lowering* the pitch of all the notes a semitone or a tone." On the other hand, another author tells us that "by stopping the bell with a pad the pitch of the instrument is *raised* a semitone." Each of these statements is fully corroborated by other authors. Which is the one to believe? In a sense, both authors are correct. By inserting the hand into the bell the note can be gradually lowered to as much as a whole tone: at the same time, by the use of the mute or hand, it is possible to play a passage a semitone higher than it would sound without this device. The student must remember when playing a passage marked *con sordino*, to make allowance for this alteration of pitch, preferably by keeping the second piston down, when the passage will be lowered to its normal pitch. When a rest of sufficient length occurs in the music, the crook should be removed and the water emptied out of it to prevent any bubbling sound.

LIGHT PORTABLE MACHINES

Electrically Driven and Pneumatic Portable Machine Tools for Drilling, Tapping, Reaming, Expanding, and Riveting

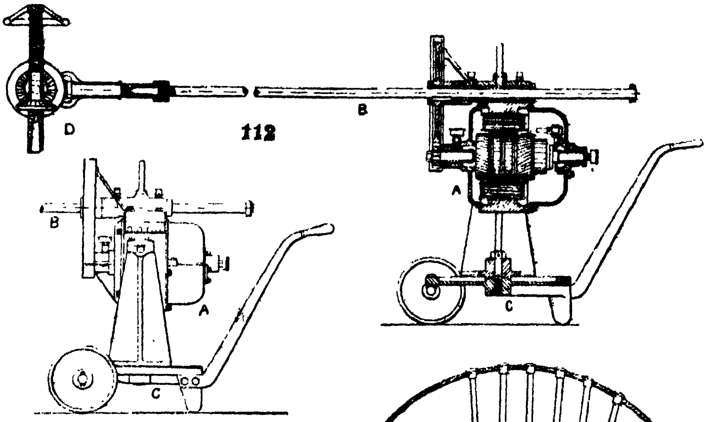
By FRED HORNER

our account of those types of portable machines which are attached to the work, we note the valve-face tools, used for planing-up worn faces when the cylinders are in place. A cast-iron frame is bolted to the cylinder, and it carries two revolving heads, provided with cutters, which rotate as they are slid along in grooves, and so gradually tool the area of the valve-face. For situations where there is considerable freedom, a small portable milling machine with vertical spindle is useful, the spindle being supported in a bearing that slides across a rail bolted above the valve-face. This method also possesses the advantage that by inserting small end mills in the spindle the ports may be trued out neatly and accurately, instead of having to be chipped and filed.

Keyway Cutters. A very valuable class of tool which supplants the chipping and filing method is that for putting key grooves in shafts and wheels. The first kind of machine usually embodies a set of clamps, which are bolted to the shaft, and afford a runway for a bearing supporting a milling cutter, which ploughs out the groove, a drive by handle being usually given. The machine may be carried anywhere, and fastened on a shaft while in place. It is often found necessary in engineers' and other works to add extra pulleys to existing shafting in order to drive new machines laid down, or to suit altered positions. The alternative, then, is either to cut a keyway by hand methods, or to take the shaft down and put it on a slot-drilling machine, which cannot usually be done on account of the trouble and delay to the shop, or to do the job with a portable machine, the last-named method being the quickest and best. In the case of wheels, a portable machine may be occasionally useful; it assumes the form of a bracket-shaped casting holding a reciprocating bar fitted with a slotting tool, which passes into the bore and cuts the keyway in a series of strokes. This machine may also be hand-driven or actuated by a belt or rope wheel.

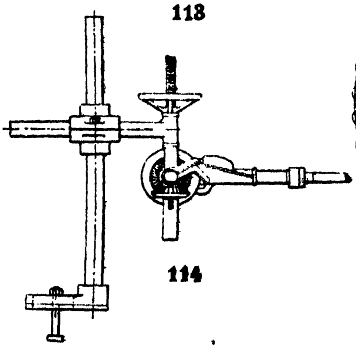
Light Tools. We now arrive at a large group of machines which have developed greatly in recent years, those operated electrically or pneumatically. Both these sources of power are admirably suited to the needs of portable tools, and they are applied in a variety of ways to drive with a rotary or a reciprocating motion. The obvious advantages are that the power can be conveyed to the tools in a very flexible manner, to accommodate any movements or positions, and without such encumbrance as would be found if ropes or belts were used. On outdoor work especially these rope or belt drives are most awkward to produce, because of the difficulty of finding a location from which to drive off, whereas in a shop an overhead countershaft may be attached to the ceiling joists. On the other hand, an electric cable, or a pneumatic hose is simply laid along the ground and carried over obstacles without trouble or regard being paid to angles or to passing around corners.

Before the advent of the electric and pneumatic motors, a certain amount of portable work was effected with steam and hydraulic engines, chiefly for drilling, to save time over ratcheting with a

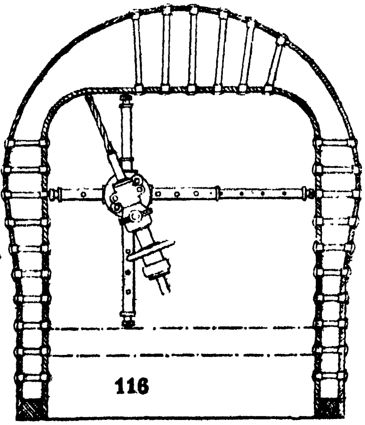


112

113



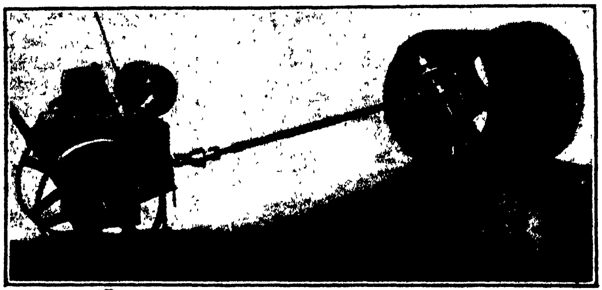
114



116

112-114. Portable electric drill **116.** Portable drill inside firebox

"John Bull," or drilling pillar, and a ratchet brace [see 108, page 835], which is a slow method, although convenient where no power is available, as are also the hand-driven drills operated through a handle and bevel gears driving the drill spindle. The steam was, however, an inconvenient source of power, due to the condensation which occurs in the long pipes, and the trouble caused by leakages. Hydraulic power also suffers limitations. Electricity gives no trouble, nor does air, if the pipes are not leaky. The source of power—the dynamo, or the air-compressor—may be placed in any convenient location; in a large works there will be many scores of portable machines all drawing their energy from a central source. Ship and bridge-building yards especially favour the use of these agents, because so much of the work has to be done upon partly erected structures.

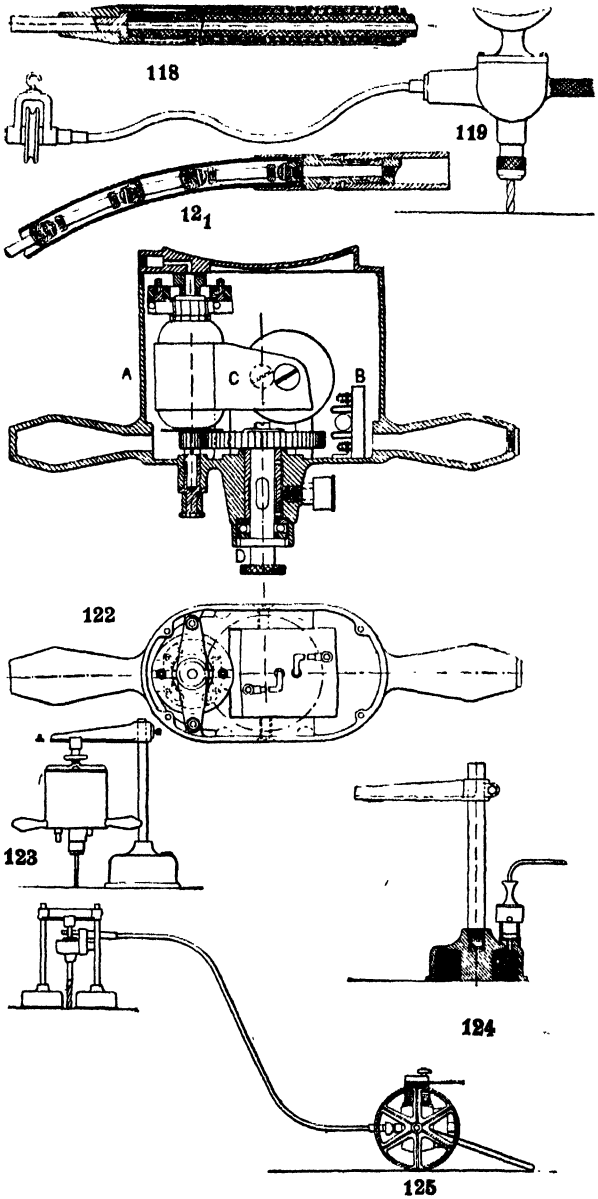


115. PORTABLE ELECTRIC DRILLING OUTFIT

There are two principal methods of driving the light portable tools: the actuating motor is either built into the body of the machine, or it is situated a little distance off, and the movement is transmitted to the tool through the medium of ropes or cords, or by flexible shafts, or both combined. The reason for the adoption of one or the other device is chiefly one of weight; it would be inconvenient and troublesome to keep shifting a heavy motor about over the work, especially if the latter should be placed in difficult situations, and the time occupied in setting and adjusting would be out of all reason. But if the class of operation is so light that the motor and the machine parts can be moved about easily by one or two men, then the flexible shaft can be dispensed with. As we shall see later in this article, some of the lightest tools can be handled with the greatest ease by one man, yet their capacity far exceeds that of the older hand-driven tools. The commonest class of operation done by these light portable tools is drilling, as it was also the first effected by their aid when the early attempts to oust handwork were made. The scope of the tools has, however, greatly extended, and many operations that were once deemed outside the range of power-driven machines are carried out extensively nowadays.

117. BORING DYNAMO HOUSING WITH PORTABLE MACHINE

Electrically Driven Drill. We shall consider first a class of drilling machine driven from an ordinary shaft, which, nevertheless, allows a great degree of flexibility in the position of the drill. The machine, by Campbell & Isherwood, Bootle, is shown in 112 and 113, the first being a sectional elevation through the motor and the drill, and the second an external elevation of the motor and its stand. The electric motor, A, is enclosed and a pinion on its shaft drives a spur wheel on a sleeve in bearings above the motor. The sleeve rotates the shaft B, which is free to slide endwise through the sleeve, though driven positively by it at any position through a key fitting in a spline extending down the shaft. The motor, and its frame, including the gears and shaft, may pivot in a vertical direction through the medium of trunnion bearings [see 113]. These bearings are mounted upon a truck, C, by a circular facing and central pin, which permits the motor and trunnion bearings to turn freely into any position. The universal movements thus obtainable allow the operator to bring the drilling head, D, into any location he may desire, up or down, or sideways. The base, C, is fitted with a couple of trolley wheels, and two handles, as seen, so that it may be wheeled about, and brought into position. The plain feet at the opposite end to the trolley wheels prevent motion when the machine is standing. There is an eyebolt screwed into the top of the frame, by which the whole affair may be slung up in the air, if more convenient than the ground position. The shaft, B, is coupled to the drill head shaft with a taper and union nut, and the motion is transmitted thence to the drill spindle through bevel gears. The spindle can be swivelled to any angle, and the feed is imparted by the hand wheel and screw fitting inside the drill sleeve, the [illegible] of the screw having a point centre which thrusts against any convenient projection, or against an arm attached to a pillar, or "John Bull," provided with a foot to bolt to the work [114]. A small switch attached to the side of the head, D, enables the operator to start or stop the motor, A, at will, the flexible connecting wires being laid between the two. These machines are made in three sizes, with capacities for holes ranging from 1 in. to 3 in. diameter, the drill speeds varying from 180 down to 60 revolutions per minute. The motor being a series-wound type, the speed of the drill is proportionate to the duty imposed. In a different design, three-speed gears are included with the



PORTABLE MACHINE TOOLS

118 to 121. Flexible shafts for transmitting power **122.** Electric drill **123–125.** Magnetic drilling pillars

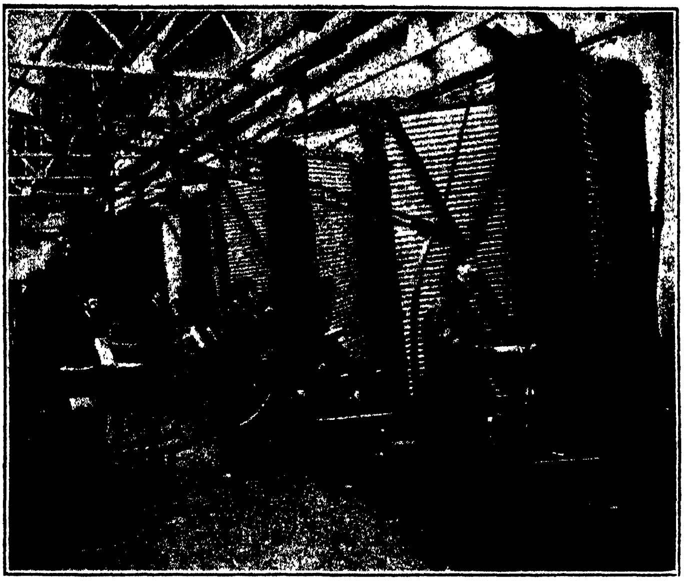
motor frame, to afford considerable variations in speeds, for tapping, and other operations besides drilling.

Universal Shaft Drive. In a different class of drive, which is largely adopted, flexibility of connection is obtained by making the shaft with universal joints, having double-pivoted or ball fastenings, which allow the parts of the shaft to assume angular positions. This being the case, there is no need to tilt the driving motor. The differences in distance between the motor and the drill are provided for by fitting one part of the shaft within the other, and making them drive by a sliding key, constituting a telescopic shaft. Figure **115** is a good example of this mode of driving, from the practice of Emil Capitaine & Co., Frankfort-on-Main; the portable motor, seen to the left, mounted on wheels, receives its current from a flexible cable, which is wound around the drum on the top, at the front. A drive is taken from the motor shaft to a socket on the front, into which the end of the universal shaft is fastened. The universal joint at this location drives the telescopic part of the shaft to another joint, which rotates the drill spindle through gears; the spindle is held in a frame that may be secured to the work, in this case a boiler flue, by adjusting screws.

Arrangements are made for giving different speeds by having a set of gears inside the motor frame driving to three different sockets, at various speeds, the end of the universal shaft being inserted in either, as desired. Or if two drills happen to be wanted in use adjacent to each other, a couple of shafts may lead from the sockets and diverge to their respective heads. A device which still further increases the possibilities of drilling is the *distributor*, a small stand having several connections leading out of it for driving universal shafts, the power being put in by another shaft from a motor situated a little way off. When the distributor is laid down on the floor, it operates four or more drills surrounding it, and occupies far less space than that required by the necessary number of separate motors.

A somewhat similar class of rig to that shown in **115** is illustrated in **116**, also a Capitaine device. The drilling head is held to a casting from which four tubes radiate, and carry rods, which are slid into any position and locked with small pins. Screws on the end of the rods tighten the affair inside the work, a fire-box in the example given. The drill spindle, driven from a universal shaft extending into the box, is then turned into various positions to drill the stay holes. The dotted stretcher bar seen near the bottom is necessary only when the drill is pointing vertically.

Boring and Drilling Rig. Another application of the Capitaine machine is that in **117**, which shows a boring rig in operation on the face of a large dynamo housing in the shops of the Allgemeine Electricitäts-Gesellschaft, at Berlin. The drill head is driven, in this case, by a worm gear, enclosed, from a universal telescopic shaft coming up from the portable motor seen on the floor, and is held in a large slotted base piece bolted to the face of the work. As the base and the drill head are too heavy to lift about, a stirrup is attached, and suspended from the overhead crane. The man is in the act of turning the hand wheel that gives the feed to the tool. A boring bar, supported between two bearings, may also be driven in this manner, with a universal shaft. There is a different method of driving used when the electric motor is not possible: the universal shaft is worked from a suspended pulley, connected with a hanging rod to a pulley in the ceiling, which allows a good deal of accommodation to follow the varying positions of the drill. The device is, of course, more awkward and cumbersome than the motor drive, and is liable to get in the way of tall work.



120. FLEXIBLE SHAFTS DRIVING TUBE EXPANDERS

The Flexible Shaft Drive. The *flexible* shaft differs from the universal telescopic in being able to bend, due to its peculiar construction. With one end attached to and driven from the motor or other source of power, the free end may be turned into any position which the tool demands. The shaft may be bent round a corner, where one of the straight shafts previously discussed could not be brought into action. The first flexible shaft was the Stow, a type still employed very largely; it consists of a number of steel wires wound in right and left hand directions, and fitting within each other to form a sufficiently strong driving medium; the outermost layer runs inside a flexible tube formed of coiled wires of square section, and this again is encased in a leather covering. A lubricant is applied to the running portion, either lard oil, or tallow, but not a mineral oil, to enable it to run freely. The action of the wires will be readily understood by taking hold of a spiral spring by its ends, bending it to an angle, and revolving one end, when it will be found that the motion is transmitted around the bend. The reason for multiplying the coils is that a single one would not be able to stand the strain unless it was of excessive thickness, and this would interfere seriously with the flexibility. The ends of the core are attached to a short, plain end, which forms a means of attaching the driving and the driven portions.

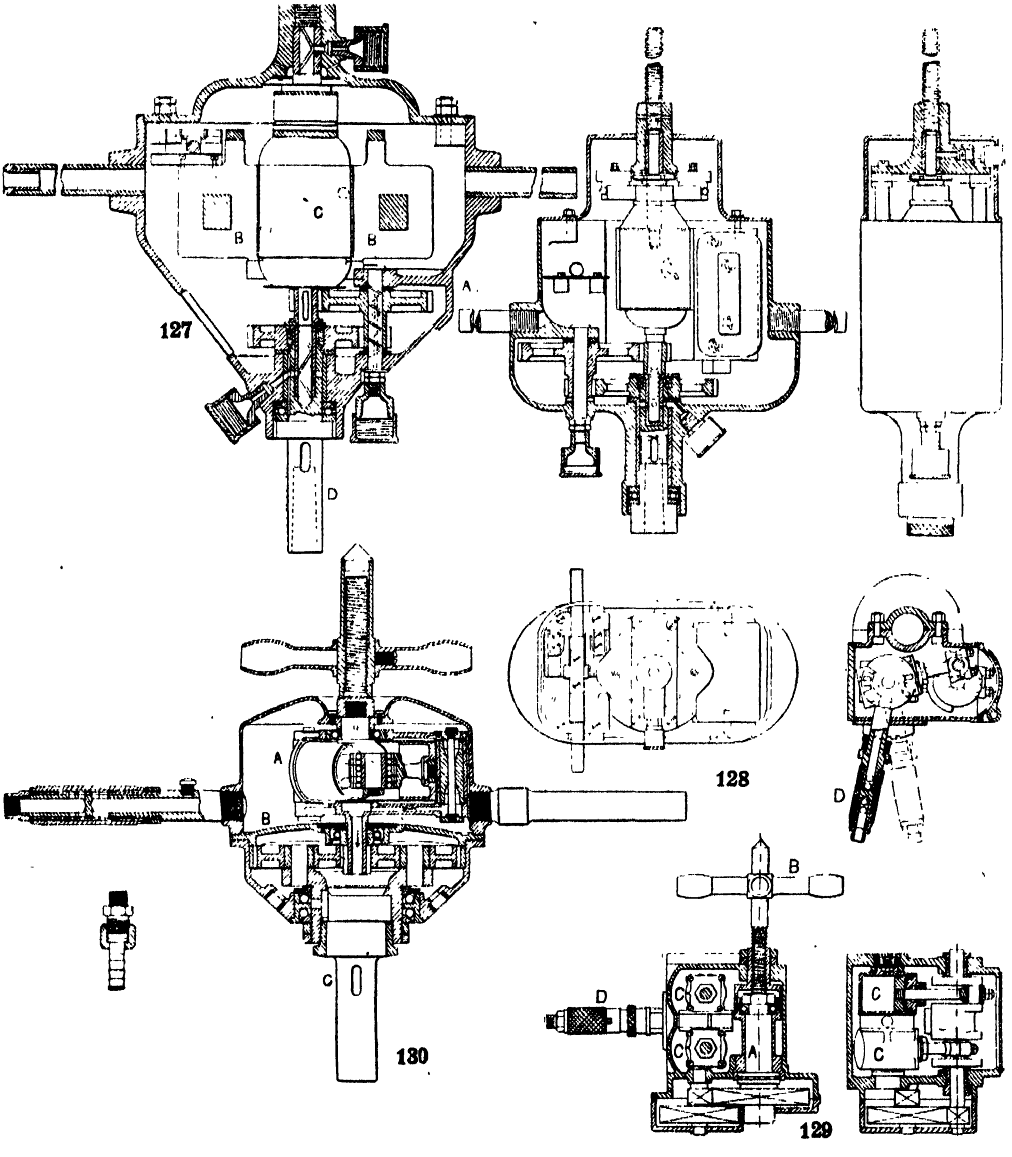
Figure 118 shows a section of the end of a shaft by Kramos, Ltd., Bath, embodying the central core of wires (indicated by cross-hatching), the outer bearing tube, and the leather casing. The end of the core is fitted to a short piece of shaft projecting through a bearing, the free portion of shaft being available for putting on various styles of fittings. In 119 the shaft end has a rope pulley, with a hook by which it is suspended, while the pulley is driven from a cord actuated from an overhead drive, or from a motor. The other end of the shaft connects to a breast drill, driving the spindle through intermediary bevel gears inside the casing.

126. ELECTRIC DRILL WITH MAGNETIC POSTS

An interesting example of the use of flexible shafts is illustrated by 120, the view being taken in the works of Messrs. Yarrow & Co., Ltd., at Poplar, where the system has been in use for many years. The operation is that of expanding the tubes in water-tube boiler sections, the expanders, of a similar character to those described on page 3104, being rotated from the shafts through bevel gears, similarly to drills. In the foreground of 120 the shaft is seen to be operated from a rope and pulley, the rope being driven from a countershaft. The second shaft is deriving its power from a portable electric motor (very much like that in 112 and 113).

It is usually advisable to connect the driving end of a flexible shaft with a universal joint, to prevent risk of too sharp a bend being made, which would put an excessive strain upon the core on the end portion.

The Coates flexible shaft, instead of possessing a central core of wires, has a number of short sockets and studs fitting into each other with ball ends and transverse studs, so that although the drive is positive, angular relations may occur between the units. The core revolves within a spiral casing, which is surrounded with a protective covering; ample lubrication is essential. The Wicksteed shaft, shown in section in 121, which represents one end and a few joints, is built up of connecting rods with universal joints screwed on the ends to give the required flexibility; the outer casing is a flexible metallic tube which holds the lubricating oil for the joints to run in. Ball races



127 and **128.** Electric drills **129.** Two-cylinder pneumatic drill **130.** Three-cylinder pneumatic drill

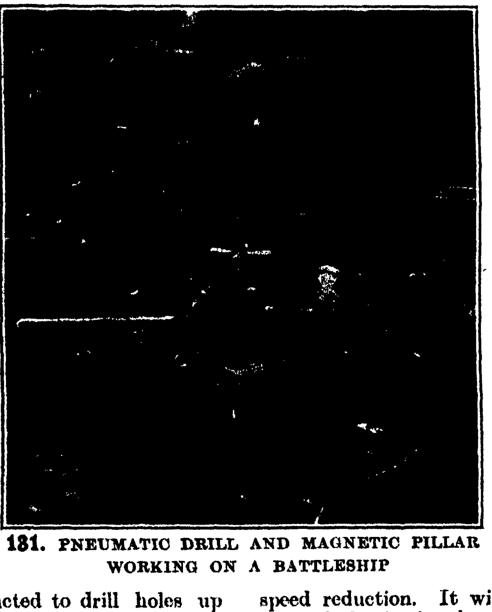
are fitted to the peripheries of the universal joints to reduce the friction and wear on the inside of the casing to a minimum. The end of the shaft has a positive or friction clutch by which connection is effected to the tools. The dimensions range from an outside diameter of casing of $\frac{3}{4}$ in. up to $2\frac{1}{4}$ in., transmitting powers from $\frac{1}{8}$-h.p. up to 3-h.p. They can be made in any length required, as friction is small. Messrs. C. Wicksteed & Co., Kettering, the makers of this shaft, provide a portable electric motor, carried on a trolley, upon which the motor may be revolved. The shaft receives its motion from a second shaft driven at a suitable rate from the motor through friction safety gear.

In addition to the operations of drilling and expanding mentioned, various other tools may be conveniently driven from these flexible shafts, such as taps and reamers, wood-boring tools, and grinding and polishing wheels. The latter is a very useful application for grinding and polishing work which could not be conveniently done on a fixed grinder. The operator simply holds the wheel by means of two projecting handles on the bearings, and moves it about over the work, to smooth down the inequalities, and produce a good surface. The flexible shaft sticking out from one handle does not interfere with the free movements of the wheel to and fro, or into awkward corners.

Direct Driving. The direct-driven tools—that is, those which have the motor built into the body—are very numerous; they possess the great advantage that no moving shafts or ropes are in the way of the work or the attendant, the only connections being cables or pipes, which can be laid along in any manner that happens to be convenient. The direct-driving method also lessens complication, and there is only the drill or other machine to be carried about, instead of a separate portable motor, with its connecting ropes or shafts.

Electric Drills. The electric drills are either of *hand* or *breast* type, or used with a *pillar*, which supports the machine and takes the thrust of the cutting. The pillar, in addition to holding the machine ready, keeps it at the correct angle to the surface of the work; when gripped in the hands alone, it is not easy to be sure that the drill points quite squarely, though the accuracy or otherwise may be judged near enough by the eye for ordinary work. The hand drills must be provided with projecting handles by which they are controlled easily; **122** gives two views of an electric hand or breast drill (Kramos, Ltd.) of small size, weighing about 15½ lb. and drilling holes up to ⅝ in. It consumes 1·2 amperes at 110 volts, and is worked from a lamp-holder socket, as used for incandescent lighting. The case, A, is cast in aluminium for lightness, together with the two hollow handles, the right-hand one serving as a passage through which the flexible wires are led to the motor, first connecting to a switch, B, operated by the attendant from the outside, to start and stop the drill instantly. The motor, C, is attached with screws inside the case, which fits the outsides of the pole-pieces exactly, as may be seen in the plan view. The armature revolves with its shaft in a bushed lower bearing and an upper stretcher bearing, the latter being necessarily screwed on after the armature has been dropped into place.

As sufficient power would not be afforded by the rotation of the armature, a gain is effected by reduction gears, comprising a pinion on the armature shaft, driving a large spur wheel on the drill spindle, so that the latter revolves at a slower rate. The drills are held in a tapered hole in the spindle; the latter runs in a gun-metal bush, lubricated with a Stauffer type lubricator, and the thrust of drilling is taken against a ring of balls, which greatly reduces the friction. The curved plate at the top end of the case is shaped thus to fit the operator's chest as he leans over and presses the tool down, while grasping the two handles. This plate is screwed on to the case; in the plan view it is shown removed. Another pattern of this machine is constructed to drill holes up to ½ in. diameter. The speeds are arranged to suit high-speed steel drills.



131. PNEUMATIC DRILL AND MAGNETIC PILLAR WORKING ON A BATTLESHIP

If required for some kinds of drilling, the curved breastplate may be replaced by a plate fitted with a feeding screw, to press against any convenient part of the job, or to be suspended from a pillar and arm [**123**]. The arm is of tee-section, and holds a hooked extension of the drill screw, so that the machine hangs steadily when not at work, instead of falling down like the ordinary types with a point centre thrusting against the underside of the arm.

Magnetic Pillar. The pillar shown in this illustration is not of the usual style, secured with bolts to the work, but is of the *electro-magnetic* type, which clings to the iron or steel work by the action of a magnet base. The advantages of this device are obvious, for it not only saves a large amount of time otherwise occupied by bolting down the foot, but enables the latter to be secured to broad, flat faces where bolts or clamps could not be fixed, unless of unusual or very long types. The magnetic base, therefore, fills a particularly useful position in ship and girder yards, where plates of broad area are common. Figure **124** (Kramos, Ltd.) gives a sectional view of the base, which is hollowed out to receive the energising solenoid, the wires being represented by cross-hatching. The current is led through the flexible wires to a plug which is dropped into the holder on the top of the foot, which thus becomes strongly magnetised, and clings firmly to the work. It is released immediately the plug is removed from the holder. The arm on the round pillar may, of course, be moved around, or up and down into any desired position, and clamped by the set-screw which squeezes in the split lug.

Two pillars may be employed for heavy service, as in **125**, where the drill is suspended from an arm spanning between them; the drill in this example is driven from a flexible shaft, operated by a portable motor, of the class mentioned previously. A photograph showing the application of an electric drill with duplex magnetic pillars, by the Consolidated Pneumatic Tool Co., Ltd., London, is given in **126**, the drill being put through a girder of a bridge, while the magnetic feet adhere to the vertical face of the plate. The pillars are made of tubes, for the sake of lightness, and a number of holes are drilled to receive pins, which take the thrust of the spanning arm against which the drill presses.

Heavy Electric Drill. A heavier electric Kramos drill, which is suitable for holes up to 1¼ in. and weighs about 60 lb., is shown in section by **127**. The aluminium casing, A, of approximately triangular form, holds the heavy pole-pieces, B B, between which the armature, C, rotates. The drill spindle, D, is driven through a set of back gears, affording a considerable power gain, with corresponding speed reduction. It will be noted that the armature shaft is in the same plane as the drill spindle, and the bottom end of the former runs in a hole in the latter without interfering with the last spur gear attached to the outside of the spindle. The details of the bearings, with a ball thrust to the spindle, and the lubricating devices may be seen clearly. The current is taken through the left-hand handle, formed of pipe screwed into the casing, to the starting switch. The handles serve a double purpose—that of providing a means of lifting the tool about, and also of preventing

135 and **136.** Pneumatic chipping hammers

the case from rotating during use, because they catch against the drilling pillar. The thrust of the drill is produced by an ordinary hand wheel and screw device, let into the top of the case, though not shown. In some kinds of work, such as counter-sinking, which can be drilled with the machine standing vertically, the pillar may be dispensed with and the tool simply steadied by the hands, while its weight is sufficient to give the drill its feed.

137. PNEUMATIC CHIPPING HAMMER FETTLING CASTINGS

Figure 128 shows another drill by Messrs. Kramos, which, though of different shape, embodies somewhat similar construction and mode of driving with gears. It contains many interesting details that may be studied. The feed screw is shown let into the top. The switch is operated by pushing one or other of the plungers seen in the plan view, the effect being to slide the contact piece in between the two springy pole strips, or away from them. A safety fuse is provided with these drills, which blows out should an excessive amount of current pass, and so saves the motor from damage. Owing to the high speed of the working parts efficient lubrication is essential, and particular attention is paid to this point.

Pneumatic Tools. The pneumatic tools constitute a large proportion of the light classes employed in works; they come into rivalry with the electric types to a certain extent, while in some cases they do work which electricity is unable to effect—that is, those which employ hammering, or reciprocating movements. One reason for the frequent adoption of electric tools is that so many firms have current laid on throughout their works, which is readily applicable to driving portable tools, and a pneumatic plant may not be installed. When, however, the latter is put in, full advantage is taken, and tools of widely varied character are brought into service. The power is derived from air passed from an air compressor, at pressures which are varied to suit the work, but usually at 80 lb. per square inch; a receiver stores a quantity as a reserve for the tools to draw from. Portable compressing plants are used on outdoor work, where it may be desirable to shift the compressor, etc., about to different situations. Hose pipes lead from the receiver to the tools, the armoured type of hose, protected with coiled wire, being preferable on account of the rough usage and dragging about which it has to endure. A coupling unites the hose to the pneumatic tool, and means of shutting off the supply of air are provided, as we shall see later.

138. PNEUMATIC CAULKING TOOL IN OPERATION

Pneumatic Drill. The production of a rotary motion by compressed air is effected in the majority of cases by cylinders and reciprocating pistons, like those of steam engines. Figure 129 gives three views of a reversible drill (made by the Howard Pneumatic Engineering Co., Ltd., Eastbourne), which is of rather simple construction. The casing, cast in aluminium, holds the drill spindle, A, inside a sleeve, from which the thrust is taken by ball races and transmitted direct to the feed screw, B. The rotation of the spindle is produced from a pair of little oscillating cylinders, C C, which are mounted on trunnions, and which, as they oscillate, cover and uncover the air passages in a block lying between them, so admitting and exhausting air alternately to the opposite sides of the pistons. The handle, D, serves to steady the machine, and also to turn on the air, by partly twisting the knurled outer sleeve, which lets the air pass through holes and so from the supply pipe screwed on the handle end, to the cylinders. This handle is used as well to reverse the direction of motion of the engines. It is screwed into the valve disc between the cylinders, and has a spring collar on its body which engages in slots cut in a quadrant outside the casing. By swivelling D around to the position indicated by the dotted lines in the plan the relations of the inlet and exhaust passages are altered, and so the engine runs backwards, a useful provision for tapping and tube expanding.

The piston rods of the two cylinders drive to crankpins at right angles on a balanced crankshaft, on the end of which there is a spur pinion meshing with a wheel which drives another pinion engaging with a large spur wheel on the drill spindle. The crankshaft rotates from ten to fourteen times as fast as the spindle. By taking off the cover at the bottom, removing the pinion on the crankshaft, and its companion wheel, and substituting others of different ratios, varying rates of speed may be obtained to suit the operations done. A reducing gear is also fitted as an extra to the front of the drills, by which a slow and very powerful motion is obtained for heavy tapping. Another useful attachment is the extension gear, consisting of a small auxiliary spindle with its feed screw standing out from the casing of the machine in a manner that enables holes to be drilled in very close situations, such as in corners, or close up to plates, which would prevent the main spindle from being brought into action, on account of the bulkiness of the casing.

The Howard Company have a little machine designed for drilling metal and wood with drills and bits of small diameter, which drives by means of a fan wheel with vanes at a very high speed.

The Boyer drill [130] (Consolidated Pneumatic Tool Co., Ltd.) is a rather unique design, possessing three cylinders, A, which revolve around a common pin-crank that is fixed into the top of the cover. A diaphragm, B, separates an upper chamber containing the cylinders from a lower one holding the toothed driving gears. Air is admitted to the top chamber through the throttle handle on the left, and causes the single-acting cylinders, through the medium of their pistons, to revolve a disc ending in a hollow shaft that passes centrally through the diaphragm, B, with a leather washer surrounding the hole. No air can therefore get out of the upper chamber, except through the cylinders and along an exhaust passage communicating with this hollow shaft, whence it escapes through two holes on the sloping undersides of the case. A small pinion is fastened on the end of the hollow shaft, and engages with two spur gears meshing with an internal ring of teeth inside the case. Each wheel fits on a pin forming part of a sleeve or socket holding the drill spindle, C, and as the wheels travel rapidly round the ring of teeth they carry the sleeve with them, and so rotate the drill. Ball bearings are fitted to relieve the friction A drawing of a four-cylinder reversible drill by the same firm was given on page 1803, to which reference may be made.

In **131** we have an example showing the application of a pneumatic drill, in conjunction with a magnetic stand, drilling the deck-plates of a battleship. This illustration is from the practice of the Pneumatic Engineering Appliances Co., Ltd., London, the drill being one of their Thor types with four cylinders.

Pneumatic Grinders. Grinding machines, driven pneumatically, are coming into use to a considerable extent for finishing and trimming surfaces which cannot be handled on ordinary grinders in the shops. Figure **132** shows the Whitelaw grinder (Consolidated Pneumatic Tool Co., Ltd.). The frame, of flattened form, with rounding ends, carries two oscillating cylinders on trunnions, with a valve set between the two. The piston rods drive the pins of the crank, on the end of which is mounted a grinding wheel. The two knurled handles seen are for holding the machine to its work, the lowermost one taking the hose, and shutting off the air or turning it on, with a mechanism similar to types described before.

Figure **133** illustrates another Whitelaw grinder by the same firm, for a 10-in. wheel, which has the two handles placed in a better position for even control; they are round knurled sleeves set in extensions of the frame, one of them being a valve. Two oscillating cylinders on each side of the wheel drive it (one cylinder only is seen in section). An eyelet in the top of the frame is useful for suspending the latter over the work while the attendant guides it about. If a very flat surface has to be ground, the wheel may be controlled by fitting guide strips to surround

everywhere, and move in a true plane. Some of the largest machines are designed for grinding armour-plate after it has been put into place.

Reciprocating Pneumatic Tools. The rotative types of pneumatic motors all have their rivals in the electric motors, but there is another field in which they hold their own—in the production of reciprocating motion, for striking blows, an operation that cannot be effected by electricity except in a very roundabout and clumsy manner. The mode of action is to drive a sliding piston alternately to and fro, causing it to strike an extension of the tool, and so deliver a rapid series of sharp blows, from 600 to 2,000 per minute. The operator holds the tool and keeps it up to its work, air being led from the supply through a flexible hose.

Hammers for chipping, caulking, and riveting do not differ from each other in the essential action, but as the last-named operation demands very heavy blows in order to close up the rivet tails quickly, what is termed a *long-stroke* hammer is used, constructed with a much longer barrel than the chipping hammers, in order to give the piston a longer stroke. The air pressure is also usually greater, averaging 100 lb. per square inch.

Pneumatic Hammers. A sectional drawing of long-stroke hammer has been given on page 1803, of the Boyer type. In **134** the Tierney riveting hammer (the Globe Pneumatic Engineering Co., Ltd., London) is illustrated in outside and sectional views. The air is led in through the screwed hole at the bottom of the handle A, and is admitted at will by the operator when he clasps the lever B, which has the effect of opening the spring-closed valve and passing the air up the passage C, from which it gets through holes and past the valve (shown black) behind the piston D, driving the latter forward until the hole H is uncovered, which admits air at full pressure and drives D with great force against snap E. The automatic action of the valve (shown black for clearness) then shuts off the air behind, and admits a supply in front of the piston, through the long passage F and hole G, driving D backwards in readiness for another blow. The exhaust takes place through H.

A Tierney chipping hammer of shorter stroke is illustrated in **135** in external and sectional elevations, with a chisel in position, and also shown separately. The shank fits by a part round and part octagonal portion, to prevent its rotating in the bushing that is fixed in the nose of the tool. The action of the hammer is similar to that in **134**, but a modification is made in the position of the air-holes on the underside, because of the greater length of the piston (seen separately).

A duplex-valve hammer made by the Pneumatic Engineering Appliances Co., Ltd., London, shown in **136**, is noticeable on account of the double valves, which give a better action to the tool at high speeds. The air is taken in by a pipe screwed into the hole at the bottom of A, and is controlled by the thumb lever B, which operates the spring valve inside C, letting the air rush against the ends of the circular valves DD, and force them apart, so that they uncover small ports communicating with the

covered up two holes connected with pass and J, and live air is admitted through the K, and around the recess on the piston into L, which cause the air to get behind the valves and drive them inwards, allowing the air behind the piston to exhaust through a hole in the cylinder end and out through other holes in the handle to the atmosphere. At the same time air is passed through small holes in the valves D, along a passage, and in front of the piston, where the escape drives the piston backwards.

Figure **137** shows one of these hammers in operation, the work being that of fettling castings; **138** illustrates the mode of application of a caulking tool on boiler seams, the example being a tool by R. G. Ross & Son, Glasgow. Beading, or hammering over the ends of boiler tubes, is another operation effected by pneumatic tools. There are also pneumatic sand rammers for moulders.

LOCKING-UP THE PAGES

Placing the Pages in Chases and Formes. Schemes of Imposition. Sizes of Paper. Arranging Margins. The Work of the Reader

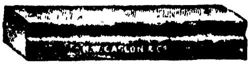
Group 19
PRINTING
4

Continued from page 523

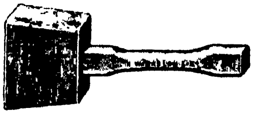
By W. S. MURPHY

the type has been made up into pages and tied ever so carefully, it is not by any means ready for printing. The machine man would not take it off our hands in that condition. Slide the type off your galley on to the large table with the smooth iron top, designated the stone. The pages lie in a row—one, two, three, four. Supposing the pages are to be printed one by one, and on one side of the paper only, the job is easy.

Placing the Pages into the Chase. You get an iron frame called a *chase*, from the chase-rack, and lay it over page 1. If possible, the type should be protected from the iron side of the chase, and the chase is therefore bigger than the page. A piece of metal or wooden furniture exactly the same length as the breadth of the page is laid between the top and the chase, and a similar piece a little longer than the page is laid along the side. Now open one of the drawers hung under the table, and find a store of wooden wedges, of many sizes, straight on the one side and slanted on the other. These are *sidesticks* and *footsticks*. Select one the length of the bottom of the page, and another for the side, and set them close to the type, making sure that they will cover the whole of the type, and yet be free of each other. Take the cord off the page, and press the sticks close on it. Open another of the table drawers, and there are little wedges of wood called *quoins* varying in breadth from a mere splinter to 1½ in.



19. PLANER



20. MALLET

21. SHOOTING-STICK

Planer, Mallet, and Shooting-stick. In the same drawer lie a heavy, flat slab of wood, a short-handled wooden mallet, and a round tool with wedge point—these are *planer* [**19**], *mallet* [**20**], and *shooting-stick* [**21**]. Wedge in quoins of suitable size between the footstick and sidestick, and the inside of the iron chase, fixing them with finger and thumb. Take the planer in your left hand and let it rest lightly and evenly on the face of the page, gently tapping it down with the mallet in your right. This makes the type level. With shooting-stick and mallet drive home the quoins, plane the type level again, and the page is locked up.

A few fancy books and ornamental pamphlets are printed page by page, but the mass of printing is done quite differently. From the foregoing, however, the student will learn the rudiments of *locking-up*. The page of type, if it has been properly set and firmly locked up, has become a rigid solid, capable of standing the pressure and pull of the printing press or machine.

As we have said, books are not printed page by page; sometimes 128 pages are printed at one time on a single sheet. Here we come to one of the most difficult lessons the young printer has to learn.

Sizes of Sheets for Printing. On opening a book, the first thing the reader observes is the fact that page 2 is printed on the back of page 1, page 4 on the back of page 3, and so on. Nothing seems easier than just to print one side of a sheet with the even number pages, and another with the odd number pages. This would be a feasible plan if all the leaves of books were cut separate, and then bound together leaf by leaf. But books are not made that way. Four at least, should be on one sheet. Fold a sheet and you have two leaves, or folio; folded again' it is four leaves, or quarto; folded again, eight leaves, or octavo. A sheet of folio has four pages, a sheet of quarto eight, octavo sixteen, and so on. Most of the old books are folios, because the early printing presses could hold no more than two pages at a time. Shakespeare's plays, for example, were printed folio. The beginner is apt to take those terms as denoting sizes, but that is an error. Folio is simply the half of any size of sheet, whether small post or double demy; quarto is the fourth, octavo the eighth, 16mo the sixteenth, and up to any fraction. We give on this page two tables, the one showing the sizes of papers commonly used, and the other the proportions of the divisions expressed in inches.

STANDARD SIZES OF WRITING AND PRINTING PAPERS.

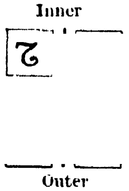
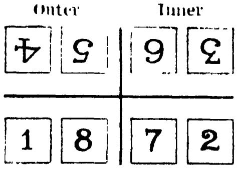
Placing the Pages. *Imposition* means the placing of things in a definite position, or putting one thing in the place of another; both meanings describe the printer's method of placing his pages. For, it is to be noted, the sheet has to be printed on both sides, and the pages are made up in two divisions, the one called the outer forme, the other the inner. The pages of the outer forme are put in position, and the pages of the inner forme take their places.



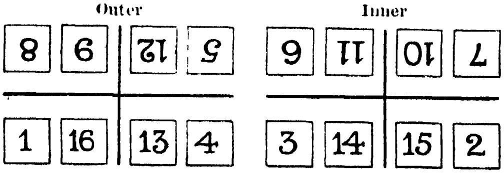
22. SHEET FOLIO

We will begin by imposing the formes of folio [22]. Fold a sheet of paper, and number the pages 1, 2, 3, 4; 1 and 4 are on the same side of the sheet; 1 always begins the outer forme; therefore, 1 and 4 are to be placed together, and make up this forme. Page 1, or the lowest number in every outer forme, stands at the left-hand corner of the scheme. With exceptions to be specially noted, the highest number of the sheet stands next to page 1. In this case it is page 4. Pages 2 and 3 stand together, of course, but it is not enough to say so. The inner forme is the reverse of the outer, and instead of 1 and 4, the order runs 3 and 2.

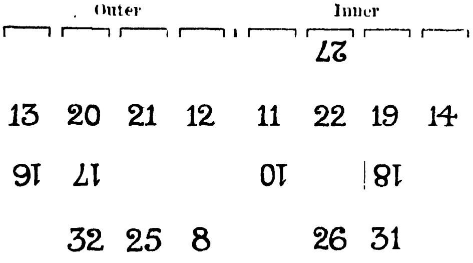


23. SHEET QUARTO

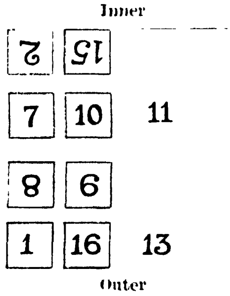
How to Impose the Folio. A good way of finding out schemes of imposition of a complex kind is to number the pages on the sheet, and lay it on the imposing table. The sheet is numbered on both sides; the numbers on the under side of the sheet show the position of the corresponding pages. Our folio sheet affords a simple example. Laid on its back, its pages 1 and 4 lie next the table; turned over sideways, page 3 lies on the place of page 1, and 2 on 4. No matter how complex the problem, this plan always yields accurate results. Another method adopted by beginners who have not mastered the principles of imposition is to take a sheet double the size of that which is being imposed, or twice the number of leaves, and write the numbers on alternate pages, except at the centre, making all the numbers appear on one side of the paper. Turn the figures down on the table; the sheet presents a perfect picture of both the outer and the inner formes. Lift it up again, fold it across, and note how 1 falls on 2, 3 on 4, 5 on 6, 7 on 8.



24. SHEET OCTAVO



25. SHEET SIXTEENS



26. HALF-SHEET SIXTEENS

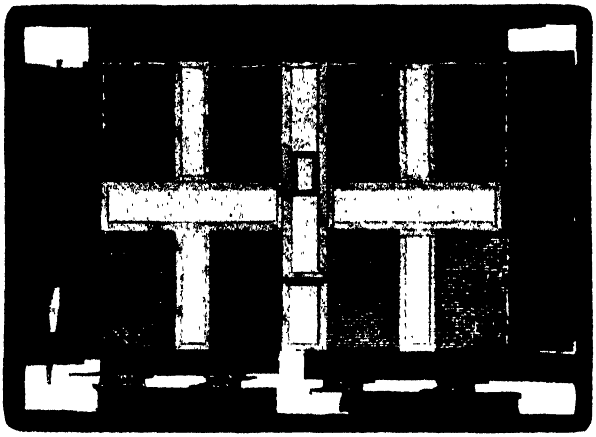
The quarto sheet offers no difficulty. Have both formes in your eye, as shown in 23. The outer circle, taking both formes, is 1, 2, 3, 4, and the inner is 8, 7, 6, 5.

Octavo seems to begin complexity in imposition; but if it is kept in mind that this sheet is four times folio, and the same method applied, the scheme will build itself by natural sequence [**24**], and similarly with the larger sheets [**25 and 26**].

Irregular Sizes. The above form the ground-work of imposition. Irregular sizes of sheets, such as 12mo, 18mo, and 24mo, can readily be mastered by application of the methods described and practical experience. To a very great extent, those odd schemes were rendered necessary by the conservatism of the paper-makers, who kept to the old sizes and forms of paper, and the progressive spirit in the printing trade. That opposition has completely disappeared. Paper-makers supply sheets by the roll, measured by the yard, of any breadth desired. The old sizes are rapidly going out of use; off-cuts that make waste of good paper are becoming needless, and intricate foldings, perplexing to the bookbinder, ceasing to trouble.

Arranging for Margins. Having laid our pages our duty is not done. The outer forme of this sheet of octavo has to be locked up. On the chase-rack we find a chase of the proper size, with cross-bars. These are wrought-iron bars fixed in the chase, dividing the interior into four. The pages lie within the divisions, two and two, the heads touching the longer cross-bar. Every page has a fore-edge or front margin, a tail or bottom margin, and a head and a back margin. Provision for the four margins has to be made in due measure. Say that the size of paper gives an inch of margin all round the page. If an equal margin is to be made all round, twelve ems of pica between the sides and heads of the pages would answer. But imposing is not so simple as that. The bookbinder has to be considered, and artistic taste has also something to ask. The outer margin of a page should be wider than the back, and in binding a book the fore-side is often cut. The bottom of the page, being solid, demands a larger margin than the head, which shows white paper between the solid type and the page number, heading, etc. The rule-of-thumb method is to measure with the paper. Having placed the pages in position, fold the paper to page size. Lay the paper across page 1, and rest it on the edge of page 16. Let the paper overlap the outside of page 1 by as much as you wish the fore-end margin to exceed the back margin, and put furniture into the gap between the two. Open the paper, and you will find, by laying it across both pages together, that the margin on both sides is equal. The space between pages 16 and 13 represents two fore-end margins. To find out this, lay the paper, which is now quarto, against the side of page 13, extending across pages 16 and 1, and make the gap between pages 13 and 16 so that the paper just runs along the outer edge of page 1. These measurements afford the gauges for the rest of the forme. By a similar method, the space between the heads is determined. As we have hinted, however, the more sensible and quicker method is to divide up the margins into a given number of points, or pica ems, and proceed to lay them in, without further trouble.

How to Avoid Mistakes. In the hurry of making up pages and formes, a number of mistakes occur. One page may be a line short, or another a line too long; the furniture between the pages may be of wrong lengths, or miscounted in breadth. To detect all such errors before locking up, the compositor should be provided with a points gauge or a measuring scale. Either of these tools helps in the making up, too. Here is another advantage of the points system of type measurement. When the compositor knows that 36 lines of long primer equals 30 lines of pica, and so on, he can go through with the work of clothing his formes much more confidently and swiftly. Furniture along the sides of pages should be two ems longer than the page, to prevent any possibility of the type slipping out; but the furniture at the heads should always be exactly the measure of the line. This makes a solid forme, and obviates the danger of the side furniture being jammed against the head furniture in the locking up.



27. A LOCKED-UP FORME
(H. W. Caslon & Co.)

The Forme as "Locked Up." Place the sidesticks and footsticks as before directed, and then take the cords off the pages, winding them into hanks at the same time. If possible, a chase should always fit the forme; but if not, the space between the iron frame and the "sticks" should be carefully filled in with good wood furniture or worn metal furniture, till it comes to within the breadth of fair-sized quoins. The quoins having been pressed in, apply the planer to the whole surface of the forme, page by page, and then lock up. Again plane with mallet and planer, this time firmly, and the forme is ready to lift. If the type has been properly set, and the forme firmly locked up, the whole ought to lift solid as a board. During the past 20 years, patent metal quoins, formerly disliked as innovatious, have gradually gained wide acceptance in the trade. As shown in our illustration of a locked-up forme [27] these quoins are wedge-shaped pieces of metal, grooved so as to fit into each other, and toothed on the inner edges for the pinions of the screw-key. Using these we can surround the type with plain furniture, and by opposing the wedges to each other, by means of the key, lock up the forme.

Sheet Signatures. For the purpose of distinguishing one sheet of a book from another, the practice of putting a letter at the foot of the first page of the outer forme was early adopted. By this sign the compositor, the machine man, and bookbinder can tell at a glance what sheet they are working with, and whether or not the pages are numbered correctly. A copy of the table given on the next page is often hung at the side of the imposing-stone.

The Reader. If the compositor always read his copy carefully, always picked up the right letter, always spelt correctly, punctuated faultlessly, read over each line before justifying, and were constantly alert and watchful, he would commit no errors, and, incidentally, be more than human. No man is uniformly in the best of health; the hand momentarily weakens, the attention falters, personal worries interrupt the thought concentrated on the work, and the errors slip past. In the printing world the errors are corrected by the proof-reader.

According to the best practice, a *proof-reader* is a compositor who, because he has produced work comparatively free from errors, and given evidence of self-education and interest in his craft, has been promoted. He sits in a room adjacent to the composing-room, or perhaps his place is on the same floor, and simply partitioned off by wood and glass. When the galley has been proofed on the galley-press, the copy is collected from the compositors, and the proof and copy carried to the reader. Beside the reader is his *copy-holder*, usually a boy, whose duty it is to read out the copy, while the reader scans the proof. The boy should have an aptitude for reading handwriting, and be easily trained to read clearly and correctly. As he reads along

the lines, the reader sees a turned letter, a letter "l" for a "t," and words variously misspelt, punctuation showing that the compositor has missed the sense of a passage, and swiftly marks the corrections on the margin of the proof. Listening carefully, he hears the boy say "traders" where the proof has it "leaders," and the general sense shows that the lad is right; the wrong word is struck out, and the right one written on the margin. By turning to page 4193, the student will find an example of the reader's practice, giving in full the signs of correction and the best methods of marking proofs.

Before sending out the proof, the reader should go over it a second time; he will thus be able to give undivided attention to the spacing and punctuation.

Office Style and "New" Spelling. Considering the number of readers employed in the printing trade, the vacancies offered to the youth ambitious of attaining the position are not numerous. Not that the changes are few. The compositor who is alert and ready finds his opportunity. But there is one factor which, small though it may seem, is very important. Every printing establishment has its own "style." In one place, the readers are instructed to punctuate widely, leave out as many commas as possible, where the sense of a passage appears clear without them. In another office the practice may be the very reverse. Similarly, the use of italics, the style of naming books, magazines, ships, and public institutions, capitals, placing the number of the date before or after the name of the month, and many other details are determined principally by that mysterious power called office tradition.

The English language is always changing in form. Though neither President Roosevelt nor the "Phonetikist" enthusiasts on this side of the Atlantic altered by one iota the spelling of the day, the language does change, both in pronunciation and spelling, by gradual degrees. A notable instance of change in spelling effected within twenty years is the almost universal substitution of "s" for "z" in such words as signify the endowment of a man or thing with a particular quality, as: Civilise, deodorise, mesmerise, and so on. The process is constantly going on, and the reader who would hold his place must keep himself informed on the subject.

Difficult Proof-reading. Reading revise proofs, proofs of author's corrections, and machine proofs are among the higher duties of the reader. The most experienced and skilful of the staff is entrusted with that work, and seldom has any other duty. Such a man performs a highly important function; he is president over the birth of many books, and he ought to possess, besides a thorough mastery of the details of his craft, wide, general knowledge, and a keen appreciation of English words.

Though the reader's chief tool is a well-stored and highly cultivated brain, he should be provided with aids in the shape of a small but select reference library. A good standard etymological dictionary, a classical dictionary, a dictionary of phrase and fable, Roget's "Thesaurus," a Bible, and an up-to-date stock of the more important year books and almanacs make a reasonable equipment. In addition, if the establishment is a large one, there ought to be a reference library readily accessible to the whole reading staff, stocked with the great compilations of authority, such as the "New English Dictionary," "Encyclopædia Britannica," works on technology, and dictionaries of the classical and leading modern languages.

The News Reader. The efficient reader is alert of eye and deft of hand, possessed of a good stock of general information, and fully acquainted with the forms of words, but the news reader's quickness and knowledge are taxed to a specially high degree. He must keep himself in touch with current affairs in politics, society, and life, know the names and politics of political leaders and members of Parliament; the topics of the hour, and the catch phrases of the moment. For lack of such a reader, the slips of the Parliamentary correspondent's pen have appeared in cold print, to the dismay of everybody concerned.

The news reader seldom has time to read matter twice; and sometimes he has to read the bare type. This means that he has to be quick, ready, able to detect not only errors in composing but all other errors at one reading. Very numerous are the traps into which the newspaper compositors may fall, and the reader has always to pull him up. Headlines may become mixed, the bottom or top line of a column may fall and be misplaced, and a hundred other accidents may happen, each one, perhaps, ruinous to the paper. The editor may be the greatest journalist alive; his staff may be the flower of English journalism, and yet the inefficiency of a reader can ruin everything.

Continued from page 5367

By CLAYTON BEADLE and HENRY P. STEVENS

COAL-TAR PRODUCTS

Coal-tar products are the result of subjecting coal to the process known as *destructive distillation*. By this we understand the decomposition of substances (in this case coal) by heat with the formation of products which are volatile. Destructive distillation differs from ordinary distillation in that the substances do not distil unchanged, and the products collected differ in chemical composition from the substances from which they were obtained. The plant required for carrying out processes of this kind does not differ essentially in principle from that employed for the purification and preparation of bodies by distillation. It consists, first, of a vessel or a retort in which the substance is heated and undergoes decomposition; secondly, a condenser, or apparatus for the condensation of the vapours given off; and thirdly, a receiver or receptacle for collecting and separating the products of distillation.

Constructive Distillation. Although the process may be regarded mainly as the breaking-up of more complicated products into simpler ones, nevertheless, alongside of this decomposition a certain amount of *synthesis*—that is, building-up of chemical compounds, or formation of substances—takes place from the first-formed products of decomposition. This is owing to the fact that such products of decomposition are not removed immediately they are formed, but remain for a certain time in the hot retort. Thus, if benzene be led through a red-hot tube, a certain proportion of acetylene is formed. On the other hand, acetylene led through a red-hot tube is partly converted into benzene. Now, as benzene and acetylene are both formed on the destructive distillation of coal, we see that the formation of either of these substances is not the simple process of decomposition which it might appear to be at first glance.

Coal-tar. An enormous amount of this substance is produced yearly, and most of it is derived from the destructive distillation of coal. The coal carbonised in London and surrounding districts in 1902, according to private sources of information, we find to be nearly 4,000,000 tons, yielding, say, 200,000 tons of tar. The yield of tar will depend upon the variety of coal and temperature of distillation, etc.

Tar is a liquid heavier than water, its specific gravity being 1·1 to 1·2. The composition of the tar will depend upon the quality of the coal. Thus, cannel coal yields a tar of specific gravity 1·1, poor in aromatic compounds. Newcastle coal gives tar rich in naphthalene and anthracene, and Wigan coal gives tar rich in benzene and phenol (carbolic acid). Boghead and bituminous shales, when mixed with coals, give inferior tar containing excess of paraffin hydrocarbons, which cannot be separated from the tar by the usual processes.

The composition of tar is also largely dependent on the temperature of the retorts. At low temperatures, chiefly paraffin, olefins, and higher phenols are formed, and the quantity of the permanent gas produced is small. At higher temperatures, although olefins and also acetylenes are still formed, the paraffins are mostly decomposed, with the separation of carbon in the retorts and the formation of lower paraffins. There are also formed aromatic hydrocarbons and "condensed ring" bodies, together with lower phenols. The proportion of permanent gas is much larger than at lower temperatures. As almost all coal is a residue from the gasworks, and as prices of tar have been much lower of recent years, the object of the gasworks is to produce as much gas as possible, so that distillation is carried on at high temperatures, which tends to reduce the yield of tar. The temperature of working in England is about 1,100° C., and the average yield of tar may be taken as 5 per cent. The table below gives some idea of the yields of tar and gas liquor which can be obtained from one ton of different kinds of coal (Stohmann-Kerl):

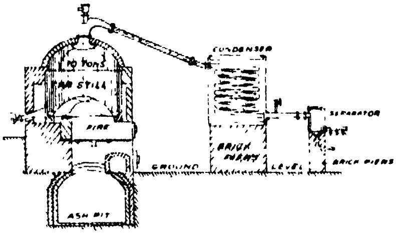
Coal	Tar	Gas Liquor
Boghead cannel	733 lb. ..	—
Newcastle	98 ,, ..	60
Wigan	218 ,, ..	162
Lochgelly	225 ,, ..	340
Pelton Main	112 ,, ..	112
Lismahago cannel (1) ..	594 ,, ..	4
,, ,, (2) ..	603 ,, ..	4
Ramsay's Newcastle cannel	295 ,, ..	7
Derbyshire deep seam ..	219 ,, ..	179

Coal-tar is also obtained in some cases by utilising the waste products from coke ovens. Small quantities are also obtained from blast furnaces, gas producers, and water-gas plants.

Crude Tar. Although a number of valuable products are got by distilling coal-tar, some outlet can be found for it in the crude state. In the first place, it can be burnt as fuel. This is usually done underneath the retorts themselves by running the tar on coke. In this way, one part of tar may be burnt for every four parts of coke. A number of appliances have been devised for burning tar in a furnace in a similar manner to petroleum. It may also be used for preserving timber and other building materials, and as tarred felt for roofing, or again as an antiseptic in virtue of the carbolic acid, etc., that it contains. It is, however, more usual to separate these substances than to make use of the tar itself.

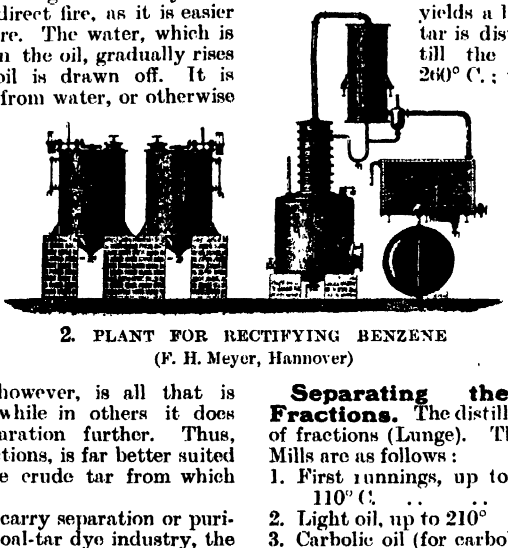
Tar forms a suitable substitute for resin in the preparation of lampblack; but a partially purified or prepared tar is now used, as the crude tar contains some very volatile constituents, and these would find their way into the lampblack. It is usual to remove these by first distilling off the water and more volatile portions of the tar. The tar is burnt in brick ovens, and the soot is deposited in a number of chambers. Several contrivances have been devised for bringing about rapid deposition of the soot, such as systems of "baffle-plates"—that is to say, obstructions built into the flues, not unlike the arrangement of laths in a venetian blind, and devices for giving a whirling motion to the soot-charged vapours, so that the particles of soot strike the walls of the collecting chambers and are deposited. Lampblack contains a certain quantity of tarry matter, and for many purposes it requires to be refined. This is done by igniting in sheet-iron cases with lids luted on. After ignition, the cases are left some time to cool, as soot loses its heat slowly, and would catch fire if exposed to the air while still hot. The refined product has a better covering power [see Paints and Polishes, page 5141], and is used by printers' ink and colour makers [see Inks, page 5366]. Tar has also been used as a binder for briquettes, and for making the "basic" lining of Bessemer converters.

Distillation of Coal-tar. Coal-tar is a mixture of a great number of different substances. Lunge, in his treatise, gives a list of nearly 200, many of which are extremely valuable, and are the mother substances for the manufacture of aniline dyes, artificial perfumes and essences, pharmaceutical preparations and disinfectants. The problem we have to face is the separation and the purification of the individual substances. Although the actual proportion of some of these substances present in the tar is very small, the quantity of tar worked up is so large that considerable amounts of these substances can be obtained. Thus, the yield of anthracene, the mother substance of the alizarine dyes, is less than 1 per cent. of the tar distilled.



1. GENERAL ARRANGEMENT OF TAR DISTILLING PLANT
(Leeds and Bradford Boiler Co., Ltd.)

The tar is first freed as completely as possible from watery ammoniacal liquor, which distils over from the retorts with the tar [see Coal Gas, and also Sulphuric Acid, page 4625, and Alkalies, page 4770]. This is often effected by allowing the tar to stand in cisterns preferably fitted with steam coils. By a steam coil is meant a coil of steam pipe by which the liquid in the cistern can be heated. Such indirect methods of heating are in many cases preferable to heating by a direct fire, as it is easier to regulate the temperature. The water, which is merely held mechanically in the oil, gradually rises to the surface, and the oil is drawn off. It is important to free the tar from water, or otherwise it might "bump" or boil explosively when distilled. Distillation is the method used to separate the constituents of which coal-tar is composed, but the method allows of only a very rough separation in one operation. The different portions or "fractions" of the distillate collected are in themselves complex mixtures. This partial separation, however, is all that is necessary in some cases, while in others it does not pay to carry the separation further. Thus, creosote oil, one of the fractions, is far better suited for "creosoting" than the crude tar from which it was obtained.



2. PLANT FOR RECTIFYING BENZENE
(F. H. Meyer, Hannover)

Where it is necessary to carry separation or purification further, as in the coal-tar dye industry, the fractions are themselves redistilled, and various other chemical means are employed which we shall briefly touch on in what follows.

The Coal-tar Still. The coal-tar is treated in stills, mostly upright and cylindrical in form, the bottom being spherical and curved inwards, as in the illustration. Figure 1 shows the general arrangement of still, condenser, and separator; 3 is a photograph of the still lying on one side. The still is provided with a dome-shaped cover and still head, inlet and outlet cocks, and manhole. It should also be fitted with some form of safety-valve. Modern plants are often provided with a system of steam pipes, reaching to the bottom of the still, so that superheated steam can be used for finishing off the process. The condenser is simple in construction, put together from lengths of cast-iron pipes with elbow joints or from semicircular wrought-iron tubes. The condensing worm so formed lies in a cooling tank, as in an ordinary still. Noxious gases are given off during the distillation, and carry with them a small proportion of the more volatile constituents. They must be treated in a "scrubber," not so much to recover these constituents, but to absorb the noxious gases such as CS_2, H_2S and NH_3, before they escape into the air.

Gaster's Process. We must take especial care in working the stills that the contents do not boil over, especially when the distillation begins. According to Kohler, this is often caused by an excessive percentage of *free carbon*. This free carbon, which may be present in the tar to the extent of 20 per cent. to 25 per cent. by bulk, has a tendency to settle down to the bottom, and as it is a bad conductor of heat, there is considerable danger of overheating and burning out the bottom of the still, especially during the last stages of the operation.

Gaster has patented a method of separating the carbon, itself of considerable value, for making electrodes [see Electrochemistry]; further, the oil freed from carbon distils better and yields a better class of pitch. The tar is distilled in the ordinary way, till the temperature rises above 260° C.; the operation is then interrupted and a low boiling naphtha added to the partly cooled contents of the still. The whole is forced into a filter press, where the carbon is retained and washed by a further quantity of naphtha to remove the rest of the tarry matter. The carbon is left as fine powder, and the tar oil, after distilling off the naphtha, can be further treated as required.

Separating the Distillate into Fractions. The distillate is collected in a number of fractions (Lunge). The average yields given by Mills are as follows:

1. First runnings, up to 105° C. or 110° C.	2·5 per cent.
2. Light oil, up to 210°	5·0 „
3. Carbolic oil (for carbolic acid and naphthalene up to 240° ..	27·5 „
4. Creosote oil, up to 270° ..	
5. Anthracene oil, above 270° ..	10·0 „
6. Pitch (with this yield the pitch is hard)	55·0 „

The more important substances obtained from these several fractions are indicated by the titles. The "first runnings," consisting of naphtha, come over with some aqueous ammoniacal liquor and float upon it.

The "light oils," or "second runnings," are collected until they appear neither to sink or to float in water—that is to say, until they are as heavy as water. This fraction consists of benzene, toluene and "higher homologues" [for which see Organic Chemistry], and a certain amount of carbolic acid, naphthalene and other substances. The greater part of the carbolic acid and naphthalene are contained in the third fraction, the "carbolic oil," and as naphthalene is a solid substance at the ordinary temperature, the solidification of a few drops of the distillate on a piece of cold iron shows when it is time to change the receiver and to begin collecting the carbolic oil.

The Light Oils and their Treatment. To separate the substances contained in the light oils, they are fractionally distilled or rectified in a plant similar to a tar still.

Wurtz states that after two fractionations, the following results are obtained:

(*a*) Product up to 120° containing benzene and toluene.

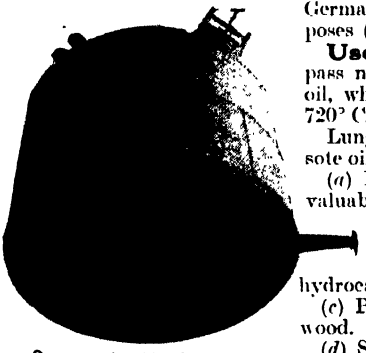
(*b*) Product from 120° to 127° containing solvent naphtha No. 1.

(*c*) Product from 127° to 140° containing solvent naphtha No. 2.

(*d*) Product from 140° to 150° containing solvent naphtha No. 3.

(*e*) Residue, which will contain the phenol and naphthalene.

Product (*a*) is further purified by washing with chemicals, usually strong sulphuric acid and alkali. Plant for doing this is described under Washing Turpentine [see Wood Distillation]. It then undergoes further rectification by steam. The plant is shown in 2; on the left are the two washers, and on the right the distilling plant.



3. TAR STILL, SHOWING CURVED BOTTOM
(Leeds and Bradford Boiler Co., Ltd.)

Benzene is a body of great importance, as it can be converted into nitrobenzene or oil of mirbane, a substitute for oil of bitter almonds, and thence into aniline, the mother substance of many of the aniline dyes. The United Kingdom produces several million gallons of benzene yearly. Benzene and naphthalene are also used for solvent purposes, and for carburetting coal gas.

Carbolic Oil and Carbolic Acid. We now pass to fraction 3, the carbolic oil, which forms 7 per cent. or 8 per cent. of the total distillates. On cooling down, 25 per cent. to 30 per cent. of the naphthalene crystallises out. This substance is one of the most abundant constituents of coal tar, of which it forms 5 per cent. to 10 per cent. In the crude state it is used for carburetting gas. It is purified by hot-pressing—that is to say, pressing out the mother liquor while the mass is hot. [For chemical and physical characteristics of naphthalene and other bodies derived from coal tar, see Organic Chemistry.]

Naphthalene is the mother substance for making phthalic acid, and thence the phthalein colours, as for instance, eosine and phloxine, also β-naphthol and azo-dye derivatives, and in the manufacture of artificial indigo. The oil, from which the greater part of the naphthalene has crystallised out, is separated by a very beautiful chemical process devised years ago by the French chemist Laurent. It is treated with alkaline liquor (carbonate of soda), which combines with the carbolic acid, phenols and higher monologues (cresols), in virtue of their acid natures. The mixture left to itself will separate into two layers, an oily and an "aqueous" or watery layer, so that the resulting salts, carbolates, being soluble in the aqueous layer, can be removed, and the remaining oil contains higher "homologues" [see Pure Chemistry] of benzene, naphthalene, and pyridene bases. The operation is carried out in mechanical mixers, heated and agitated by a current of air or other means. [Illustrations representing similar mixers to these may be seen in the article on Wood Distillation.] As phenol is a stronger acid than the cresols, most of it may be removed from the oil, leaving the cresols behind, by adding alkali in successive small quantities. The liquor containing the carbolates is decomposed with sulphuric acid in a lead-lined "agitator" or "mixer."

Pure carbolic acid is obtained by distilling; the distillate passing over between 180° and 205° C., is allowed to crystallise and the crystals are separated from the mother liquor. The carbolic oil contains some pyridine bases, which are used largely in Germany for "denaturing" purposes (rendering spirit undrinkable).

Uses of Creosote Oil. We pass now to fraction 4, the creosote oil, which distils between 240° and 720° C.

Lunge describes the uses of creosote oil as follows:

(*a*) Rectification, to obtain more valuable products.

(*b*) Passing through red-hot tubes, to obtain illuminating gas, and more readily saleable hydrocarbons.

(*c*) Pickling timber to preserve the wood.

(*d*) Softening hard pitch.

(*e*) Preparing varnishes.

(*f*) Lubricating oil, either in the crude state, or after undergoing special treatment.

(*g*) Burning for heating purposes.

(*h*) Burning for lampblack.

(*i*) Lighting.

(*j*) Carburetting gas.

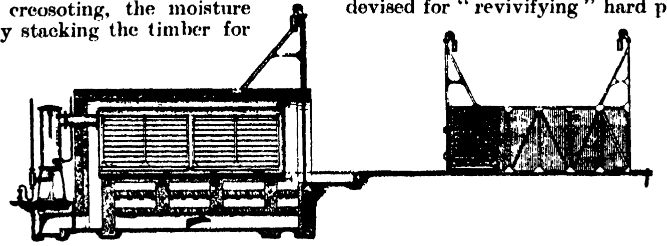
(*k*) As an antiseptic.

(*l*) Blue steaming of bricks.

For lubricating purposes the phenols ("acids") must first be removed. This is commonly effected by means of lime, which, being alkaline, combines with phenols, just as in Laurent's process. The resulting oil, when mixed with rosin oil and ozokerit (earth wax) yields a serviceable cart grease. For lighting purposes it is burned in special lamps, and produces a bright, roaring flame, such as may be seen in the streets at night where road repairs or building operations are carried on. As for antiseptic purposes, it would be better to separate those substances such as phenol, cresols, etc., to which the antiseptic properties of the oil are due. Owing to the expense of this treatment, the untreated oil is used in the form of an emulsion by mixing with a soap such as a soda rosin soap [see Soaps, page 4963]. It will owe its activity as a disinfectant to the finely-divided state of the phenols, when prepared in the form of emulsions. Such substances are sold as "creolin," "cresolin," "disinfectol," etc. Others, "sapocarbol," "lysol," are prepared

(German Patent 52,129) by mixing the oil with resin or linseed oil and saponifying with caustic potash and spirit of wine under a "reflux" condenser. Thick oils are thus obtained which have the advantage of dissolving easily in water.

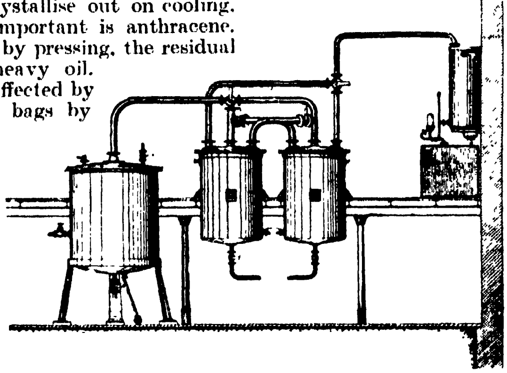
Pickling Timber. For preserving wood, *creosoting* is more commonly adopted than any other method (others consist in heating wood with solutions of corrosive sublimate, zinc chloride or copper sulphate). Before creosoting, the moisture must be removed by stacking the timber for six months or so. The operation is carried out in special plant. The wood is put into a boiler capable of withstanding considerable pressure. The air is then exhausted and hot oil run in to fill the whole boiler with the exception of a dome situated on the top. The air exhaust is kept working, and, under the influence of the hot oil, all air and moisture is withdrawn from the pores of the wood. The contents of the boiler are then subjected to pressure, by which the oil is driven into the pores, from which the air has been sucked out. In this process (Boulton, British Patent 1854-1879) wet, unstacked wood can be used without previous treatment. The method of creosoting or pickling can also be applied to sails, ropes, fishing-nets, etc.



4. HORIZONTAL RETORT, WITH COOLING-BOX FOR THE CHARCOAL

According to Williams, pyridene and quinoline bases are the active constituents in preserving timber. The creosoting is, however, both a chemical and mechanical process, and the "indifferent oils" play an important part, leaving out of consideration the chemical effect of the phenols and the acids. The oil being forced into the wood seals the pores and prevents the entrance of water.

The Mother Substance of Many Dyes. We come now to fraction 5, the anthracene oil (green oil, green grease, red oil), which boils above 270° C. (thermometer in vapour). It consists largely of solids, which crystallise out on cooling, and of which the most important is anthracene. These solids are separated by pressing, the residual oil going back to the heavy oil. This separation may be effected by filtering through canvas bags by means of filter or hydraulic presses. The residual mass contains about one-third its weight of anthracene. It is then powdered and washed with naphtha in closed iron cylinders provided with mechanical agitators and heated by a steam coil. The naphtha is, of course, recovered by distillation. It leaves behind a number of hydrocarbons, especially phenanthrene [see Organic Chemistry], which are used for making lampblack.



5. PLANT FOR TREATING CRUDE DISTILLATE. TRIPLE STILL SYSTEM

Crude anthracene is a brownish-green mass. Final purification is effected by sublimation. In England a larger yield of anthracene (London tar 0·8 per cent. to 0·9 per cent.) is obtained than on the continent (German and Dutch works, 0·3 per cent. to 0 4 per cent.). The United Kingdom produces about 6,000 tons of a 30 per cent. product annually. Germany consumes 1,400 tons *pure* anthracene in the alizarine dye works.

Coal-tar Pitch and its Uses. The residue left in the retort will vary in quality according to the amount of oil distilled off, yielding either a soft or hard pitch. For the manufacture of patent fuels soft pitch is preferred, and processes have been devised for "revivifying" hard pitch, by incorporating with it creosote oil or crude tar. Tar pitch is is largely used for making varnishes [see Paints and Polishes, page 5141], and also as asphalt for paving. In the latter case it is a substitute for natural asphalt, but only in combination with the latter [see page 2425]. Pitch may also be redistilled in special ovens in order to obtain a further yield of the valuable anthracene. Coke is left behind at the end of the operation.

WOOD DISTILLATION

In the various countries where there is a plentiful wood supply, particularly in Scandinavia, Germany, and North America, a portion of the output is utilised in the manufacture of chemical products by subjecting the wood to destructive distillation.

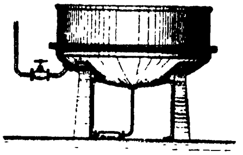
Wood consists essentially of 30 per cent. to 60 per cent. cellulose with about 12 per cent. of moisture and a small quantity of resin, mineral matter, etc. After deducting moisture, common woods contain about 50 per cent. of carbon and 6 per cent. of hydrogen.

The effect of heating is, in the first place, to drive off water, after which the wood begins to char and volatile decomposition products are given off, which are condensed by suitable means. They consist chiefly of methyl alcohol or wood spirit, tarry substances, and a weak solution of acetic acid, which collect in the receiver, while charcoal remains behind in the retort. Gases consisting mostly of carbon monoxide, carbon dioxide, and marsh gas, are also evolved. The charcoal is directly marketable. The gases are usually led back and burned under the retorts while the distillate is worked up on the following lines.

It is first roughly separated into aqueous liquor and tar. The aqueous liquor, which consists mainly of weak acetic acid, termed *pyroligneous* acid, can be employed directly for making iron mordant by dissolving scrap iron in it, the product consisting of a mixture of impure ferrous and ferric acetates, the so-called black liquor or iron liquor. Or litharge may be dissolved in it, and the resulting sugar of lead purified by crystallisation. It is, however, more usual now to subject the crude pyroligneous acid to a careful separation. The liquid, which is dark brown in colour, and has a strong empyreumatic odour, consists in the main of:

5 to 10 per cent. of acetic acid
0·1 „ 0·2 „ „ acetone
1·5 „ 3 „ „ wood spirit (methyl alcohol)
6 „ 10 „ „ tar
77 „ 87 „ „ water
and other products.

The acid is distilled, and the vapours led through milk of lime, which combines with the acetic acid and any other acid substances, while the greater part of the steam and wood spirit vapours pass on, and are collected in a suitable condenser.



6. PAN FOR CONCENTRATING CALCIUM ACETATE LIQUORS

Crude Products and Yields. We now have our crude products separated in three parts:

1. The tar which remains behind in the retort.
2. The solution of calcium acetate with a concentration of about 15 per cent.
3. The solution of wood spirit in water—of from 6 per cent. to 10 per cent. strength.

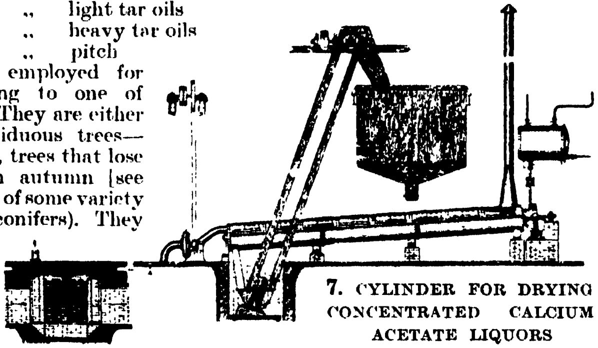
The crude calcium acetate liquors yield on concentration a *grey* calcium acetate containing 80 per cent. to 84 per cent. of the pure acetate which serves as raw material for the preparation of acetic acid and acetates. A brown acetate of lime is also manufactured containing 60 per cent. to 70 per cent. of the pure acetate. The crude wood spirit is rectified in special distilling plant (dephlegmators) fitted with condensers, and yields an 80 per cent. wood spirit, the raw spirit of commerce.

Returning now to the larger quantity of tar separated mechanically from the aqueous liquors, if this tar be distilled it can be separated into a liquor containing some acetic acid and wood spirit, a light and a heavier tar, and, finally, wood pitch (Stockholm tar), which remains behind in the stills.

The yields are approximately as follows:

20 per cent. of acetic acid and wood spirit
5 „ „ light tar oils
10 „ „ heavy tar oils
60 „ „ pitch

The woods employed for distilling belong to one of two classes. They are either woods of deciduous trees—that is to say, trees that lose their leaves in autumn [see page 4676]—or of some variety of pine tree (conifers). They are treated on somewhat different lines. The wood of deciduous trees yields a maximum of wood spirit and acetic acid, while the tar is of little or no value. On the other hand, the wood of pine trees, of which usually the stumps and roots are employed, yields, in addition to a small quantity of wood spirit and acetic acid, a valuable pitch (Stockholm tar) and some turpentine.



7. CYLINDER FOR DRYING CONCENTRATED CALCIUM ACETATE LIQUORS

According to Rudnew the acetic acid obtained from 100 parts of different kinds of wood is as follows:

Linden ..	10·24 parts	. .. .	5·2 parts
Birch ..	9·5 „	Cellulose from	
Aspen ..	8·06 „	birch ..	6·2 „
Oak ..	7·9 „	Cellulose from	
Pine ..	5·6	pine	5·0 „

The wood was "distilled" from glass vessels at 150° C. to 300° C.

The Still in Operation. We will now describe in more detail the process of distilling wood and the preparation of acetic acid, acetates, methyl alcohol and acetone.

Before the wood can be put into retorts for distillation it has to be stacked for one or two years in order to get it as dry as possible. It is taken from the drying sheds, put on to small trucks, and taken to the retorts. These consist of horizontal cylinders [4], which are heated so that the flames do not come into direct contact with the metal, but are arranged so that the hot flue gases surround them. This is necessary to prevent over-heating of the retorts and to subject the wood to as uniform a temperature as possible.

The water and other products formed are carried into tubes surrounded by a cold water-jacket, arranged so that they can be readily cleaned out should they get stopped up at any time. In these tubes the whole of the volatile matters are condensed with the exception of the gases. The former collect in a vessel or receiver. On their way they pass through a small separator, and a pipe from this leads the gases back to be burned under the retort. A number of these retorts are arranged alongside one another.

In the first stages the distillate is clear, and has little odour, being almost free from acetic acid and tar, but later on the distillate becomes darker in colour owing to the presence of a considerable proportion of tar, while gases are given off in larger quantities. In the final stages the gas evolution slackens, and the condensed liquids consist almost entirely of tar. When the distillation is complete, the front of the oven is opened, and workmen immediately seize hold of the basket in which the wood lay in the retort and draw it out. As soon as the hot charcoal comes into contact with the air it catches fire. This is put out by sprinkling it with a little water, and the charcoal is allowed to cool in an iron vessel with the lid well luted on, so as to prevent access of air. The cooling-box is seen on the right-hand side of **4**. The distillate from the different retorts collects in large wooden vats, where the tar separates out, and is run out from a tap at the bottom from time to time, while the aqueous liquors overflow from the vat into a series of vats—five in all—where the tar settles. In the last vat practically no tar at all is found.

Separation of the Products. The crude aqueous liquors are pumped up into a cistern, whence they are run into a large copper retort [5], which is in connection with two smaller copper vessels containing the milk of lime. The large retort is heated by a steam coil, and the products, consisting chiefly of methyl alcohol and acetic acid, are driven over and collect in the smaller vessels containing the milk of lime (triple still system). The plant is arranged so that the vapours pass through either or both of the milk of lime vessels. The greater part of the steam and methyl alcohol pass on, and are condensed in a suitable condenser, seen on the right hand of **5**.

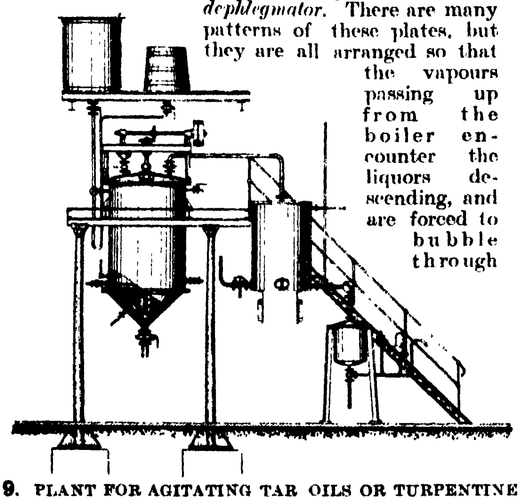
The specific gravity of the distillate is taken continuously by running the liquor through a vessel provided with an hydrometer. The first portions, being much richer in methyl alcohol, show a low specific gravity. When the instrument shows that the specific gravity of the condensed vapours is practically equal to that of water, it may be taken that the whole of the methyl alcohol has been driven off. There is, therefore, no need to condense the vapours, which come over in the latter part of the operation, as they consist wholly of steam.

Take the case of 1,000 gallons of crude liquor from beech wood, which will contain about 275 lb. of wood spirit: at least 270 gallons of weak aqueous wood spirit will distil over before the whole of the wood spirit is condensed. The first portion, containing 30 per cent. to 40 per cent. of methyl alcohol, is usually collected apart in a separate tank: the weaker liquors, containing up to 15 per cent. of wood spirit, are also separately collected.

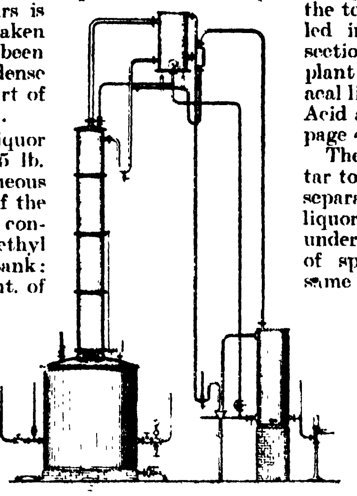
Before all the wood spirit is driven out of the big copper retort in which the liquor was originally placed the acetic acid will begin coming over, and as soon as the milk of lime in one of the smaller vessels shows an acid reaction to litmus it is run out, and the vapours and steam led into the second vessel. The crude acetate of lime collects in tanks, and contains about 20 per cent. of calcium acetate, so that a large quantity of water must be driven off before the commercial dry calcium acetate, containing about 80 per cent. pure acetate, can be obtained.

This concentration of the liquors is not easily carried out, because at a certain stage the material gets into a pasty condition and requires considerable mechanical force to keep it stirred to prevent any of it being overheated. The concentration is usually effected in a jacketed steam pan [6], and the concentration carried only to a certain stage, when it is transferred to a cylindrical drier with internal revolving arms. These arms are provided with scoops. Hot air passes up the cylinder, which is set at an inclination so that the material travels down the cylinder, leaving it in the dry state at the lower end, whence it is elevated to a storage bin [7].

The crude methyl alcohol, which is only about 10 per cent. strength, is rectified in a special plant [8] consisting of a boiler heated with a steam coil, on which stands a tower divided into a great number of compartments by perforated plates, termed a *dephlegmator*. There are many patterns of these plates, but they are all arranged so that the vapours passing up from the boiler encounter the liquors descending, and are forced to bubble through them. In this way the portions containing water are returned to the boiler, while the more volatile portions, consisting of methyl alcohol, escape from the top of the tower and are led into a condenser. A sectional drawing of similar plant for treating ammoniacal liquors is shown in the Acid and Alkali section [20, page 4776].



9. PLANT FOR AGITATING TAR OILS OR TURPENTINE WITH CHEMICALS, AND DISTILLING THE PRODUCT



8. PLANT FOR RECTIFYING WOOD SPIRIT (METHYL ALCOHOL)

There remains only the tar to be dealt with. That separated from the aqueous liquors is usually burned under retorts by means of sprays, in exactly the same manner as coal-tar is burnt.

The larger quantity of crude tar is subjected to a distillation to recover the acetic acid and methyl alcohol contained in it.

Coniferous Woods. The foregoing description applies chiefly to beech wood and the wood of other deciduous trees, and requires some modification if applied to pine woods, as the latter contain resin, which yields turpentine when the wood is distilled.

As turpentine is a valuable product, the distillation of pine woods is a profitable operation, in spite of the much smaller yield of acetic acid and methyl alcohol. The turpentine collects in the same receiver with methyl alcohol, after the vapours driven off from the large retort have passed through the milk of lime, and separates out as a distinct layer, which may be drawn off.

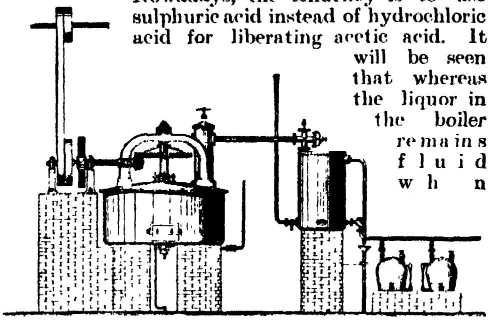
Owing to the presence of small quantities of allyl compounds, it has a penetrating smell, and the vapours irritate the eyes. No amount of further distillation will rid the crude turpentine of this impurity, and recourse is had to chemical treatment. The crude turpentine is run into an iron vessel provided with mechanical agitators [9], and a quantity of caustic soda liquor added. This extracts some of the impurities, such as aldehydes, phenols, etc., the liquor changing to a brown colour. It is run off, and the oil washed with water in a similar manner—that is, water is run in, the agitators set going, and after sufficient treatment the water run off again. Following this washing with soda, the crude turpentine is treated in a similar manner with sulphuric acid, and finally rectified.

Acetic Acid. As already mentioned, the crude sodium acetate is the material from which the pure acetic acid is prepared. For this purpose the sodium acetate is acted on with either hydrochloric or sulphuric acids. For 100 lb. of calcium acetate 115 lb. of hydrochloric acid of 20° to 21° B. is required. The two are thoroughly stirred up and allowed to stand, when the small quantity of tar contained in the acetate of lime rises to the surface and is skimmed off. The liquor is then heated in copper boilers by means of steam coils, and the acetic acid vapours are driven off and condensed.

Theoretically, 100 parts of the crude grey acetate of lime, containing 82 per cent. of the pure substance, should yield 60 parts of glacial acetic acid; but this yield is never obtained in practice, as a certain amount of acetic acid is held back by the chloride of calcium liquor remaining in the boiler.

Acetic acid prepared by this method is usually of about 45 per cent. strength, and as such is brought into the market. It could be concentrated by rectification, in plant built on similar lines to that used for rectifying methyl alcohol [8].

Nowadays, the tendency is to use sulphuric acid instead of hydrochloric acid for liberating acetic acid. It will be seen that whereas the liquor in the boiler remains fluid when using the latter acid, this is not the case when working with sulphuric acid, as insoluble calcium sulphate is formed in the reaction. This necessitates fitting the boiler with mechanical stirrers [10].



10. PLANT FOR MAKING CRUDE ACETIC ACID BY SULPHURIC ACID PROCESS

Further, when using sulphuric acid certain other decompositions take place simultaneously, with the result that some sulphur dioxide is formed, and the acid is not so pure as that obtained by the hydrochloric acid process. The difficulty may be got over by adding an oxidising agent, such as pyrolusite, to the contents of the still. The sulphuric acid process has, however, this great advantage, that as the liquor is not diluted, the acetic acid is obtained in a more highly concentrated state—that is, as high as 75 per cent.

The more concentrated the acid the higher the temperature at which it boils. By distilling in a suitable retort, fitted with a dephlegmator, the most concentrated acid—the so-called *glacial* acetic acid—is obtained. The term "glacial" is given to it on account of its property of solidifying to a hard, ice-like mass in moderately cold weather.

In many cases it still contains a little sulphurous acid and other organic impurities. To obtain the absolutely pure acid for pharmaceutical or similar purposes, it is distilled over permanganate or bichromate of potassium in a copper retort provided with a silver condenser. It should be colourless and water clear, and should not decolorise a solution of potassium permanganate.

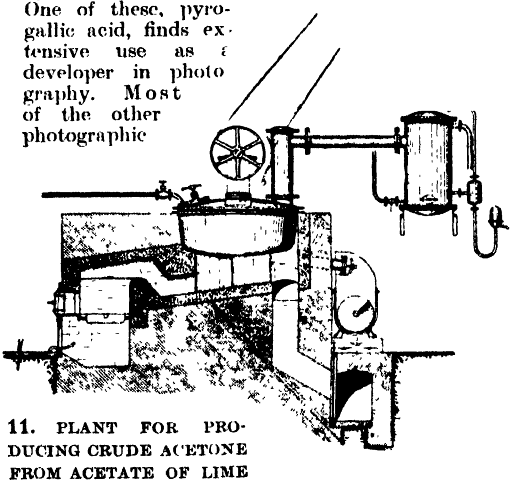
Acetone. Acetone is prepared in large quantities for use in the celluloid industry, and for gelatinising nitro-cellulose in the manufacture of smokeless powders. Very large quantities are imported into this country by our Government for this purpose. Acetone is obtained on a large scale by distilling calcium acetate. Special forms of retorts are employed, sometimes provided with stirrers similar to those used for making acetic acid by the sulphuric acid process [11].

The yield obtained depends very much upon the manner in which the crude material is heated, and the retorts are arranged so as to be surrounded by the hot flue gases. At first, water distils over, as even "dry" acetate of lime contains some moisture in combination, after which nothing comes over for a little while, until the acetone itself makes its appearance as a dark brown distillate with a characteristic odour.

During the process, inflammable gases are given off, owing to secondary decompositions, and these gases must be removed from the retort by a steam jet before the latter can be opened. 240 lb. of crude acetate of lime yield about 22 lb. of crude acetone, and the jet of steam led into the retort at the end of the operation carries over about another 4 lb. The illustrations in the wood distillation section are from machines constructed by F. A. Meyer, Hannover-Hainholz.

Coal-tar and Wood Products. The different products obtained in the distillation of coal and wood form the raw materials for the manufacture of a host of valuable substances which include most of the disinfectants and dyes, as well as synthetic remedies, artificial perfumes, and saccharin. From the chemical point of view, the composition of these substances is extremely complicated, and their manufacture not less so. A thorough knowledge of organic chemistry is necessary for anyone who desires to follow, step by step, the stages by which these substances are built up from such mother substances as benzene, toluene, phenol, cresol, naphthalene, and anthracene. Besides these coal-tar products, we have the acetic acid, acetone, and methyl alcohol as raw materials obtained from wood. We must, therefore, content ourselves in the majority of cases with a bare enumeration of some of these products. It will be realised that even this must be done inadequately, when we consider that there are, for instance, several hundred coal-tar colours known.

Disinfectants. For use as a disinfectant, a chemical substance is not required in a high state of purity, and consequently we have already had occasion to mention phenol and cresol, and other products of the distillation of coal, which may be applied in the crude state. A number of other disinfectants which have been prepared possess a similar chemical constitution, and are known as hydroxy derivatives of benzene and its homologues. One of these, pyrogallic acid, finds extensive use as a developer in photography. Most of the other photographic developers are similarly constituted, but of more complicated constitution. We should not omit to mention a valuable disinfectant called *formaline*, consisting of a 40 per cent solution of formaldehyde, obtained by passing a mixture of air and the vapour of methyl alcohol (wood spirit) over hot copper oxide.



11. PLANT FOR PRODUCING CRUDE ACETONE FROM ACETATE OF LIME

Excess of methyl alcohol is always used in practice, and some 30 or 40 per cent. unacted upon is recovered in a subsequent operation. The greatest care is necessary in maintaining the right proportions of methyl alcohol vapour and air, otherwise disastrous explosions may take place, or else the oxidation may go too far, so that the whole of the formaldehyde is oxidised to formic acid, with rise of temperature.

Coal-tar Colours. These are sometimes incorrectly termed *aniline dyes*, for although some of the more important are derivable from aniline and its congeners, this is by no means always the case. The aniline dyes are, in the first instance, derived from benzene, toluene, naphthalene, and other hydrocarbons, by acting on them first with nitric acid, to give the corresponding nitro-compounds, of which nitro-benzene is the simplest representative.

It is a yellow oil, smelling of almonds (essence of mirbane). These nitro-compounds are reduced with iron or zinc in hydrochloric acid solution, yielding aniline, toluidene, naphthylmine, etc.

$$\underset{\text{Benzene}}{C_6H_6} \rightarrow \underset{\text{Nitro-benzene}}{C_6H_5 . NO_2} \rightarrow \underset{\text{Aniline}}{C_6H_5 . NH_2}$$

Aniline is a colourless oil of peculiar odour, which, together with analogous substances, yields the dyes of the rosaniline group, including magenta and fuchsine, and a great number of others. There are also the indulines and safranines, "basic" dyes of a blue or darker shade. [For an explanation of the terms "basic," "acid," "adjective," and "substantive" dyes, see Paints, page 5141]. Aniline black, made by carefully oxidising aniline, is of importance in cotton printing. Methylene blue is an important sulphur containing dye. Passing from the aniline dyes we come to the phenol dyestuffs—mostly acid dyes—nitro-derivatives of the phenols. Picric acid (trinitro-phenol), a strong, yellow dye, may be taken as an example. One part in 1,000 will dye silk a distinct yellow. Victoria yellow and Martius' yellow are other dyes of this class. Naphthalene oxidised to phthalic acid combines with the phenols to yield the phthaleïn colours; some of the best known are erythrosine, eosine, and phloxine. In addition, there are the rosolic acid and indo-phenol dyes.

Artificial Madder and Indigo. The third important group comprises the azo dyes. They are characterised by the azo grouping, composed of two nitrogen atoms ($-N = N-$), in combination with an amido (NH_2) group (amido-azo compounds) or a phenolic (OH) group (oxy-azo compounds). The simplest representatives will be:

Amido-azo benzene $C_6H_5-N=N-C_6H_4(NH_2)$

Oxy-azo benzene $C_6H_5-N=N-C_6H_4(OH)$.

Colouring matters of this type, but usually of more complicated constitution, are known respectively as *chrysoidines* and *tropœolines*. They are mostly yellow, brown, or scarlet dyes. As examples, we may cite Bismarck brown, crocein scarlet, and phenylene brown. Methyl orange, used as an indicator [see Acids and Alkalies] is also an amido-azo compound.

Anthracene is the basis of another important group, which includes alizarine (the artificial madder) and numerous other dyes, alizarine orange, alizarine blue, purpurine, and many similar substances.

Quinoline and acridine, two other coal-tar products, yield valuable dyes. Finally, we have artificial indigo, now manufactured on a commercial scale, and which is replacing the natural product. The chemical reactions involved in its manufacture are exceedingly complicated.

Artifical Perfumes and Flavouring Matter. Like the coal-tar colours we have just discussed, the nature of these substances is generally very complex, and they may conveniently be divided into two classes. There are, firstly, the synthetic products, which are, as far as we can judge, identical with the naturally occurring substances. Secondly, there are artificial products, usually mixtures, of different chemical substances, not identical with the natural product, but closely resembling it in odour or flavour.

Oil of Bitter Almonds and its Substitutes. To take the simplest instance we can think of, natural oil of bitter almonds is formed by the hydrolysis of a substance called *amygdalin*, which, owing to the presence of a natural ferment or enzyme (emulsin) occurring with it in the bitter almond, is decomposed (hydrolysed) with the formation of benzaldehyde, to which the odour and flavour of bitter almond is due.

Now, benzaldehyde, C_6H_5CHO, can be synthesised (built up) artificially from toluene, a hydrocarbon allied to benzene, occurring in the distillate of coal-tar. Hence benzaldehyde is to be regarded as a true synthetic product. Its manufacture on a commercial scale has been brought about through the following stages: (1) isolation and examination of the natural oil resulting in the elucidation of its chemical constitution; (2) the synthesis of this substance from simple commercial products, in this case toluene, as a result of laboratory work, based on purely theoretical considerations; (3) the adaptation and, if necessary, modification of laboratory work, to the conditions of commercial manufacture.

Leaving now the true synthetical products, we come to the second class of artificial substances. As a result of research in the laboratory, a substance, nitro-benzene, $C_6H_5NO_2$, was obtained by nitrating benzene. It is a yellow oil (benzaldehyde is colourless), having an odour strongly resembling oil of bitter almonds, and is largely used for flavouring, under the name of "essence of mirbane," to replace the more expensive benzaldehyde.

Essence of Violets. Whether for flavouring or for perfumes, it is necessary to use only very small quantities of the artificial products. In a concentrated condition, their taste and smell are usually quite different, and even unpleasant. It must be remembered that the natural substances which give the characteristic flavour and perfume to fruit and flowers are present only in minute quantity. This has added considerably to the difficulties of chemists in attempting their synthesis and manufacture on a commercial scale. It has been extremely difficult to procure sufficient for analysis except at impossible prices. Tiemann and Kruger's synthesis of ionone, the perfume of violets, may be cited as an instance. The odour of dried orris or iris root is very similar to that of violets, and as these chemists were unable to procure sufficient violet essence for their experiments, they were forced to work with extract of orris root, assuming the odoriferous principle to be the same in both cases. In the course of their work they isolated a substance, *irone*, from oil of orris, and in attempting to synthesise this body they eventually obtained a substance (*ionone*) very similar to, if not idenical with, the body they were in search of.

Ionone is sold as a 10 per cent. solution in alcohol, but its odour in concentrated condition is quite unlike the odour of violets it possesses when diluted. One part of this solution will produce 100 times its weight of triple extract when diluted with spirit.

Natural and Artifical Products Contrasted. It is not, however, advisable to employ ionone merely diluted down with spirit in this manner. Somehow or other, the odours of these chemical products, even when they are identical with the natural substances, are harsher and less refined. This is probably due to the presence of traces of other substances, and much may be done to improve the artificial products by suitable blending. For this purpose we may use mixtures of artificial substances, or mix them with the natural products; thus, in preparing extracts or scented soaps, the odour of ionone is much improved by the addition of a small quantity of oil of orris.

Many flavouring matters are poisonous in large quantities. A case recently occurred (March, 1906) in a biscuit factory, where one of the operatives drank a quantity of "essence of mirbane," intended for flavouring dough, with fatal results.

Other Synthetic Products. Some of the more important synthetic products are:

Oil of cassia or cinnamon. Cinnamic aldehyde, $C_6H_5 . CH : CH . CHO$, closely related to benzaldehyde or oil of almonds.

Oil of cloves. Engenol, a derivative of phenol.

Oil of wintergreen. Methyl salicylate, $C_6H_4(OH)COOCH_3$, obtained from salicylic acid, and indirectly from phenol.

Oil of garlic. Allyl sulphide $(C_3H_5)_2 . S$.

Oil of mustard. Allyl isothiocyanate $CS : N . C_3H_5$.

Niobe oil. Methyl benzoate, $C_6H_5 . COOCH_3$.

Bergamiol or artificial oil of bergamot. Linalyl acetate.

Vanillin is the active flavouring constituent of vanilla and is prepared synthetically from metamidobenzaldehyde.

The artificial product is often adulterated with acetanilide.

Coumarin is the odoriferous principle of the tonka bean, woodruff and other plants, and is contained in the perfume known as "foin coupé," or New Mown Hay. It was synthesised by Perkin from salicyl aldehyde.

A Perfume from Pepper. Heliotropin or piperonal, a substance having the odour of heliotrope, was originally prepared from piperine, the alkaloid extracted from pepper. It is now made commercially from safrol and is obtained in the form of white crystals. The perfume deteriorates unless the substance is stored in a cool, dark place. The heliotrope perfumes of commerce are made by blending heliotrope with vanillin or coumarin, the cheaper ones with acetanilide. While, in 1880, the price of heliotrope was £70 per lb. it is now 14s., so that the price has been enormously reduced. The same may be said of most other synthetic products: thus, vanillin cost £36 per lb. in 1880, while the present price is £1 12s. But in many cases, as with the essence of violets, the price is not likely to suffer much reduction until the patent expires. Hawthorn (aubépine), or odour of may blossom, is the substance known to chemists as anisic aldehyde and is obtained from phenol. It oxidises in air, so that it should be stored in well-filled bottles.

Artificial Musks. These are substances resembling but probably not identical with the natural product. They are usually prepared according to Baur's patents from toluene. This substance is made to react with butane by means of aluminium chloride and a portion of the distillate nitrated. It forms yellowish-white needles.

Artificial Neroli. Artificial neroli, or nerolin, is the methyl ether of β-naphthol. Bromelia, the odour of which is said to resemble pineapples, is the corresponding ethyl ether. By suitable blending, perfumes resembling lilac, hyacinth, lemon, roses, etc., may be obtained. We should also notice the series of esters of fatty acids having the taste and odour of fruit—for instance, ethyl butyrate, or essence of pineapple, ethyl pelargonate, or quince oil, amyl acetate, or pear essence, amyl valerate, or apple oil, etc.

Synthetic Remedies. These are chemical substances used in medicine, the majority of which are not met with in nature.

FEVER AND HEADACHE REMEDIES

Antipyrine (analgesine), or phenazone. This substance was originally introduced as a febrifuge (used medicinally in cases of fever), but is also employed as an anodyne (to relieve pain). It is known chemically as *phenyl-dimethyl-isopyrazolone* and is obtained by the action of aceto-acetic ether on methyl-phenyl-hydrazine and crystallises in white tables or plates. The salicylate of antipyrine, or "salipyrine," is used for similar purposes. "Hypnal" is a compound of chloral and antipyrine.

Acetanilide, or antifebrin, already referred to under Perfumes, is obtained by boiling aniline [see Coal-tar Colours] and glacial acetic acid. It is represented by the formula $C_6H_5 . NH(C_2H_3O)$, and forms white prism-like crystals. Like antipyrine it is used as a febrifuge. "Antisepsin" is para-brom-acetanilide. Methyl-acetanilide is a specific against headache and known as "exalgin." It is also employed as an anti-rheumatic. Benzanilide, $C_6H_5 . CO . NH . C_6H_5$, is used as an antipyretic for children.

Phenacetin, or para-acet-phenethidine, is another antipyretic and anti-neuralgic, said to be free from objectionable after effects when administered medicinally. In a chemical sense it is related to aniline and may be regarded as a derivative of acetanilide. Its formula is represented constitutionally as follows: $C_6H_4(O . C_2H_5) . NH(C_2H_3O)$. It will be seen that it differs from acetanilide by the introduction of the ethoxy group, $O . C_2H_5$.

Metacetin, a substance having a similar therapeutic action to phenacetin is also chemically related to the latter. It is para-acet-anisidine.

DRUGS TO INDUCE SLEEP

Hypnone, is acetophenone, $C_6H_5 . CO . CH_3$, and is prepared from benzene and acetyl chloride. It is used medicinally as a soporific (sleep producing).

Sulphonal, another soporific, as its name implies, contains sulphur. It is obtained by heating a mixture of acetone and mercaptan with hydrochloric acid. The allied substances trional and tetronal are also used as soporifics.

Numerous other synthetic remedies, mostly the products of German laboratories, have been put upon the market, but few ever find general application. Undoubtedly some of those we have cited are of the utmost importance, and no doubt the really valuable ones will come into general use. There are numerous products containing iron, sometimes in combination with albumen, for the purpose of rendering the former easier of assimilation by the human system. These and similar products are not of sufficient importance to detain us. It may be as well to remind the reader that of the anæsthetics alcohol, ether and chloroform, the last two are obtained synthetically from the first.

Saccharin. This is a white crystalline solid substance with an intensely sweet taste which, according to the most recent information, is said to be five hundred and fifty times as sweet as ordinary cane sugar. That first produced was impure and not more than half as sweet. So accustomed are people to associating sugar with a sweet taste that saccharin is often regarded as a sort of concentrated sugar. This, however, is not the case, as there is no sort of chemical relationship between them. Whereas cane sugar is built up of carbon hydrogen and oxygen only, saccharin contains, in addition, nitrogen and sulphur. The raw material used in its manufacture is toluene, a hydrocarbon related to benzene, and one of the constituents of coal tar. The steps by which it is built up may be followed by placing the raw material, intermediate substances, and final product in order, as follows:

(1)	$C_6H_5 . CH_3$	Toluene
(2)	$C_6H_4 \begin{cases} CH_3 \\ SO_3H \end{cases}$	o– Toluene sulphonic acid
(3)	$C_6H_4 \begin{cases} CO_2H \\ SO_3H \end{cases}$	o –Sulpho-benzoic acid
(4)	$C_6H_4 \begin{cases} COCl \\ SO_2Cl \end{cases}$	Dichloride of o-sulpho-benzoic acid
(5)	$C_6H_4 \begin{cases} CO_2H \\ SO_2NH_2 \end{cases}$	o—Sulphamido - benzoic acid
(6)	$C_6H_4 \left\{ \begin{matrix} CO \\ SO_2 \end{matrix} \right\} NH$	Saccharin.

Saccharin is of an acid nature and can be neutralised with soda. The sodium salt crystallises with two molecules of water, and has the advantage that it is much more readily soluble in water than saccharin itself. It is the chief constituent of the easily-soluble saccharins on the market.

CELLULOID

This product is made from paper or other forms of pure cellulose, by converting them into pyroxylin (guncotton or collodion-cotton), by treating with a mixture of sulphuric and nitric acids. The product, when washed and dried, may be added to melted camphor, and the two moulded together by strong pressure in a hot press, or otherwise closely incorporated, and finally dried and moulded: or the pyroxylin may be dissolved in a mixture of ether and alcohol, in which form it is known as *collodion solution*. If spread out as a varnish and the solvent evaporated, the residual transparent film is known as collodion or celluloid film, and, as we all know, is largely used in photography, for the cinematograph, and for many other purposes where a transparent film is required. There are many modifications and changes in methods of treatment, which space will not permit us to deal with in detail. [For collodion silk see Artificial Silks.]

Celluloid was first made by Hyatt, of Newark, United States of America, who used both the above-mentioned processes. Now a combination of the two processes is more often employed.

"Celluloid may be readily coloured by means of various pigments used either in solution or in suspension and added to the mixture of pyroxylin and camphor before it is subjected to pressure. 'Marbled' celluloid is made by pressing plates of the differently coloured material together. Imitation tortoiseshell, used largely for the manufacture of combs, etc., is made by squeezing together plates of transparent yellow celluloid with similar plates coloured with various shades of brown, etc.

"Celluloid is highly inflammable, but non-explosive even under pressure; hence, it may be worked under the hammer or between rollers without risk. It softens in boiling water, and may then be readily moulded or pressed into various forms. Its specific gravity varies slightly with its composition and the degree of pressure to which it has been subjected; it is usually about 1·35." For further details of the chemical details of manipulation, see Thorpe's "Dictionary of Applied Chemistry," from which the above quotation has been taken.

Great art is now displayed in the manufacture of innumerable articles familiar to us all through their world-wide application. It successfully imitates ivory, horn, bone, tortoiseshell, mother-of-pearl, and many other natural products, besides replacing ebonite, vulcanite, china, glass, etc. Celluloid can generally be recognised by the smell of camphor which it emits when briskly rubbed. But even this is reduced to a minimum, if not entirely eradicated, by skilful manipulation. Its chief drawback is its inflammability, which is now, however, largely reduced. Hundreds of different articles are made from celluloid or "Xylonite," the name given to it by the British Xylonite Company, Ltd.

MATCHES

A match is defined in Thorpe's "Dictionary of Applied Chemistry" as "an instantaneous fire producer, consisting of a short stem, rod, or tube, tipped at one or both ends with a composition or paste, inflammable by friction."

The lucifer match has come into existence within the last 70 or 80 years. Prior to this the production of fire by the kindling of suitable combustible materials was promoted by friction, at one time by the rubbing together of two stones, or later by flint and steel. The latter is familiar to many of us in the old flint-lock guns of our forefathers to be seen in the old armouries. The rubbing of two pieces of wood together is the method still employed by the North American Indian and the Polynesians, who obtain fire by rapidly rotating a pointed rod of dry, soft wood, called a fire-drill, against a block of harder wood.

It is impossible to deal with the history of the different substances employed and the different methods in vogue from the time of the "phosphoric taper" up to the present, or to refer to the various forms of vestas and cigar lighters. A mass of patents have been taken out by those connected with the industry, an account of which will be found in Thorpe's "Dictionary of Applied Chemistry."

The operations performed in the manufacture of wooden matches consist as follows:

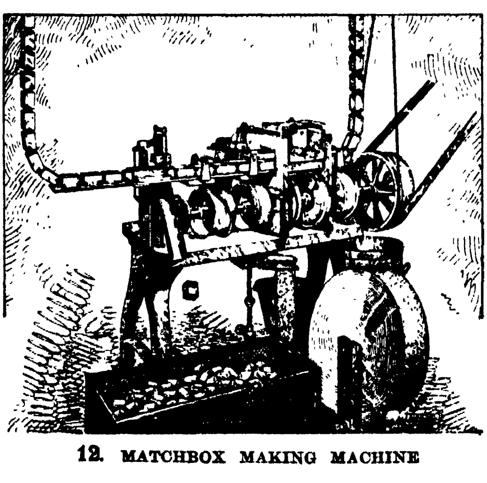
1, Barking; 2, cross-cutting; 3, steaming; 4, splint-cutting; 5, drying the splints; 6, filling the dipping frames; 7, paraffining; 8, dipping; 9, drying the dipped splints; 10, racking out; 11, halving, or cross-cutting; 12, boxing.

All of these processes were, and still are, involved in hand-made matches. Machines, however, are now almost universally employed.

Match-making Machinery. The blocks of wood, which come from Canada, are all cut to a uniform thickness equal to the length of the match and placed in position by hand, with the grain in the proper direction, on two endless leather travelling bands, between friction rollers to ensure their being fed towards the cutters at an even pressure. The dies or cutters are small steel bars of rectangular cross-section, having a hole the size of the match to be cut drilled in them at one end. The dies are placed together side by side in rows of 48 or more, the whole being moved up and down by the action of a cam. A whole row of match splints or sticks are cut on the downward stroke. A plate carrying a row of pins then ascends under the bottoms of the match-sticks just cut, and drives them into counter-sunk holes in an endless chain of metal plates and without breaking them. This chain carries them forward with their points downward, where they are first of all dipped to the depth of an eighth of an inch into a bath of paraffin wax, the surface of which is kept at a definite level by an ingenious contrivance. The dipped matches, after travelling forward until the paraffin has had time to set, come in contact with a roller covered with the igniting composition, revolving at the same pace at which the matches are travelling, to ensure that the heads are not one-sided. The matches, after travelling round the machine in the endless chain, which runs over a number of drums, are punched out from this by a row of pins, corresponding in number and position to the holes in the chain, into empty boxes passing along an endless chain band ready to receive them, which, when full, passes on to a revolving table, where the covers are put on by hand, after which they are made up into packets of one dozen and parcels of six or twelve dozen. Very few girls are required for the handwork necessary on the output of a machine which in one day often equals 144,000 boxes, each box containing about 60 matches.

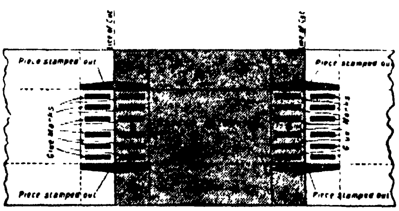
Machines are now constructed to do away with hand packing, the whole of the handling from start to finish being done by machinery.

Box Making. "Chip" boxes, in which the chips are fastened together by pasted paper, are sometimes made by hand, but generally by machine. The strawboard boxes are made automatically from strips or reels of strawboard. The shape into which the material is cut and the places in which it is scored are shown in **12**. The strip is first scored by sharp wheels, so that it bends easily, and is then glued at regular intervals by means of an arm worked by a cam. The arm has twelve projections upon it, and it works up and down, in and out of a vessel containing melted glue, touching the cardboard at the top of its upward stroke, thus making a series of glue patches as shown in **12**, which will make the description clear. The strip is then fed forward, and holes are punched in it at regular intervals beside the glue-marks, as shown. These pieces are the only waste there is. After being glued and punched, the strip is automatically cut into suitable lengths, the line of cut running between two sets of glue-marks, as shown, and the piece cut off is then caught by a descending die, the edges A being turned upwards and inwards, and the edges B being pressed upwards and against them, and the box thus formed is forced into a metal former, a number of which are joined together in a continually revolving chain or band in the machine [**13**], in which it travels for one revolution of the band. By the time the revolution is complete the box is dry, and it is then automatically released from the "former," to fall into baskets or crates. Each of these machines will turn out about 80 boxes per minute.



12. MATCHBOX MAKING MACHINE

The machine for making the strawboard covers is fed from a reel of cardboard, which on its passage is glued, folded over, and so converted into a tube. The tube then traverses the length of the machine twice, and during its passage it dries, and is turned over so as to get the join in a suitable place for future operations. The tube then passes between two printing rolls, which print the requisite design on each face. It is then cut off to proper lengths, and the last process is to bring the edge of each box-cover against a wheel dipping in melted glue, and then to throw white sand against the glue when it is still wet to form the friction surface. Such machines turn out from 800 covers per minute.



13. MATCHBOX BEFORE FOLDING UP

Wax Vestas. In making wax vestas, the cotton twist which forms the wicks is drawn from a large slowly revolving cylinder, through a bath containing a mixture of stearin and gum, through dies, and then on to another drum. They are passed slowly backwards and forwards from drum to drum until the taper is of the requisite thickness. The taper is then fed from the drums into a machine similar to that described for wooden matches, which cuts it into the length required, the chief difference being the manner in which the wax tapers or vestas are held, they being gripped by springs which hold them firmly for the operation of dipping in the igniting composition without pinching or marking them. The operation of dipping in paraffin wax is, of course, not necessary in the case of wax vestas.

Composition Room. In this room the igniting composition is made, in which the match is dipped in the manner already described. These compositions are made to formulæ known only to the makers. Messrs. Bryant & May do not use white or yellow phosphorus in the manufacture of their strike-anywhere matches, but a substance without smell and harmless to the operators. This is mixed with glue, chlorate of potash, certain other materials and colouring matter, the ingredients being weighed and carefully milled to ensure a thorough amalgamation.

SIMILAR FIGURES

Equiangular Triangles. Theorems Connected with Right-angled Triangles. Definition of Projection. Problems in Proportion

By HERBERT J. ALLPORT, M.A.

Proposition 55. Theorem

If one side of a triangle is divided, internally or externally, into segments proportional to the other sides of the triangle, the line joining the point of section to the opposite angle bisects that angle internally or externally.

With the figures of Proposition 54, let BC be divided at D, so that

BD : DC : : BA : AC.

It is required to prove that AD bisects the ∠A, internally or externally.

Proof. With the same construction as before, since AD is ∥ to one side of the ΔBCE,

BD DC : : BA AE (*Prop.* 52).

But BD DC : : BA AC (*Hyp.*).

∴ BA AE : : BA AC.

∴ AE = AC.

= ∠ACE

= alternate ∠DAC.

And ∠FAD = ∠AEC.

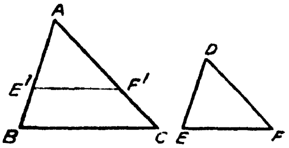
∴ ∠FAD = ∠DAC,

i.e., ∠A is bisected.

Proposition 56. Theorem

If two triangles are equiangular to one another, their corresponding sides are proportional.

Let ABC, DEF be two Δs in which ∠A = ∠D, ∠B = ∠E, and ∠C = ∠F.



It is required to prove that the three ratios BC and ... equal.

Proof. Place the ΔDEF on the ΔABC so that D falls on A and DE falls along AB. Then, since ∠D = ∠A, DF will fall along AC. Let E′, F′ be the new positions of E, F. Then,

∠E′ = ∠B.

∴ E′F′ is ∥ to BC.

∴ AB : AE′ : : AC : AF′,

i.e., AB : DE : : AC : DF.

Similarly, by placing ΔDEF on ΔABC so that E falls on B, and ED, EF fall on BA, BC, we can prove that

AB : DE : : BC : EF.

Hence,

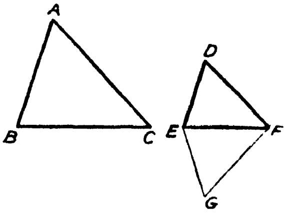
BC : EF = CA : FD = AB : DE.

Proposition 57. Theorem

If two triangles have their sides proportional, when taken in order, the triangles are equiangular, those angles being equal which are opposite to corresponding sides.

Let ABC, DEF be two Δs, in which

BC : EF
= CA : FD
= AB : DE.



It is required to prove that Δs ABC, DEF are equiangular.

Proof. At E, in EF, make ∠FEG = ∠B. At F, make ∠EFG = ∠C. Then

∠G = ∠A (*Prop.* 14).

∴ AB : GE : : BC : EF (*Prop.* 56).

But AB : DE : : BC : EF (*Hyp.*).

∴ GE = DE.

Similarly, it may be proved that GF = DF.

∴ ΔDEF = ΔGEF (*Prop.* 7).

But ΔGEF is equiangular to ΔABC.

∴ Δs ABC, DEF are equiangular.

Definition. Two rectilineal figures are said to be *similar* when the angles of the one, taken in order, are equal respectively to the angles of the other, taken in order, and when the ratio of each side of the one to the corresponding side of the other is the same.

Thus, *similar* figures are figures which have the *same shape*. Note that *two* conditions are necessary for figures to be similar. In the case of triangles, however, we see from Props. 56 and 57 that the one condition involves the other; *i.e.*, if Δs are equiangular they are similar.

Proposition 58. Theorem

If two triangles have one angle of the one equal to one angle of the other, and the sides about these angles proportional, the triangles are similar.

In the figures of Proposition 56 above, let ABC, DEF be two Δs in which ∠A = ∠D and AB : AC : : DE : DF.

It is required to prove the Δs are similar.

Proof. Place the ΔDEF on the ΔABC so that D falls on A, DE along AB, and DF along AC. Let E′, F′, be the new positions of E, F. Then, since

AB : AC : : DE : DF,

∴ AB : DE : : AC : DF,

i.e., AB : AE′ : : AC : AF′.

∴ E′F′ is ∥ to BC (*Prop.* 53).

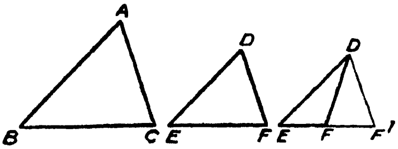
∴ ∠AE′F′ = ∠B, and ∠AF′E′ = ∠C (*Prop.* 12); so that ΔAE′F′; *i.e.*, ΔDEF is equiangular to ΔABC.

∴ Δs ABC, DEF are similar.

Proposition 59. Theorem

If the ratios of two sides of one triangle to two sides of another triangle be equal, and if the angles opposite to one pair of these sides be equal, *then the angles opposite to the other pair are either equal or supplementary.*

Let ABC, DEF be two Δs in which $AB : AC :: DE : DF$ and $\angle B = \angle E$.



It is required to prove that either $\angle C = \angle F$, or $\angle C + \angle F = 2$ right $\angle$s.

Proof. (i.) If $\angle A = \angle D$, then $\angle C = \angle F$ and the Δs are equiangular.

(ii.) If $\angle A$ is not $= \angle D$, make $\angle EDF' = \angle A$.

Then Δs ABC, DEF' are equiangular.

$\therefore AB : DE :: AC : DF'$ (*Prop.* 56).

But $AB : DE :: AC : DF$ (*Hyp.*).

$\therefore DF = DF'$.

$\therefore \angle DF'F = \angle DFF'$.

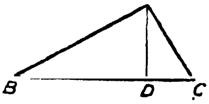
But $\angle$s DFE, DFF' are supplementary.

$\therefore \angle$s DFE, DF'F are supplementary,

i.e., $\angle$s DFE, ACB are supplementary.

Proposition 60. Theorem

In a right-angled triangle, if a perpendicular drawn from the right angle to the hypotenuse, the triangles on each side of it are similar to the given triangle and to one another.



Let ABC be a Δ in which $\angle A$ is a right $\angle$. Draw AD $\perp$ to BC.

It is required to prove that Δs ABD, ACD are similar to ΔABC and to one another.

Proof. In Δs ABC, ABD, the right $\angle BAC$ = the right $\angle ADB$; the $\angle B$ is common to both Δs.

$\therefore$ Δs are equiangular, and therefore similar.

In the same way it can be shown that Δs ABC, ACD are similar.

Then, since Δs ABD, ACD are each equiangular to ΔABC, they are equiangular to one another, and therefore similar to one another.

Corollary. Since Δs ABD, ABC are similar,

$\therefore DB : BA :: AB : BC$.

$\therefore AB^2 = BD . BC$.

Similarly, from Δs ACD, ABC we get

$AC^2 = CD . CB$,

and from Δs ABD, ACD

$AD^2 = BD . DC$.

Thus, *the square on any one of the lines terminating at A is equal to the rectangle contained by the two segments which terminate at the other extremity of the line.*

Projection. The foot of the perpendicular drawn from a point to a line is called the *projection* of the point on the line.

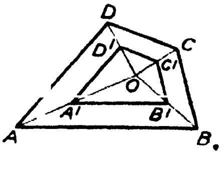
If P, Q are the projections of two points A, B on the line CD, the segment PQ is called the projection of AB on CD.

Thus, the first two cases of the above corollary may be worded as follows: *The square on either side of a right-angled triangle is equal to the rectangle contained by the hypotenuse and the projection of that side on the hypotenuse.*

Problems. By the aid of the foregoing propositions it is easy to prove the constructions given in Geometrical Drawing [page 472] for the finding of a fourth, third, and mean proportional to given lines. The construction for dividing a line, internally or externally, in a given ratio is very similar, and should present no difficulty.

Proposition 61. Theorem

If two rectilinear figures are similar, they can be placed so that the lines joining corresponding ver rent.



Let ABCD and B'C'D' be similar figures.

Then, since $\angle B = \angle B'$ they can be placed so that AB, BC are respectively $\parallel$ to A'B', B'C'.

Since the figures are equiangular, it follows that CD is $\parallel$ to C'D' and DA is $\parallel$ to D'A'.

It is then required to prove that the lines AA', BB' CC', DD' meet in the same point.

Proof. Let AA', BB

Then, since A'B' is

$OB' : OB \quad A'B' \quad AB$ (*Prop.* 52).

But $A'B' : AB \qquad BC$ (*Hyp.*).

$\therefore OB' : OB \ldots \; BC$;

i.e., $OB' : B'C' :: OB . BC$.

And $\angle OB'C' = \angle OBC$, since B'C' is $\parallel$ to BC.

$\therefore$ Δs OB'C', OBC are similar (*Prop.* 58).

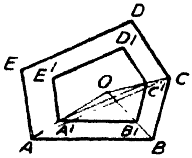
$\therefore \angle B'OC' = \angle BOC$.

$\therefore$ OC', OC are in the same straight line; *i.e.,* CC' passes through O.

Similarly, DD' passes through O.

Proposition 62. Theorem

If two rectilineal figures are similar, their corresponding sides and diagonals are proportional



Let ABCDE, A'B'C'D'E' be similar rectilineal figures.

It is required to prove that

$AB : A'B' = AC : A'C'$
$= AD : A'D'$, etc.

Proof. Let the figures be placed so that AA', BB', CC', etc., meet in O (*Prop.* 61).

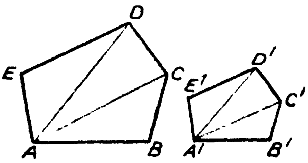
Then, $OA : OA' = OC : OC'$ (since each ratio $= OB : OB'$).

$\therefore$ Δs OAC, OA'C' are similar (*Prop.* 58).

$\therefore AC : A'C' = OA : OA'$
$= AB : A'B'$.

Similarly, the ratio $AD : A'D'$, etc., can be proved $= AB : A'B'$.

Corollary. It follows that: *If two rectilineal figures are similar, the triangle formed by joining any three vertices of the one is similar to the triangle formed by joining the corresponding vertices of the other.*



For $AC : A'C' = CD : C'D' = DA : D'A'$, since each ratio is equal to $AB : A'B'$.

$\therefore$ the Δs ACD, A'C'D' are similar.

CUTLERY

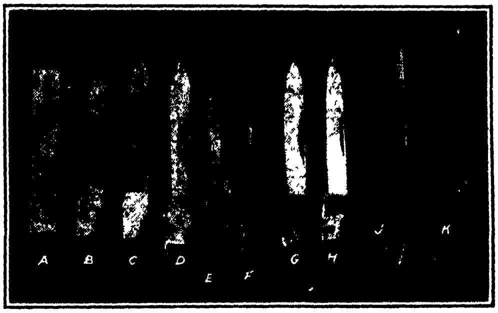
The Manufacture of Penknives, Table Cutlery, Scissors and Razors. Forging, Assembling, Tempering, Hafting and Finishing

By J. H. VINNICOMBE

THE genius of the inventor has not yet superseded the genius of the cutler. Every day we see machinery a rival to the brain and deft fingers of the mechanic; and modern mechanism has not been without its influence in the manufacture of cutlery. But the Sheffield cutler who to-day makes penknives is no more disturbed by thoughts of a machine excelling the cunning of his hands than was his predecessor of two centuries ago.

The ambition of every youth is to possess a knife. As briefly and as plainly as possible we will endeavour to teach him how his knife is made. It should be stated that in the cutlery trade there is a distinction between the "penknife" and the "pocket-knife," although purchasers frequently regard them as different descriptions of the same article. A penknife, as the name suggests, is an instrument which was originally made for cutting "quill" pens, an operation necessitating a fine-cutting edge. A pocket-knife is different, and is constructed to meet those tougher objects which blunt the blade of the more delicate and finely-constructed instrument.

Making a Penknife. The knife which we are about to make with the aid of the apprentice sitting at the bench is one of the simplest patterns, with a single blade. The illustration [1] affords some indication of the processes associated with the making of the blade from the rough piece of steel to its polished state, before it reaches the penknife maker. In front of us are the steel blades, the spring, which will go at the back of the knife, two metal scales, which will enclose the blade, and two pieces of ivory for the covering, or outside scales. Various materials are used for the last-mentioned purpose, such as pearl, ivory, tortoiseshell, stag-horn, and sometimes gold, agate, silver or aluminium, in addition to others. It must be understood that many hands are engaged in the making of a knife; the cutler is the man who fits together the different articles supplied to him. For every knife made there are patterns of the parts, and those which we have to follow we keep well in front of us for the purpose of guidance and for measurement.



1. PARTS OF A PENKNIFE

a Piece of cast steel from which blade is forged *b*. Mood of blade—first stage *c*. Mood of blade tang, second stage *d*. Smithed blade ready for hardening, third stage *e*. Hardened blade *f*. Tempered blade *g*. Rough ground blade with glazed tang and shoulder *h*. Polished blade—finished *j*. Filed out spring for knife *k*. Hardened and tempered spring for knife

We take the metal scales. At one end of each is what may be described as a *shoulder-piece*. It is fixed to the scale, and will form an important part in the knife because it will hold the blade. It is known as the *bolster*. Its edges are a little ragged when the scales are received by the cutler, and the first process is to "trim the bolster edges," clipping them with shears. Having fixed two temporary pins in the metal scales to keep them together, the next operation is to file the scales according to the pattern or shape of the knife intended to be made. To do this we place a scale on each side of the steel pattern, put them into a vice, and file away the edges until the proper size and shape are attained. There is not much waste, as in giving out the pieces the manager is careful to see that they are as near the size of the pattern as possible. Having made the scales the required size, we take a drill and bore the rivet-holes, not much larger than the eyes of some needles. Through these will pass the small pins for holding the ivory covering, which we match to the scales and fasten them together. Now, instead of the four pieces of material being separate, they are joined so that we have the two coverings for each side of the blade—the ivory being outside, with the layer of brass as the inside lining. We next bore two holes through these two parts, and into these the pins will be inserted to hold the spring, which will form the back of the knife.

Preparing the Parts. Attention is next devoted to the ivory covering, which we find is not the exact shape of the metal lining, so it is filed down until the two are in perfect agreement according to the pattern. The steel spring, which will play such an important part in the movement of the blade, is, perhaps, not quite flat, so this is hammered a little until it is level. We next mark on the spring the two places for the two holes to correspond with those on the outer covering. The necessity for accuracy will be apparent here, otherwise the parts will not fit. The holes through the ivory and metal scales have been made by the use of a hand drill; to penetrate the steel spring it is necessary to go to a drilling machine. The operation is soon completed, and we return to the bench and file the inside of the spring in order to make it work smoothly, and cut it by means of a proper tool to the proper length. It may be presumed that the intention is to make a dozen penknives, because the boy will usually work on this number, and not go straight through and complete one knife before he begins another. Now we bunch twelve springs together and attach them to a wire in order to harden and temper them. We first make them hot in a hearth fire, next plunge them into water, and then, having dried them, cover them with oil, which is made to blaze. This process at an end, the springs are brought again to the bench, and one is selected which is intended for our knife, and this is made perfectly straight by the use of a hammer. Then we place it on an emery wheel, which, revolving at a great speed, does the glazing and imparts that bright appearance to the inside of the spring which may be observed on opening the blades of a knife.

Hafting the Penknife. After all this preparation an important step is taken in the building up of the knife by placing the spring in its proper position between the scales. We have already referred to the drilling of two holes for this purpose, and very little time is required to pass German wire through the ivory, the metal scales, and the spring. The parts are thus pinned together. We now see the handle of the knife before us, and the next question naturally relates to the blade. Everyone will have observed the bottom portion of the blade by which it is held to the handle. This is known as the *tang*, while that part at the top of the handle which holds the blade and is fixed to the metal scale is known as the *bolster*. We have a pattern for the blade, from which is learnt the proper place for the hole in order to pin it to the handle. Having roughly ground the blade we make another visit to the drilling machine and bore a hole through the tang; and now follows an important operation—it is known as *squaring the blade joint*. Taking our blade, we file the joint at the bottom, making it agree exactly with the pattern in order that it may fit into the bolster. Having burnished the tang, and thus removed any roughness on the sides, the blade is ready to be fixed to the bolster. We have already made the hole, and having put the blade into position, we run a piece of iron wire through it, and the blade is riveted to the handle. The appearance of the rivet on the bolster would be regarded as a disfigurement, so it is filed down, and the top spread until it becomes a part of the bolster, and cannot be seen by the eye.

Finishing Processes. We have now travelled a good way towards making the penknife, and having got the blade into the handle, we move it in order to see whether it is in true position. A little filing may be necessary to make it work accurately. This is known as *jointing the blade*. So far as the construction of our penknife is concerned, it is now practically completed; but there are a number of processes yet to be followed before it has that finished appearance which appeals to the eye. We file the back of the spring, and afterwards put the back of the knife on the emery wheel, and the outside of the spring is roughly glazed. Then we put it on a finer wheel, and the operation of *fine glazing* is performed. The exterior of the spring is now getting like a mirror with the brightness that is being imparted to it. The knife is next fixed in a wooden clasp, and placed in a vice, so that the ivory handle may be filed and made smooth prior to the polishing; then we file the bolster, afterwards glazing it as we did the spring back, first giving it the rough glaze. Finishing touches are next given to the ivory by rough buffing on the wheel; all scratches and marks are in this way removed. Then we give the fine glaze to the bolster, and this is followed by the fine buffing of the ivory. Various wheels are used for these different processes in order to get the desired results. Then the knife is placed in the vice, and the back of the spring receives its final shine by being burnished with a steel burnisher. The next process is to place the bolster on a polishing wheel, and by the use of the proper material the requisite brightness is given to it. We then wipe the knife to make it clean, and our task is completed. Great care is exercised in order that the handle shall not be soiled, and the ivory is covered with paper. After having been whetted, or sharpened, the oil and dirt will be wiped off to prevent rust.

2. DOUBLE-HAND FORGING CARVING KNIVES

3. MACHINE FORGING TABLE KNIVES

Large Pocket-Knives. The large pocket-knives, as already indicated, are for rougher work than that for which the penknife is designed, and in their construction the delicate treatment to which reference has been made is not required. In the pocket-knife shop the boy will not be set at first to build up a knife. He will be required to do different tasks necessary to the parts; it may be to straighten the springs, or drill the holes; but by degrees he learns how to construct a knife. It is, however, in the penknife that the genius of the cutler is revealed. Unfortunately, the demand for cheap articles has led to inferior articles of cutlery being offered for sale. This is really bad for the cutler and the customer.

Table Knives and Forks. Without an insight into the manufacture of cutlery it is difficult to imagine the number of processes associated with the making of a knife. It has been computed that in the putting together and finishing-off of a plain, four-bladed penknife, after all the different parts have been made ready for the cutler, 154 operations have to be gone through. It is now intended to describe the making of table cutlery, in which there are different trades associated. We may cite three as the chief—namely, forging, grinding, and hafting, and at once proceed to deal with these, and follow the operations in the manufacture of a table knife.

4. HARDENING AND TEMPERING TABLE KNIVES

Forging Table Knives. We first proceed to the forging shop [2], and there observe the hearth fire, anvil, striking tools, and rods of steel placed against the walls. Needless to say, the quality of the steel is of the first importance. The brightness of the blade and the artistic character of the ornamentation of the knife will contribute little to the quality of the cutlery if the steel be poor. The steel reaches the forging shop in long rods, which have been rolled to various shapes and sizes according to the purposes for which they will be required.

5. GRINDING AND GLAZING CARVING KNIVES

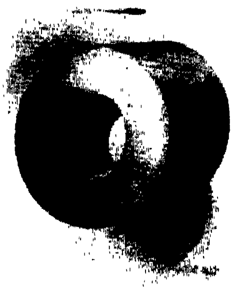
Proceeding to make a table knife, the forger will take a bar of steel and place the end into the hearth fire. We watch him work the bellows with his left hand, while at times he withdraws the steel from the hearth. The casual spectator would not appreciate the judgment required in this operation. The skilful forger understands exactly when to withdraw the steel and place it on the anvil. The steel, yielding to successive strokes, gradually assumes the rough shape of the blade, or *mood*, as it is called in the trade. This is now cut off from the bar of steel at the proper length according to the size of the blade required, the forger having a measure on his anvil as a gauge. The blade is then welded to a piece of iron, from which the bolster and the tang will be produced. In table cutlery the bolster may be described as the raised part at the bottom of the blade near the handle, while the tang is drawn out, and is that portion which is fitted into the handle. It is made by a few blows given to the iron as it rests on the anvil, the bolster being formed by hammering the red-hot iron in a *print*, which gives the shape desired. The blade is then heated a second time. On being withdrawn it is hammered more into shape, and the "smithing" process takes place, the hammering giving toughness and strength to the blade. The name and trade mark of the firm are then stamped upon it. Figure 3 shows the process of machine forging, the machine being a power-hammer.

Hardening and Tempering. Now follow the important operations of hardening and tempering the steel [4]. The blade is raised to a cherry-red heat, and on being taken from the fire it is plunged into water. It is now hard, but as brittle as glass, and would break if it were allowed to fall to the ground. Tempering is required, and this process demands no little experience and judgment on the part of the forger. After being made red hot and plunged into the water as already described, the blade has a grey-white colour. The workman now puts it into the fire again, and the blade changes first to straw colour, next to mottled brown, and purple, then dark blue, and finally light blue. The different degrees of tempering, which follow rapidly upon one another, have to be closely watched by the forger, who has been taught by years of experience to understand the different qualities of steel and the point at which a blade must be withdrawn from the fire. It may be explained that the stage of tempering depends upon the article, and the use to which it will be applied when finished. For instance, the carving and table knives are taken to the light blue hue; the strong pocket-knife, which will be used for some rough work probably, to the dark blue; a fine penknife to a point between straw colour and brown; and the razor blade, which receives the keenest edge of all cutlery instruments, is withdrawn at the straw colour.

Having withdrawn the blade to be used for the table knife, with its light blue tint, from the hearth, the forger again plunges it into water, and in this way proper flexibility is imparted to it. At some works there is machine as well as hand forging of table blades. When machinery is used, the making of the bolster and the tang and the hardening and tempering are separate processes carried out subsequently.

Grinding and Polishing. The forger has now completed his task, and the blade is ready for the grinder [5]. The grinding wheel, or *hull*, as it is usually called in Sheffield, makes an interesting picture. Speaking is carried on only with difficulty amid the hum of machinery and the noise of blades being applied to quickly-revolving wheels. We see the grinders sitting astride their "horses," and watch the pyrotechnic display as steel and stone come in contact. The grinders are at work on different kinds of stones. First we see the blade applied to the rough stone. This runs in a trough with water up to the surface of the stone, keeping it cool and preventing the heating of the blade, which is placed on a flat stick hollowed out for the bolster. Bending over the stone, the grinder puts sufficient weight on the blade to remove the rough surface. It next receives a finer surface by being placed on the "whitening" stone, which is smoother and harder than that on which the first grinding process took place. The blade is next rough glazed, and then fine glazed upon a wheel dressed with a combination of emery, beeswax, etc. By this process the marks left by the grinding stones are removed. The final polish is produced by "buffing." This is obtained by passing the blade over a wheel covered with thick leather, dressed with superfine flour emery, with the surface thinly covered with beeswax and suet. The last operation being completed, the blade is ready for the hafter, who will fit it with a handle.

Hafting Table Cutlery. In the hafting shop we see fine drills, small wheels, somewhat similar to those which we observed in the penknife department, and delicate files. All these are used either for treating the blade or for preparing the ivory for the handle. The tang is straightened, then the bolster is levelled and filed. The glazing of the back of the blade and bolster follows, after which the bolster is passed over a fine stone wheel and the hollow portion is ground. Subsequently this is fine glazed and polished. Attention is now devoted to the tang, which is also glazed. Then follow various processes associated with the preparation of the ivory handle before the tang is inserted. There is the turning of the head of the handle, the rough and smooth filing of the ivory, called *floting* and *single cutting*, the drilling of the hole into the ivory, a difficult operation requiring much practice in order that the drill shall do its work properly. The handle is then made finer by the use of what is called a *shaving* knife, which takes out all the file marks of the single-cut file, after which it is rough buffed by being passed over a specially prepared wheel, called a *sandbuff*, which revolves rapidly, and next it is fine buffed. The matching of the handle to the blade in order to see that it will fit properly follows. Everything being in order for inserting the tang, resin is taken from a small utensil which is kept on a fire, and with this the tang is "cemented" to the handle. Sometimes the tang will go right through the handle with a rivet at the end. This is called a *through-tang* knife. Others will be pinned at the side, and are called *edge-pinned*. The handle will subsequently undergo another buffing process, after which there will be the "dollying," which means placing the handle against a rapidly revolving wheel made of calico. This operation gives to it a shiny appearance. The back of the blade is then burnished, after which the surface is drawn over a very fine "buff," giving it the final polish. It is then "whetted," wiped, and wrapped up for the customer.



7. EMERY CYLINDER FOR GRINDING RAZORS

Making Forks. In the making of nickel silver table forks, which are now so generally used, machinery plays a great part. This can be easily imagined when it is seen that the fork is formed of one piece of material. The metal having been cut into strips of the necessary width, they are then rolled, one end of the fork being required thinner than the other. From these strips the forks are cut out by a machine, and stamped in steel dies to the particular pattern required. The prongs are next "flied" out, after which they are made to assume a neater appearance by a stamping machine. The fork is then filed and bent into the proper shape, and the article receives the impression of the name of the firm, and the trade mark. Having been filed in the rough, the buffing process is carried out, and in this work women and girls are largely employed, the forks being passed over leather wheels dressed with sand and oil. The forks are now ready for plating, a process carried out in the electroplating department. They are afterwards burnished, and then finished on a calico "dolly" dressed with oil and lime, and subsequently they receive a brighter appearance from a finer "dolly," after which they are wiped and sent to the warehouse.

6. PUTTING SCISSORS TOGETHER

Scissors. The forging operation in the making of scissors is most important, and it is only after years of experience that a man becomes a skilled craftsman. The forger of scissors has a shop which resembles closely that of the knife forger; but their operations are quite dissimilar. The former makes the blades, and also the bows, and, although in a rough state, the scissors are complete, so far as shape is concerned, when they leave his hands. The forger first heats the end of the bar of steel, and having withdrawn it from the fire brings his hammer into action, and shapes the blade, which he severs from the bar, leaving sufficient for the shank and the bow.

He will now "set out" the shank by a few strokes of his hammer, and then, placing it against the point of a small anvil, punch a small hole, which later he will increase in size for the bow. The steel is again heated, and the next operation is hammering out the blade. This is followed by the setting out of the joint, an important part of the work, because the is where the hole for the screw will be bored, and care has to be exercised in making the joint in order that the blades may pair harmoniously. This having been accomplished, there is next the smithing of the blade, which we see gradually assume its proper shape under the strokes of the hammer. Once more the steel is returned to the fire, and the next movement is towards the formation of the bow. We have already referred to the small hole which has been punched; by skilfully hammering the steel on a tool which the forger has on his bench he increases it to the proper size.

Making Large Scissors. So far we have dealt with an ordinary pair of scissors; the larger sizes are treated differently in the forging process. The large bows are not punched in the manner just described. The steel having been heated for the blade, or "mood," it is welded to a piece of iron, which is afterwards drawn out, and later on, after the smithing of the blade, we appreciate the skill of the forger as he curls the iron in the shape of a large bow, and uses his hammer with such dexterity that it is impossible to see where the bow begins or ends. The scissors, in their rough state, and not yet put together, are now taken to a shop for filing. Next they go to be bored, hardened, and tempered, and then to the grinding wheel, where the blades are ground. From the grinder they go to be filed and burnished. The scissors are next taken to the "putter together," as he is known in the trade. He makes the screw that will join the blades. The hole into which the screw is inserted may be described as being of three sizes. It is largest at the top, for the head of the screw, which will be level with the side of the scissor blade. The middle of the hole is smaller, but sufficiently large to allow the screw to work freely, while the size of the hole in the under blade will be only large enough to permit the screw to fit tightly. The scissors-maker or "putter together" has to see that their blades will do their work efficiently. With the use of his hammer he gives the blades the proper curve.

Having fitted the screw, he will take it out and put it carefully into a box, to be used when the blades are finally joined. Each pair of scissors has a distinguishing mark, and the scissors-maker will know the particular screw wanted for each when a large number of blades are subsequently returned to him. When he has made them fit properly, they go again to the grinder, and the blades and shanks are put on a finishing wheel, after which the bows are burnished with a burnishing iron, young women being frequently employed for the latter operation. Now, almost as bright as silver, they are returned to the scissors-maker, who puts them together [6] with the screw that he has already made and satisfies himself that they are perfect.

Razors. The hollow-ground razor has grown into popularity, and in the production of this the grinder plays an important part. Two qualities are claimed for this kind of razor. First, the hollow-grinding gives an edge so thin and so broad that it can be frequently whetted upon an oilstone without requiring to be reground; and secondly, the thinness tends to the lightness of the razor. In the case of the ordinary flat-ground razor, after being whetted a few times, it has to be sent to the grinder again.

The grinder, having received the blades from the forger, proceeds to shape the tang on a dry stone. He also gives the point of the razor its proper shape, making it either round or square. The tangs are then put into the fire, and after having been taken out and allowed to cool, they are given to the file cutter, who makes the indentations on the underside of the blade. This enables a better grip to be obtained by the person who is shaving.

The grinding processes now begin. After the blade has received an edge, the hollow-grinding of the blade lengthwise is proceeded with. It is placed on a stone in which have been cut deep grooves. Next follows the process of cross hollow-grinding from back to edge, and this work is performed on very small stones [7]. After this process [8] there is the glazing and the polishing of the tang.

8. HOLLOW-GRINDING RAZORS

Hafting Razors. Proceeding to enclose the blade in an ivory handle the hafter will receive scales cut to the required length. These he will put to a plate, which is his guide as to pattern. By filing the edges of the ivory, he secures the proper shape, and then, with a fine, single-cut file, he will remove any roughness on the face of the ivory, and afterwards, with a shaving knife, take away the marks that are left by the operation. The ivory will next be buffed on a leather wheel dressed with bathbrick and oil. The scales are now ready to allow the small piece of metal to be inserted in the lower part of the handle, just above the point of the blade when it is closed. This is riveted in, filed, and burnished, after which the blade is riveted with wire at the other end. The hafting is then complete, and the razor is whetted and sharpened on special stones.

The illustrations in this article are from photographs of the works of Messrs. Thomas Turner & Co., and Messrs. Joseph Rodgers & Sons, Sheffield.

GLOVE MANUFACTURE

Centres of Glove-making. Varieties of Gloves. Tools and Materials. Preparing the Leather. Cutting Out. Sewing. Finishing

Group 20

LEATHER

19

Continued from page 5342

By W. S. MURPHY

THE chief centres of glove-making in England are London, Worcester, Leominster, Woodstock, Yeovil, and Ludlow. Up till near the close of the nineteenth century the factory system took little hold on leather glove manufacture, and at Woodstock and Worcester the hand worker still keeps a firm grip of the trade. Glove-making by hand is a home industry. The master glover of Worcester, for instance, gives out the leather and the orders to the workers, who take them home, it may be in a village five or six miles away, and there, father, mother, or children, make the gloves. When finished, the work is brought back to Worcester. At Woodstock, where a special kind of doeskin glove is made, the system is different. But glove-making there also a home industry, and one may see the tawed leather hanging in the back gardens of the workers.

21. LEATHER WASHING

Varieties of Gloves. Dress kid gloves are the most common form of glove. These are made in many colours and of qualities ranging in retail value from 1s. 6d. per pair up to 7s. 6d., or over. The best qualities are plain, coming only to the wrist, and consist of real kid. Lower qualities are made to resemble kid, the finer class from lambskins, and the rest from sheepskins.

The long-armed gloves which came over from France in Charles II.'s reign have flickered in and out of fashion ever since, and are made in considerable quantities at all times. But the length varies greatly. In general, it may be said that there are three lengths—above the wrist, up to the elbow, and midway up the biceps, the extension being generally, though not always, regulated by the shortness of the dress sleeve.

Gauntlets are a form of glove almost constantly in demand as riding gloves by ladies. The cuff springs out wide at the wrist, and is stiffened either by padding or cane facings. They are made in all kinds of leathers, but more commonly in the heavier classes. Suède gloves are made of skins with the flesh side outward, giving a soft surface.

Doeskin gloves are probably the most durable of fine gloves, very pleasant to the hands, and yet capable of standing rough wear. Many golfers, riders, hunters, and other sports lovers of both sexes, find them very useful. The skin of the deer, from which real doeskins are made, is at once soft and unstretchable; the form of the glove is retained through long wear.

Strong leather gloves are useful to drivers, fishers, and other outdoor workers. Gentlemen favour the lighter kinds of leather gloves for everyday wear, the kid glove being too light.

These are the leading kinds of glove; but we can hardly say that the catalogue of gloves is more than suggested by our selection. Every season a new kind catches the public fancy, or fashion leads back to a style we had thought gone out and passed away. Perhaps, however, it is our duty to hint that the differences are more apparent than real and intentional. For this the factory is chiefly responsible, and the factory worker simply goes on following the patterns.

Tools and Materials. As we have hinted, the home workshop bears a strong resemblance to the factory; the latter is practically the former on a large scale, with the necessary application of power-driven machinery. Some home workers are only glove sewers; but the real glover carries through every process of the operation, from the rough leather to the finished glove. He has, therefore, washing-tub, dyeing trays, staking blocks and tools, paring and doling knives, and tawing materials, such as we have already described in the section on Leather Dressing [pages 3163-6]. The tools of the handicraft glove sewer are few and simple. First are the needles, and these are of the very finest description, glovers' needles being of a special make. Next is the cutting stamp. Machine manufacturers, always on the alert for new trade, have managed to introduce that handy appliance, the stamp cutter, into even the small workshops, with large saving of time. Hand-blocks of various sizes and many models are used. The most ingenious block we have ever seen is the mechanically adjustable model, which can be made any size at the will of the operator. Sewing clamps are indispensable. Unlike the clamps of the saddler and the shoemaker, these clamps have very fine teeth, which clamp the work and afford a series of regular channels for the stitches. Here, also, we have the ubiquitous sewing machine, now running the hand sewer out of the factory. Besides, we use knives, scissors, hand punches, and other small tools. Last to be used, but not the least important, is the glovers' press. It is by means of this tool the fine shape and gloss are imparted to gloves. The wearing quality is not in the very slightest degree enhanced, but the buyers' eye is pleased.

Materials. The threads of the glover are composed of silk, cotton, and linen. For the highest qualities of gloves, silk is indispensable ; heavy gloves are sewn with the linen thread ; the most common thread is fine cotton.

Leather is, of course, the material out of which leather gloves are made ; but under the term we find a wide range of materials belonging to very different classes. Most of the smaller quadrupeds give their skins to the glove-makers ; but the material commonly used consists of the skins of kid, goat, chevrette, reindeer, sheep, calf, and colt. The finest and thinnest gloves are made from kid skins, derived from Switzerland and the mountainous districts of France, Saxony, and Austria. From South America, also, supplies of good kid skins are imported, as well as large quantities of sheep skins. Sheep and lamb skins are imported mostly from Russia, South Africa, Italy, Spain, Hungary, and the Balkan provinces.

22. LEATHER STAINING

Linings. Winter gloves are lined with various materials. The favourite lining is silk, and this must be of the best quality. A very fine flannel is used for men's and driving gloves. Padded, fur-lined, and various other kinds of gloves have been introduced for winter wear ; but these mentioned are really the staple kinds.

Trimmings. Of trimmings and fastenings the glover has a constant change, fickle fashion being the dictator in that department. At one time, the cuffs of a dainty gauntlet have to be embroidered in brocade style ; at another, silk of one colour runs in lines or curves round the wrists. The backs of the hands are embroidered or plain, in accordance with the fancy.

Fastenings. In fastenings, too, the fashions vary amazingly. Plain pearl buttons, embossed gilt, enamelled, or glass buttons, alternately gain favour. Patent spring catches of ingenious character are brought in every season for winter gloves. Some very pretty devices have been introduced for lacing gloves. Lacing hooks, set with pearls, turquoise, bloodstones, and other precious materials, have come and gone into and out of fashion, with silk, gold, hair, and chain laces. But for these the glover has to keep his eyes open and his inventive faculty alive. A new fastener of novel design will sometimes do more to make a business success than any degree of industry.

Leather Preparing. The appliances and methods of the home worker are various, and frequently primitive, though the product is generally of the finest class. In the factory a more uniform system obtains and may be more easily observed. First, the skins are brought to the sorter, whose business it is to classify the skins according to quality. Sorting demands high skill and great care, especially in these days of clever sophistication. Having been sorted, the skins are washed [**21**]. Soaked in tubs of tepid water, the skins are brought into a soft condition. As yet, the dollying tub has not been brought into the glove factory, and the driving out of the dirt and grease is still performed by the tramping feet of men, who get into the tubs and tread the leather. This operation is illustrated from Messrs. Dent, Allcroft, & Co.'s factory, to which firm we are indebted for the illustrations of this section.

In the washing operation, a considerable proportion of the egg yolk and flour dressing has been taken out, and a new dressing must be applied if the leather is to retain its softness and flexibility. The egg-yolks are made into a paste with flour, water, and a little alum, the dressing being thoroughly worked into the body of the leather.

Dyeing and Staining. Glove leather may be dyed or stained by three or four different methods. We may choose to stain one side by brushing, plunge the whole skin into the dye-bath and colour both sides, or we may wait till the gloves are made and stain them in the finishing process. The two first methods belong to the department of leather preparation, and naturally come under observation here.

Vegetable dyes are used. The dye having been made ready, the skins are stretched out on a leaden table [**22**], and brushed over with a mordant, generally a simple alkaloid, to make the colour lie. Then the die is brushed on, coating after coating being applied till the required depth of shade has been obtained. Next, a fixer, or striker, is put on, iron liquor being commonly used for tan and dark shades. Rinsed in water, the skin is then hung up in the hot stove to dry.

One side only of the leather is dyed by the brushing process, the aim being to keep the inner side of the glove white.

When both sides are to be coloured, the

plunging method is used. The skins are simply immersed in the dyeing liquor, and worked through till the material has been thoroughly impregnated with the colour. Otherwise, there is little difference in the two operations.

Open air drying is preferred by the glovers who work at home; but the factory drying is done in a large stove in which a current of air is constantly kept going by power-driven fans.

Staking and Paring. Drying has caused the skins to harden and wrinkle. Softened a little with damp sawdust, the skins are broken over the staking knife—a blunt, semi-circular-blade fixed on the bench. Staking smooths the grain side; but the flesh side of the skins is rough. Fixing the skin flesh side upward, the worker takes a "moon-knife," so called from its shape, and carefully pares away the rough parts. This is delicate work, for the knife is keen and the skin is thin.

23. GLOVE PUNCHING

Doling and Sorting. Doling is a shaving operation, applied only to the highest class of fine kid skins. Laying the skin, flesh side upward, on a slab of marble, the operator shaves the leather with a flat blade shaped like a broad chisel, producing a smooth, hard surface.

Some defects in the skins may have been brought into evidence during the foregoing operations, and they are carefully inspected again, and finally classed for glove-making.

24. GLOVE-SEWING BY HAND

Cutting Gloves. A glove seems a thing easy to cut till you try it. Like a great many acts of craftsmanship, it is simple to describe and very difficult to do. A side of leather is first cut into pieces the size required—that is, double the breadth and a little more than the length of the glove to be made. Double over a pair of the pieces, folding the one from left to right, and the other from right to left, leaving a margin on the under half. The part lying undermost is the back of the glove, and is made larger than the front. Divide the top part of the doubled leather into four, the length of the fingers, with three straight cuts. Open out the front, so that it lies flat on the board, and cut from the edge of the fold outward a slightly oval circle. The hole is the thumb socket, and the three cuts have made the fronts and backs of the four fingers of the glove. Gussets are required for both sides of the second and third fingers, and one side of the first and fourth; and the thumb of the glove must also be cut out. Make sure that the colour and texture of the leather is exactly the same as the body of the glove, and cut to size.

By a slightly different method of operation, after being assorted as to quality and size, the skins are transferred to the cutter, who cuts them into oblong pieces of the size required, which are turned over to the puncher [23], who takes two or three pairs at a time, and subjects them to the action of a press carrying a punch corresponding to the size of the gloves to be made, which forms the hand, with all the necessary slits, openings and button-holes. The thumbs and *fourchettes*, or pieces between the fingers, are punched separately.

There are ten different sizes, from 5¼ to 8, for ladies' gloves; thirteen, from 7½ to 11, for gentlemen's; and seven, from 5 to 6½ for misses. Each of these sizes has a corresponding plate which serves as guide to the cutter.

Pointing. On the backs of gloves, various forms of ornamental sewing, or tambouring, are wrought. Pointing, as the operation is technically named, is generally done by hand on the backs, before the gloves are sewn. Plain lines of stitching are sometimes preferred by fashion, and these are put in either by hand or by machine. Heavier patterns are tamboured. First, the holes are stamped in the backs with a mallet and point called a preen. Then another worker, sitting at a frame [25], works the threads into the patterns with a crochet hook. A sewing-machine has been invented which imitates the hand tambouring.

Sewing. Glove-makers speak of three kinds of sewing [24]: roundseam, prickseam, and pique. Roundseam is the oldest and highest kind of work. By this method the glove pieces are put together and sewn over the outside edges, forming the round cord familiar to glove wearers. Prickseam is the coarsest and strongest sewing. The two edges of leather are laid together, and a narrow seam made along the side. the double edge standing out from the glove. Pique is neater though not so strong, the one edge being placed under the other, and only one ply of leather showing.

Sewing. First in point of time, and yet first for excellence, the hand method [24] of roundseam is worthy of primary attention. Here comes in our sewing clamp, or " donkey " frame. Adjust the pieces to be sewn neatly together, and with the foot press the clamp, and with needle and thread begin to stitch. In the clamp are very fine teeth, numbering twelve to the inch, and it is between these teeth the needle passes every stitch. Pass the needle through one side and bring it out at the other, making the little ridge to be seen on all fine gloves. The work is tedious and trying, but practice makes even difficult things easy. Two points are especially important in the making of a glove—the insertion of the gussets and the sewing in of the thumbs. If the gussets are uneven, the work is spoiled ; if the thumb sits badly, no amount of blocking will put it right. Another very vital part of the glove is the finger-tip. Badly-sewn gloves first begin to show their weakness there.

25. EMBROIDERING OR TAMBOURING THE BACKS OF GLOVES

Before the sewing machine was brought to its present state of perfection no one could make a glove wholly by machine—at least, not a glove that would stand comparison with a hand-made glove. Now, however, the machine-made glove is practically unrecognisable from the product of the hand. Some of the cheaper classes are not put out to compete with the high-class glove, and they are seamed in a style that condemns them at once, generally prickseam, which is suited best for heavy gloves. No glover has any reason to fear the competition of that quality of glove. But the makers of machines, like persistent suitors, would not be denied, and persevered, till a sewing machine was made that could sew gloves in exact imitation of the hand-sewing. These machines are now in use in all the best factories, and require no special skill to work them. The machinist puts the pieces together, and the machine does the rest. A difference between the hand-made and the machine-made glove can, of course, be observed, and it tells in the wear ; but the average purchaser must rely on the good faith of the man who sells.

The varieties of glove mentioned are not all sewn or put together in the same way. Even gloves of the same pattern may be constructed differently. Some kid gloves have small diamond gussets set in to allow for the expansion of the fingers, and others have not. Those smaller gussets undoubtedly assist in fitting the glove to the flexure of the hand, and take the strain of movement off the fingers.

Long-armed and lined gloves present no great technical difficulties. The cutting of the long-armed glove is the main part ; the sewing is plain and easy. Lining is cut to the same size as the body of the glove, and sewn in with the gussets. The lining of the fingers is simply back and front.

Buttonholing and hemming are points that must be skilfully done on good gloves. The buttonholing is simply the crossover stitch common to all buttonholes ; but the hemming of the edge and the sides of the glove is a delicate operation. No stitch must appear on the outside of the glove ; every stitch catches the inner skin and holds by it alone.

Dyeing and Finishing. Fine kid gloves are coloured on one side only, for obvious reasons. If not stained in the skin, the glove must be coloured in the finishing.

After the work of sewing has been completed, the glove is blocked—that is, drawn on a wooden block of its size. Carefully fixed, so that not a crease or wrinkle appears, the glove is painted over with the colour, and left to dry. The first coat is absorbed by the leather, which appears almost as white as before. A second coat is applied, and a third. Now we have a solid colour ; but it is dull and hard.

The stained glove is gone over with the polishing bone —a rounded piece of hard bone or ivory, which is rubbed on the surface. It lifts off every vestige of superfluous colour and gives the leather a fine, smooth surface.

In the factory we have a different and quicker method. The dyed gloves are pressed at moderate heat and polished in a few moments.

Now the gloves are looking fairly well, but a finishing touch is yet required. Left in that condition, the gloss would leave them after a single day's wear. To fix the gloss, and add a smooth skin, the white of egg is applied with scrupulous care to the whole surface of the leather. When thoroughly dry, we press the gloves, and they are ready for the market.

IRRIGATION AND CANALS

Natural and Artificial Irrigation. Assuan Dam. Considerations in Canal Construction. Types of Canals

HYDRAULICS
continued from page 5336

By Professor HENRY ROBINSON

IRRIGATION may be defined as the application of water to the purposes of agriculture, either naturally or artificially. The former is dependent upon the rain and the flooding of the land in times of the maximum discharge of rivers. The latter is effected by means of canals and tanks, sometimes supplemented by pumping.

There are two systems of irrigation—*basin* irrigation and *perennial* irrigation. The basin system consists in turning the waters of the rivers on to the land in flood time. In Egypt, the land is divided up into large areas called *basins*, and the water is allowed to remain on them at an average depth of about 5 ft., for about forty days, and it deposits the silt which the water contains, after which it is drained into the river. With perennial irrigation, the land is watered all the year.

Irrigation in Foreign Countries. The storage of water for irrigation purposes has received more attention abroad than in this country. This is mainly due to the fact that in countries like Egypt and India there are very long periods without any rainfall. Egypt, in fact, is a country which is practically without rain, the rainfall in Cairo being on the average only about 1½ inches per annum, so that it is dependent entirely on the River Nile for its supply of water. In this country, however, although the rainfall is more or less capricious, there is, as a rule, sufficient during the year to enable agricultural operations to be carried on without the aid of artificial irrigation, although some soils are benefited by irrigation. Practical irrigation in this country is confined to damming up streams so that the water flows up ditches and floods the adjoining land.

Irrigation in Egypt and India. For irrigation works of great magnitude, India and Egypt afford some of the finest examples. Some idea of the magnitude of these works may be obtained when it is stated that in 1901 the area irrigated in India from Government canals was 20 million acres, and the total length of main canals was 13,000 miles, with 31,000 miles of distributors. In Egypt, the construction of the "barrages" a few miles to the north of Cairo, and in more recent years the dam at Assuan, serve as examples and will be explained later. In India, many storage reservoirs have been constructed for irrigation purposes under the Public Works Department. Some of these are made with concrete or masonry dams, but the majority are made with dams of earthwork, the material being brought from the neighbouring country and consolidated by the native labourers, who bring the materials in small baskets on their heads, and also by the employment of elephants to tread in and consolidate the mass. Some of the finest works in the world are made in this manner. In storing enormous volumes of water thus dealt with, one of the most important parts of the work consists in providing for the escape of the excess water when the basins or reservoirs are full.

Natural Irrigation. All rivers in times of flood carry a great deal of matter in suspension, generally a mixture of alluvial matter and sand. In the upper reaches, the velocity is generally sufficient to carry this forward, but when the river reaches the valleys this suspended matter tends to get deposited, and so the bed of the river is raised above that of the surrounding country, thus facilitating irrigation. The rivers in flood time carrying vast quantities of this suspended matter, or silt, overflow their banks and deposit the silt on the surrounding land. The fertilising properties of this deposit are great, and after the deposit has taken place, the water is run off the land and the crops are sown on it.

On the River Nile in the old days, banks were formed along each side of the river above flood level. At right angles to them other banks were carried dividing the land up. Canals were cut into the river banks during low water ; in times of flood the water was carried on to the land by this means, and the suspended matter deposited there. At the end of the flood the water drained off and the crops were sown on the deposited mud. By this system only one crop could be raised each year.

Artificial Irrigation. On the other hand, in the upper reaches of the rivers, the banks are usually higher than the river bed, so that in order to irrigate them (as in Northern India) it is necessary to tap the river in the higher reaches to obtain enough head to command the high levels. The usual method of conveying the water to the land is by means of canals, and they may be divided into two classes—either for irrigation pure and simple, or combined with navigation, to enable the produce of the land to be transported. In designing canals care must be taken to note the geological formation of the country through which the canals have to pass, in order to determine their proper slope to prevent scouring the beds. When the stratum is hard, the slope, of course, is immaterial as far as scour is concerned. When, however, navigation is combined with irrigation, the slope is material, in order to get as small a velocity as is consistent with the successful carrying forward of the silt, which would otherwise deposit and fill up the channel. Also, if the channel is to be navigable, a certain minimum depth must be allowed for, which is deducted from the quantity required for irrigation purposes. The calculations for arriving at the size of the channel may be made with the formula already given in considering the discharge of rivers. The coefficient N in Kutter's formula is generally taken as 0·025 for this class of work. It has been found, however, that in some canals in India, which had silted, and by this means adjusted themselves into the best form of channel for their particular condition, a discharge of from 20 per cent. to 25 per cent. in excess of that given by the formula had been obtained.

With regard to the minimum velocity to prevent the deposition of silt in Egypt it was found that when the velocity was less than 1·8 ft. per second it would occur. With regard to the maximum velocity (as previously stated), it must depend to some extent on the nature of the bed and banks. In India, 3 ft. a second has been considered to be a safe maximum velocity. When possible, in constructing the canal, the excavated material should closely approximate to the amount necessary for the banks, and this would be the most favourable condition of affairs. Also, when curves have to be resorted to, they must be very flat, in order to prevent bank erosion.

Irrigation in Steep Country. When the slope of the country is steep, falls have to be resorted to in order to keep the gradient within limits. In this case the velocity is greatly increased, and is consequently felt for a considerable way up the canal. It then becomes necessary to protect the beds and banks, and to make them of such material as will resist this increased velocity. The simplest canals in India are called *inundation* canals. Cuts are made from the rivers inland, and are generally run parallel to the fall of the country or river course, the land being watered when the river is in flood. A permanent supply for canals is generally a river carrying a perennial stream, the head of the canal being located high up on its course, so that the water is more or less free from deposits.

This is known as *perennial* irrigation, as the land receives water all the year round. The quantity of water required depends on the area to be irrigated and the nature of the crops. In Upper India 1 cubic ft. per second has been found sufficient to raise food crops on 200 acres. This, however, varies, as is shown by the following data. On the Eastern Jumna Canal, which has given some of the best results in Northern India, the average depth has seldom been less than 2 ft. 6 in., which would mean about 1 cubic ft. per annum for 300 acres. On the Ganges it has been about the same, and on the Agra Canal the average was 5 ft. 6 in. in one year, whereas in the year following it was 4 ft. 6 in., while it exceeded 6 ft. and 7 ft. on some of the tributaries.

In Southern California, for grape crops and fruits of that class, 1 cubic ft. per second will irrigate 500 acres. In Lower Egypt the year is divided into three seasons—séfi, or summer, nili, or flood, and chitawi, or winter.

The summer crops are cotton, rice, sugar-cane, melons and cucumbers. In the flood season maize is grown, which is the staple food of the agricultural population. During winter the crops are wheat, barley, beans, and clover. Many thousands of water-wheels and engines of various kinds are brought into use for irrigation purposes. The summer crop is the most difficult and expensive to raise, and is irrigated from summer canals, which are supplemented in floods by shallow canals that are used only at that time.

To assist summer irrigation barrages have been constructed at the head of the delta to maintain a higher water-level. The position of these barrages is at a point slightly to the north of Cairo, where the Nile divides into two branches, known as the Rosetta and Damietta. The Rosetta barrage is 1,437 ft., and the Damietta 1,709 ft. These are open dams, built across the streams, provided with regulating gates, which are lowered into position by means of chains attached to the gates and worked by crabs.

Assuan Dam. More recently the great work at Assuan, which is familiar to everyone, has been completed, and will be referred to only briefly. This great dam creates a vast reservoir which supplements the discharge of the Nile during the summer months, and is estimated to hold 37,612,000,000 cubic ft., and gives a better supply of water in summer than was available before its construction.

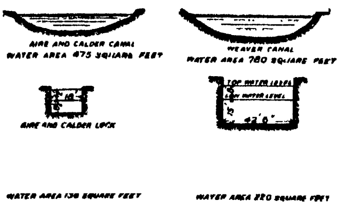
The problem which had to be solved was how to deal with the vast quantities of silt which are brought down by the river in flood, and which would have ultimately filled up the reservoir. This was got over by providing the dam (whose length is about 1¼ miles), with sluices at various levels of sufficient capacity to discharge the whole of the waters in time of flood. These are left open until the water has got sufficiently clear, when they are gradually closed, and the water is then stored.

Indian river weirs are different to the barrages on the Nile, being formed by a solid wall right across the river, pierced by sluices. The barrages in Egypt, which have been mentioned, consist of platforms which are laid across the river, and on which piers are raised and arches thrown over, so that the flood can pass through at its highest level, thus preventing deposits.

Canals. Canals provide the means for transporting goods by boats and barges through inland districts, or of connecting up rivers, and thus opening out great lengths of waterways, as in Russia, France, and other countries. An instance of this is the canal joining the Obi and Yenesi rivers in Siberia, which opens up a waterway of over 3,000 miles by a canal about five miles in length. Since the development of railways in this country, canals have to a great extent been superseded, although those of the Aire and Calder and the Weaver are exceptions. Many years ago the writer converted the Gwendraeth Valley Canal in Carmarthenshire into a railway. This was used for bringing anthracite coal from the collieries in that district to Burry

Port for shipment, and for transport by the Great Western Railway, which passes through this district.

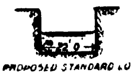
Another reason why canals have not succeeded in fulfilling their object to purpose is the want of uniformity of gauge of the various canals and locks. This was demonstrated in a paper recently read before the Institution of Civil Engineers by Mr. A. J. Sauer, who exhibited sections of various canals and locks [13], which thoroughly illustrate this point.



AIRE AND CALDER CANAL
WATER AREA 475 SQUARE FEET
WEAVER CANAL
WATER AREA 780 SQUARE FEET
AIRE AND CALDER LOCK
TOP WATER LEVEL
LOW WATER LEVEL
42'0"
WATER AREA 136 SQUARE FEET
WATER AREA 220 SQUARE FEET

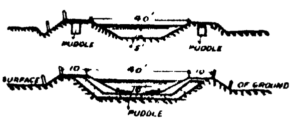
13. SECTIONS FOR CANALS AND LOCKS

He also suggested that a standard should be adopted of the form illustrated in **14**. The lock should be 230 ft. in length, as this would accommodate eight of the ordinary narrow boats of 7 ft. in width, with the tug for towing them.



14. STANDARD FORMS OF CANAL AND LOCK SECTIONS

As a canal is essentially a still waterway, it is generally more or less tortuous in its course, in order to follow the contour of the country, and to save great changes in level. When these changes of level, however, are unavoidable, locks, lifts, or inclined planes have to be resorted to. When locks are used—and this is the most general way—if the fall is considerable, the change of level is effected by what are termed *flights of locks*, being a series of locks at different levels. Where the strata is permeable, it becomes necessary to provide some form of lining to prevent leakage, a very common plan being to use clay puddle, although concrete has been employed. Figure **15** shows two typical forms of canals, the lower figure being lined with puddle across the whole section, while the upper one has only a vertical puddle wall, which is usually made about 3 ft. thick, and which is always necessary. Professor Rankine gives the following examples of the extreme and ordinary dimensions of canals.



15. METHOD OF PREVENTING LEAKAGE IN CANALS

	Breadth at bottom in feet.	Breadth at top water in	Depth of water in feet.
Small canal	12	24	4
Ordinary canal	25	40	5
Large canal	50	110	20

The inland canals in this country afford, as a rule, sufficient depth only for barges drawing from 3 ft. to 5 ft. of water, and the locks provide for boats about 70 ft. in length, and 7 ft. to 15 ft. in width. In the case of the Aire and Calder and Weaver canals, these figures have been greatly exceeded, as the following will show. The maximum size of vessels in the former is 120 ft. × 17 ft. with a draught of 7 ft. 6 in., and in the latter 120 ft. × 25 ft. with a draught of 10 ft. 6 in. The general width of a canal should be sufficient to allow two boats to pass one another, and the depth and sectional area of waterway should be sufficient to cause no increase of the resistance to the motion of the boat other than that due to the water.

Requirements of Canals. The following rules generally satisfy the above:

1. The least breadth at the bottom to be twice the greatest breadth of the boat.

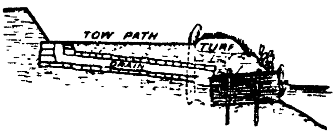
2. The least area of waterway to be six times the greatest midship section of the boat.

3. The bottom of the waterway to be flat, and the sides, when of earth, to be not steeper than 1½ to 1; when of masonry, they may be vertical, but the canal should have about 2 ft. extra width at the bottom.

4. The least depth of waterway should be 1½ ft. greater than the greatest draught of boat.

A towing-path should be provided at one side of the canal, usually about 12 ft. in width at the top, and about 2 ft. above the water-level, and should be made to slope away from the canal, in order to give a better foothold for the horses.

It is necessary to protect the sides of the canal about the water-line on account of the wash, usually about 1 ft. above and 1 ft. below the water-line. This can be accomplished either by pitching, or by fascines of brushwood. Figure **16** shows the method that was adopted at the Foss Dyke Canal, as well as the method of draining the towpath.



16. FOSS DYKE CANAL TOW PATH

The amount of water required for canal purposes can be estimated as follows: Waste of water by leakage of the channel, repairs, and evaporation, equals the area of the surface of the canal multiplied by ⅙ of a ft. nearly. Current from the higher towards the lower reaches, produced by leakage at the lock gates, represents from 10,000 to 20,000 cubic ft. per day, in ordinary cases. For the expenditure of water in passing boats from one level to another, let L denote a lockful of water—that is, the volume contained in a lock chamber, between the upper and lower water-levels—and B the volume displaced by a boat. Then the volumes of water discharged from the upper pond, at a lock or a flight of locks, under various circumstances are as shown in the table on next page. The minus sign prefixed to a quantity of water denotes that it is displaced from the lock into the upper pond.

Canal Locks. Rankine has deduced from these figures that single locks are more favourable

		L - B - B	
2n boats, descending and ascending alternately			empty full

trains, each of n boats rst descending, and d ascending	..	.	Full

to economy of water than flights of locks; that at a single lock single boats ascending and descending alternately cause less expenditure of water than equal numbers of boats in trains; and that, on the other hand, at a flight of locks, boats in trains cause less expenditure of water than equal numbers of boats ascending and descending alternately. For this reason, when a long flight of locks is unavoidable, it is usual to make it double—that is, to have two similar flights side by side, one for ascending boats, and the other for descending boats. Water may be saved at flights of locks by the aid of side ponds or lateral reservoirs. The use of a side pond is to keep for future use a certain portion of the water that is discharged from a lock, when the locks below it in the flight are full, which water would be wholly discharged into the lower reach. Let a be the horizontal area of a lock chamber, A that of its side pond; then the volume of water so saved is

$$LA \div (A + a).$$

A substitute for flights of locks is the hydraulic lift. One of these was adopted to connect the Weaver with the Trent and Mersey Canal at Anderton, the difference of level being 50 ft. It was capable of raising eight barges up and down in an hour, but the cost of such lifts is very great.

The canal must have a regular supply of water to compensate for losses due to leakage, evaporation, and the water used in the locks. This supply may be obtained from rivers, lakes, or springs, and must be sufficient to tide over times of extreme drought. In some cases the supply is obtained from artificial reservoirs, constructed in the upper reaches of the stream supplying the canal, and providing a storage in flood time for use during dry weather.

Ship Canals. The chief difference between ship canals and ordinary inland canals is in their size, as the former have to accommodate large sea-going vessels. On account of their size and depth they are able to be carried only through country where there is not much change of level, partly on account of the quantity of excavation involved, and partly owing to the necessity of providing locks, with the attendant cost of construction, and the delay caused to the passage of ships through the canal. The object of ship canals may be either to provide a connection between a large town at a short distance from the sea or large tidal river, and a seaport, as, for instance, the Manchester Ship Canal, or by cutting across land to connect two seas, and thus to provide a shorter course for sea-going vessels, as, for instance, the Suez Canal, which connects the Mediterranean and the Red Sea by a canal about 100 miles in length. Narrow necks of low-lying land, intersected by lakes or rivers, afford the best places for constructing ship canals. Ship canals may be divided into four classes, as follows:

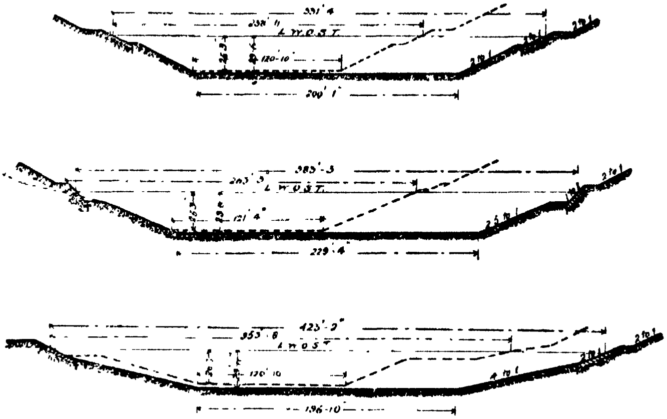
1. Canals which, in joining up two seas, traverse high districts involving locks on both sides of the summit, as, for instance, the Caledonian Canal.
2. Canals which pass through low-lying disdistricts, as in Holland, with locks only at the extremities to hold up the water in the canal, at times of low tide, and to prevent the sea entering at high water.
3. Canals joining up two seas without the intervention of locks, as the Suez Canal.
4. Canals providing a direct route from an inland town to the sea, of which the Manchester Canal is an example.

The scope of the present article will enable the writer to deal only briefly with each of these types of canals. He will therefore confine himself to a brief description of one of each class.

High Lock Ship Canals. In ship canals of the first kind—namely, those that have to attain an elevation by means of locks, before descending by similar means—we have the Languedoc Canal in France and the Caledonian Canal in Scotland. The latter, although of very old construction, is, however, typical of this class. It serves the purpose of connecting the east and west coasts of Scotland, through a series of fresh-water lakes—namely, Lochs Ness, Oich, and Lochy. The total length of the canal is about 60 miles, of which about 23 is artificial, the remainder being through the lakes. The artificial portion was made 120 ft. wide at the water level, 50 ft. wide at the bottom, and 20 ft. deep. Regulating locks are provided between the lakes, and sea locks at the entrance at both ends. The total rise to Loch Oich, which is the summit, is about 100 ft. and is accomplished (beginning at the eastern side) with a flight of four locks to Loch Ness, and a further seven, including one flight of five, to Loch Oich. From there it descends by two lochs to Loch Lochy, and then by a flight of eight, and a further two locks, it enters the tidal lock at the western extremity. The locks are about 180 ft. long, by 40 ft. wide, with 8 ft. rise.

End Lock Ship Canals. Of the second class—namely, those which pass through low-lying districts and connect two seas—the canals of Holland are examples, as, for instance, the Amsterdam Canal. They have locks at their entrances to provide for the variation of tide levels, and are dependent for their water chiefly on the sea. The water-level is approximately the same throughout, being regulated by sluices or locks.

Lockless Canals. An illustration of canals of the third class—namely, for the connection of two seas without the intervention of locks—is the Suez Canal, which connects the Mediterranean and Red Seas. The total length of the canal is 100 miles. Figure 17 shows cross sections at various points. These are taken from a paper by Sir Charles Hartley, and published in the "Proceedings of the Institution of Civil Engineers." In the figures the cross section in dotted lines shows the form of the Canal in 1899, and the full lines that of the proposed ultimate shape. The route chosen for the canal passed through four depressions below sea-level, which are consequently converted into extensive lakes, with an aggregate length of 27 miles. At the same time it was necessary to excavate a certain amount of the whole course, with the exception of some eight miles where the natural depth was greater than that of the channel.



17. SECTIONS OF SUEZ CANAL

Manchester Ship Canal. The Manchester Ship Canal is the example taken for illustrating how an inland town may be served by a canal for the purposes of improving or providing a route to the sea. The length of the canal is 35½ miles, and this connects Manchester with the Mersey, and also opens up the communications with Liverpool. The canal enters the River Mersey at Eastham, about six miles above Liverpool, by means of three locks parallel to one another, and of the following dimensions, 600 ft. by 80 ft., 350 ft. by 50 ft., and 150 ft. by 30ft. These locks maintain a depth of 26 ft. in the canal, subject to certain increases in the tide levels. When extra high tides are experienced, the excess water entering the canal is returned to the river through sluices provided higher up the canal. From this it will be seen that the first part of the canal is semi-tidal, and this is so for the first 21 miles. The locks at Eastham are opened at high tide, and the canal is, therefore, an open cut to the sea. The total rise of the canal above ordinary water-level in the tidal portion is 60 ft. 6 in., and is accomplished by locks in four changes of level, the locks being of two sizes, side by side, and of the following dimensions, 600 ft. by 65 ft., and 350 ft. by 45 ft. The minimum width of the canal at the bottom is 120 ft., and this is increased to 170 ft. at the Manchester end. Figure 18 shows sections of the canal as carried out, and the methods adopted for protecting the banks under varying conditions. Another feature of the canal is carrying the old Bridgwater canal across it on an aqueduct which enables barges to pass over. The limited water supply of the old canal, the loss of water and the time that would have occurred if two sets of locks had been constructed to enable barges to cross the ship canal on its level, as well as the inconvenience to vessels using the larger canal, made it advisable to adopt a movable aqueduct, which was a convenient way of dealing with the crossing of two canals. This was practically an iron trough filled with water, resting on a central pivot, and revolving like a swing bridge, leaving a passage on each side for vessels to pass along the canal. At other times it was closed, enabling the Bridgwater Canal vessels to pass over. The new aqueduct has two movable spans 90 ft. each, with a waterway 19 ft. wide and 6 ft. in depth. It works on a central pier 400 ft. long and 50 ft. wide, which carries also the adjacent road bridge. The pier is mainly built of cement concrete, with brickwork and granite in the part that takes the weight of the aqueduct (1,400 tons) including the water which is always in the iron trough through which the barges pass. The sides of the trough are 1 ft. above the water-level. It is carried by side girders 234 ft. long, 22 ft. 3 in. apart, and 33 ft. deep, tapering off to 28 ft. 9 in. at the ends, with a side towpath carried on a gallery 9 ft. above the water-level. Water-tight iron swing doors are provided at each fixed shore end, and at each end of the trough. The gates and trough are worked by hydraulic power, and the trough can be swung with the barges in it.

HOW TO MAKE BASKETS

The Ancient Industry of Basket-making. Cultivation of the Willow. The Tools Employed and their Uses. The Different Kinds of Strokes

PRACTISED as a personal art, each man for his own uses, in the days of rude barbarism, Basket-making very early became a skilled craft, and one of the recognised trades in every small community. At present it is one of the few genuine handicrafts left us by the rapid progress of mechanical invention.

The Scope of the Industry. We speak of the trade as basket-making: but perhaps the more scientific definition would be willow and cane weaving. For the scope of the industry has become very wide. Among baskets there is a large variety—round, square, oval, and flat; laundry baskets, wine baskets, coarse packing, protective casing for fragile ware, such as stone jars or glass carboys, luncheon and tea baskets, chemists' baskets, baskets for fruit, vegetables, provisions and clothes. Fancy baskets, work baskets, and various light forms have come into extensive use, and constitute an important branch of the trade. Closely allied to the fancy kind of basket comes the toy trade, growing every year more important. Doll cradles, chairs, tables, and numerous imitations of household articles, are made to please the childish fancy.

But it is in the larger kinds of wicker-work that British basket-makers have made the greatest advances during recent years. Not only chairs, lounges, travelling hampers, flower-stands, and other such wares, but car bodies for motors, pony carriages, and many large pieces of wicker-work have been successfully made.

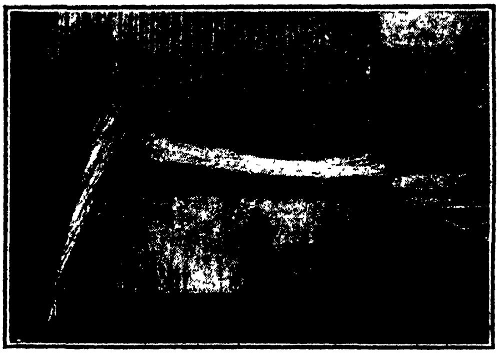
We have mentioned cane along with the willow in attempting to define the trade. Whole cane has been in use for centuries, but it is difficult to work, and requires great strength in the hands to manipulate. In more recent years the introduction of cane-pith, or, as it is sometimes termed, cane-pulp (a material of more facile handling even than willow) has led to a much wider employment of cane products especially among amateur workers. By the skilled basket-maker, cane-pith has come in as a very handy and serviceable addition to his material. It is largely used, often in conjunction with willow, for chairs and luncheon baskets.

The basket-maker uses a considerable variety of raw materials; in addition to willow and cane, rush and straw plait, he takes from the wood-worker many kinds of prepared woods; from the iron-worker, he asks and buys different forms of iron: from other industries he requires various services. But, in the main, the materials of the trade are the willow and the cane.

Willow Culture. Osier farming is a branch of agriculture of which the public hears very little; but, when carried on with skill, and under proper conditions, it is a profitable crop. A special characteristic of the willow family is its fondness for moist, but not marshy nor water-logged alluvial soils. Only very coarse kinds of osier are derived from lowland soils, and the best results are obtained from drained loamy upland soils, well cultivated. The chief species are classified as osier and fine, each subdivided into hundreds of varieties, bearing local names, such as: stone osier, chancellors, red-bud, new-kind, long-bud, Spaniard, French, Pomeranian. The land should be well trenched before planting, and if not subject to alluvial flood, carefully manured. After planting, the osier beds should be hoed over and weeded several times during the year. When this is done, a crop of fine osiers, in normal seasons, is the reward of the cultivator. After cutting, the willows are classed, the finest being peeled, and the coarser kinds, after being well dried in sun and air, stacked in their skins. To produce what are technically named *buffs*, the rods, generally of fine quality, are boiled in their skins before stripping. The tannin of the bark imparts to them a fine buff colour.

Sorting the Willows. The different kinds of willow come to the basket-makers in sorted bundles. Unstripped are called brown, the other two kinds are known as white and buff. Old names still survive in the trade for the different sizes of brown, white, and buff. The method now most commonly adopted is to class them as follows: twig, short small, long small, threepenny, middleboro', and great. The names differ a good deal, but this classification is sufficient for all practical purposes.

The willows are soaked in tanks for a period [1], the length of which is determined by the kind and the purposes for which the material is to be used, and are again more carefully sorted before they are used for the finer kinds of work

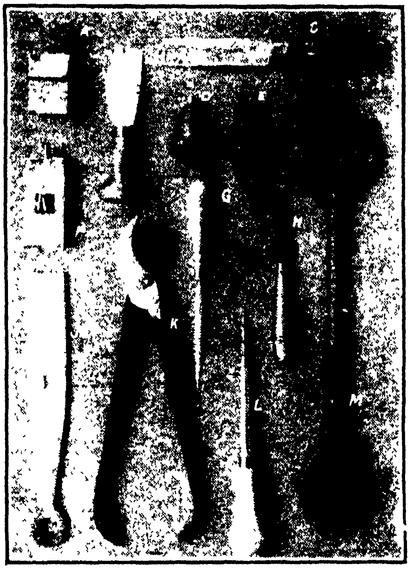


1. WATER TROUGHS FOR SOAKING WILLOWS

Cane. Derived from the "rattan" of commerce, many species of which grow profusely in nearly all parts of our Indian Empire, the cane is imported in bundles of 100 each, from 15 to 20 feet long. The finest skeins, made from the flinty epidermis of the cane, are of great length, the tough, woody substance that remains being drawn through cylinders of varying diameters and sold as cane-pulp.. The cost of the material has led to the invention of cheap substitutes, none of which, however, have proved serviceable enough to merit mention.

Cutting Tools. Basket-making, as has been said, is a skilled handicraft; no machinery is employed in the workshop itself. The basket-maker does the whole of his work by the aid of the very simplest tools, of which a kit, supplied by Mr. G. Buck, is shown in 2. Taking the cutting tools first, we note the shears, K. Shaped like a pair of strong pincers, with long legs and short blades, the shears give the worker great power, enabling him to cut through fairly strong osiers very easily. Three knives, B, C, and H, are shown, though many basket-makers contrive to get along with one, or, at most, two. The *picking knife*, B, is curiously shaped; straight on the back, the face of the blade slants forward at an angle to the head, which is cut off at an obtuse angle. The *shop knife*, C, is a plain blade, and the smaller knife, H, has a very fine blade, keen and pointed.

Tools for Skein-making. A very important group of tools are those for making skeins, D and E. Made of hard wood, with a round head fitting into the palm of the hand, the body of the *cleave* is wedge-shaped, with grooves running from point to neck. The number of grooves determines the number of parts into which the rod is to be split. If we are to get three skeins, the cleave with three grooves, D, is used: if four skeins are being made, the four-grooved cleave, E, comes into operation. With the knife make the cuts in the top of the willow; the grooves of the cleave are fitted into the splits, and by pushing steadily through to the end you obtain the rough skeins. After being split, the osier or fine skeins have two faults which should be corrected before using. The pith of the heart of the split willow remains on the inner side of the skein: the taper of the natural growth of the wand from butt to tip shows itself in the gradual thinning of the skein. To remove the pith, and make the skein equal in **all** its length, we have two kinds of tool, the one called the upright, F, and the other the shave, A. In principle, both tools are the same, but in form very different. In the *shave*, the cutting tool is a steel blade placed in a graduated position towards an iron bed. The blade having been set to the thickness required, the skein is drawn through with the right hand, while the left thumb guides it against the blade. In this way the skein is planed, and an equal thickness obtained.



2. TOOLS USED BY BASKET-MAKERS

a. Shave *b*. Picking knife *c* and *h*. Shop knives *d* and *e*. Cleaves *f*. Upright *g*. Awl *j* Iron *k*. Shears *l*. Bodkin *m*. Commander or Dog

The *upright* is rather more ingenious, the cutting tools being contained within a holder. The blades having been set by thumbscrews to the breadth we think the skein will stand from end to end, we draw it through the upright, cutting away irregularities. Now the skeins are ready for any purpose.

Other Appliances. Two round-pointed *bodkins*, L, one long and one short, are required for making openings, either in the thick osier or between the woven work. An *awl*, G, is sometimes added. Resembling closely a broad, strong file, with a round head for handle, the *iron*, J, is useful for driving the work close, or for sending home tightly-fitting stakes.

The fitness of the names the basket-maker has applied to his tools comes out vividly in the *commander* or *dog*, M. It is a strong iron rod with two teeth at the one end and a ring at the other. This tool is used for straightening crooked sticks, and other similar purposes.

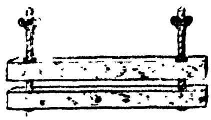
Closely resembling a horizontal vice, the *screw block* [8] is used for holding the sticks of the covers and bottoms of square baskets. The ends of the sticks, after being *slipped*, are inserted between the blocks, and the screws fix them firmly in position for the worker to weave the rods over them. These tools are made of beechwood, 2 in. square, and from 24 in. to 36 in. long. The threaded bolts of iron are fitted with screws for working with the finger and thumb, or the bodkin.

The basket-maker has his own *yard stick*, generally a wand, marked in inches. In the workshop, we find *the plank*, the *work board*, and other appliances of general use, varying in kind with the styles of work carried on.

Definitions of "Strokes." *Randing* is the weaving of a single rod in and out on the sticks which form what might be called the warp of the basket. *Working a pair* is the weaving of two rods alternately over one another. *Slewing* is working with two or more rods at the same time. The opposite of the pair is the *fitch*, in which two rods are worked under each other. The most complex of the common strokes is the *wale*, three or more rods being woven over and under each other in regular sequence. There are other kinds of basket-weaving, which are shown in the descriptions of the various methods of bordering.

Making a Round Basket. The shortest and simplest way of initiating the beginner into the various strokes is to bring before him a round basket in which they are exemplified. Of course, the apprentice in a basket-making shop is not so quickly given the knowledge of the rudiments of his trade. He has first to find his way about, doing odd jobs of sorting, and making himself generally useful: then he is given small parts to do, under the superintendence of the journeyman whom he is helping. Surrounded by expert workmen, examples of dexterity always coming before his eyes, the apprentice can afford to bide his time.

Suppose, then, we have undertaken to make a strong, large basket of round shape, such as 4, which is reproduced by permission from the "Journal of the Society of Arts," January 11, 1907.



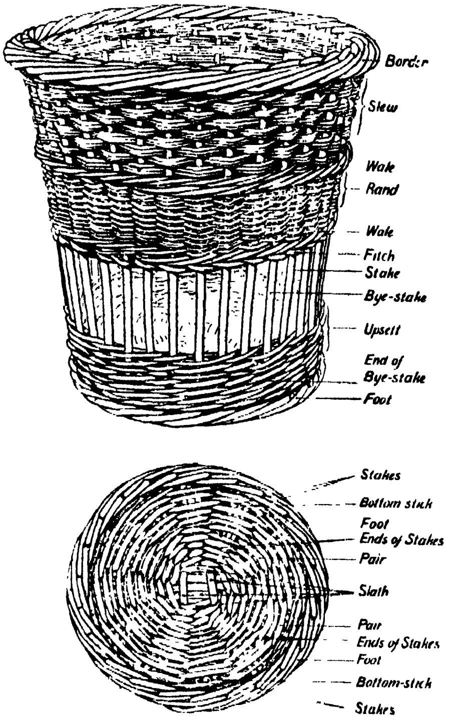
3. SCREW BLOCK

The Bottom. The first part to be made is the bottom. Cut the butts from, say, six rods, of nearly equal thickness, and the same length, but rather longer than the diameter required. Cross three over three at right angles, slicing a little at the centre where they cross, to let them lie neatly. Prepare two rods, called *slath rods*, and sharpen the ends. The crossed sticks are on the plank, and, pressing them down with the foot, you thrust the sharp end of the first slath rod in at the crossing, bend it round the three ends pointing away up over the sticks to the right, down round the sticks directed towards you, and up on those to the left. At the same time we are working the other slath rod in an opposite direction, crossing them over one another, binding the whole in one, and forming what is called the *slath*.

The same method is pursued in making the body of the bottom, with a difference. The slath rods have been worked as a pair—that is, two worked alternately over one another—but the bottom sticks have been treated as four units of three. But as soon as the slath has been firmly tied, we begin to open out the sticks, passing the weaving pair in between each, widening them out further and further, so as to form them into radii of a circle the size of the bottom of the proposed basket. When the size is reached, the surplusage of bottom sticks is cut off.

Upsetting. We have now to see about making the sides of the basket. First select an odd number of rods, or stakes, say 23, if the sides are to be *slewed;* an even number, say 24, if they are to be *randed* or *fitched*. With the shop knife make long points on the stakes by cutting into the backs, and insert by the sides of the bottom sticks. Having driven the sticks well in, prick each one up with the point of the knife. The upper ends of the stakes will be flying loose, and to keep them in position a hoop about the size of the head of the basket designed should be made and put round the upright stakes, holding them up in position. Now drive them in evenly all round with the iron.

The *upset* we now propose making is done by the stroke named the *wale*. This gives a good basis to the basket. Selecting three rods as nearly alike as possible, we weave them alternately one over the other, and in their intertwining enclose the stakes. If the basket is to be *footed*, begin with the tops and piece in three other rods when the butts are worked out. If not footed, begin with the butts, which are sliped and inserted in sequence alongside three following stakes.



4. THE PARTS OF A BASKET

Filling. The upset made firm, we may fill up the sides with any or all of the strokes we have mentioned. Suppose it is an open skeleton-sided basket that we have to make. In this case we use the fitch, and bye-stakes are inserted in the upset between the pairs of stakes. This stroke comes as near to simple twining as it is possible to imagine. We begin with two rods; for short lengths, a single rod is doubled and twined. On the round basket, however, it is better to use two. Rod No. 1 begins behind stake No. 1, and comes round in front of stake No. 2; rod No. 2 begins behind stake No. 2 and twines with rod No. 1 as it comes round to pass in front. The one is always passing *under* the other, not above, as in the pair. Two or more fitches are required, according to the depth of the basket, which may be strengthened by a wale above each.

Now we want a strong binding course for the top of our basket, and resort is again made to the wale. If working with three rods, weave them over two stakes and behind one alternately, while making each follow and weave over the other in regular succession. The stakes are then laid down and woven behind and in front of each other to form a border.

Randing and Slewing. Randing is at once the simplest and most effective weaving. Like plain weaving of cloth, it is the foundation of all other styles. From this it will be inferred that the stroke is simply one rod over and under one stake alternately. Select a rod, put the butt behind a stake, the length of the rod extending to the right, and with a jerk of the finger and thumb draw it in front of the next stake; then jerk it back behind the next stake. In this simple style weave as much of the side as is necessary.

The quick filler is the *slew*. With this stroke, an expert worker could fill up the sides of a basket in a very short time. The best way for a learner is to start with one rod and gather up to three in the following way: Put one rod in and carry it round a stake or two; put in another to run alongside; add the third; then carry the slewing right round, always adding on a rod as one comes to an end. This is the method used in the construction of the coarser kinds of basket-work, such as packing.

The stakes are longer than the sides require by a good deal. With the picking-knife prick each stake on the right side, and bend over from left to right, so as to come close over the last round of weaving Pass each successive stake under the bend of the one before it, and then carry forward over a proportion of stakes, according to the number available and the thickness of the border desired. In passing along the stakes add to the thickness of the outside breadth; when brought round to the inside again, they add to the breadth of the inside. Thus the stakes are twined into an equal border. The protruding ends are cut off by the picking knife.

The foot, when needed, is worked in similar fashion. The tops cut from the stakes, after the border has been formed, are inserted beside the upsetted stakes. Having been thus fixed, two rounds of waling are added and the foot rods are laid down and worked into an ordinary border.

The lid is generally made like the bottom. Many and complicated methods of handling are practised. The simpler form is to top a rod and sharpen the butt, which is inserted alongside a stake. The rod is then twisted, looped under the border and roped over itself three times, resembling a three-stranded rope.

CYCLOPÆDIA OF SHOPKEEPING

SURGICAL INSTRUMENT DEALERS. Surgeons' and Nurses' Requirements. Elastic Hosiery and Measurements. Other Surgical Apparatus
SWEET-SELLERS. A Sphere for Women. The Stock. Expenses and Profits. Sugar Confectionery

Continued from page 5346

SURGICAL INSTRUMENT DEALERS

The sale of surgical appliances can hardly be made into a separate business unless under exceptional circumstances, and in large cities. As a rule, the sections dealt with in the following article are combined with other businesses, such as a chemist and druggist, or herbalist. Some sections are more suited for certain districts, the most important being those dealing with the supply of elastic hosiery and trusses. These are departments of a chemist's business which are often much neglected. The stock required is not large, but it is necessary to have a lady assistant for fitting on ladies' surgical appliances. Often the chemist's wife is available for this purpose, but both qualified and unqualified women chemists are now readily obtainable.

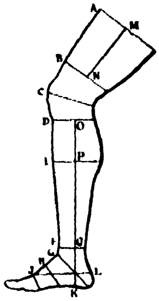
Surgeons' Requirements. These are very numerous, but we have space to refer to them only in general terms. In the first place, sets of operating instruments cost about 12 guineas, but a case of instruments for minor operations, costing about £10, is generally the armamentarium of the general practitioner. Pocket dressing sets cost 30s. to 42s., and are carried by most surgeons. Stethoscopes cost from 2s. 6d. each to 10s. or 15s. for the binaural pattern. Vaccination cases to meet the Local Government requirements cost 15s., although many surgeons content themselves with a lancet and vaccine points without having a special case. Splints are necessarily stocked by those who supply surgeons; these cost from 2s. a set of Gooche's to 4s. 6d. a set of Cline's or Pott's. Pemberton's hand splints cost 4s. 6d. a pair. Fracture-cradles are often let out on hire; they cost from 7s. 6d. to 21s. each, and are charged 2s. 6d. to 5s. for hire. Catheters and bougies and various kinds of syringes are in constant request. Forceps, knives, speculums, and drainage tubes may be mentioned, each of these classes being made in great variety, each for special purposes. Instruments for the ear, eye, mouth, throat, and teeth exist in bewildering variety.

Nursing Requisites. Nurses' chatelaines, to contain such instruments as forceps, spatulas, and clinical thermometers, sell at 15s. complete. Clinical thermometers cost from 12s. a dozen, with lens front 20s. a dozen, and sell at 2s. 0d. to 3s. 6d. If a Kew certificate is supplied, the charge is 1s. 6d. each extra. Bed-pans are either circular or slipper-shaped, and cost—round, 2s. 6d. to 3s. 6d.; slipper, 3s. to 6s. These prices are for earthenware, but for hospital use enamelled iron or block tin pans are demanded. Earthenware urinals cost from 1s. 6d. each; the shapes are known as spoonbill, upright, and coach. Many kinds of brushes are required by nurses for applying pigments to the body. Small camel-hair brushes are designated crow, duck, goose, and swan, according to size. Feeding-cups are made in earthenware and glass, the former being in greatest demand and costing from 10s. a dozen. Earthenware inhalers cost about 2s. 6d. each, and sell at 3s. to 4s. Chest-protectors are much required as the winter season approaches. These are made in scarlet or white felt, pine felt, or rabbit skin. When the protectors cover the back as well as the chest, they are known as lung-protectors. The sizes run from No. 0 to 6, No. 4 being the favourite size. A No. 0 chest-protector measures about 7 in. by 8 in.: a No. 6, 14 in. by 16 in. Spitting-cups are necessary for bronchial patients; the cups cost from 5s. a dozen, but the kind costing 7s. or 8s. a dozen are most usually sold. Bronchitis-kettles sell at 1s. 9d. to 4s. 6d., and cost from 1s. to 2s. 6d., according to size. Bed-baths are less frequently required; they are in form like a slipper bed-pan, but made of tin and deeper. Medicine droppers, tumblers, and spoons are other nursing conveniences that should be mentioned here.

Bandages and Dressings. In this section must first be mentioned lint, cotton-wool, and bandages. Lint, such as is used for surgical dressing, costs 1s. 4d. per lb., but if really made of linen it is more expensive, but hardly worth the extra amount. Cotton-wool in the cheapest qualities costs 8d. per lb., but a pure white absorbent wool, costing 1s. 9d. per lb., is most in demand. The lint and wool are also supplied medicated with sal alembroth, carbolic acid, boric acid, etc., lint thus rendered antiseptic costing about 2s. 6d. per lb., cotton-wool 1s. 3d. per lb., while medicated gauze used for covering costs 1s. 6d. per dozen yards. Surgeons' bandages are made of bleached or unbleached calico, gauze, and flannel, the kind known as water dressing being mostly used. These cost from 1s. per dozen 2-in. bandages. The width of bandages depends on the use to which they are to be put, the narrow ones (1 in.) being for the fingers, the broadest (3 in. to 4 in.) for the thighs. In some cases it is preferable to keep the bandages in rolls of 20 in. wide, and cut to other widths with a sharp knife. Esmark's triangular bandages are much in demand when ambulance classes are being held; these bandages cost 6s. a dozen, and sell at 9d. to 1s. Other bandages are plaster of Paris and stockinette; the former are used to give support in fractures of the limbs, and the plaster sets when wetted with water. Martin's rubber bandages are used for varicose veins of the legs; the cost is from 10s. 6d. each, this being for a bandage 21 ft. long, 2½ in. wide. Suspensory bandages are much used by athletes, and for riding; they are made with cotton or silk pouches, and sell at from 1s. to 3s. 6d. each, a bandage selling at 1s. 6d. being most in demand. First-aid dressings are often carried by cyclists and motorists; they sell at 1s. each. Strapping plaster in yards and rolls is needed for surgeons' trade. The favourite is the brown holland adhesive, which costs 6s. a dozen yards.

India-rubber Goods. The uses of india-rubber for surgical appliances are very numerous, chiefly in those cases where impervious articles are desired. Water-proof and air-proof goods are in great demand. Hot-water bottles are perhaps best known; these run in sizes from 6 in. by 8 in. up to 10 in. by 12 in., the former costing 3s. and the latter 6s., and selling at 4s. 6d. to 8s. 6d. Water-cushions and water-beds are larger forms of the water-bottle. Water-beds are generally let out on hire, and a bed 30 in. by 72 in. costs about £5 10s., according to the weight of india-rubber. The hire charge is from 15s. a week, but the bed should not be let out for infectious cases, and in any case must be well washed with carbolic soap when it is returned. Air-pillows, circular; cost about 7s. for a 15 in. size, and 9s. for 18 in.; the reeded pattern, 16 in. by 12 in., 6s. each. Air-beds are often preferred to water-beds on account of their lower cost, an air-bed 24 in. by 72 in. costing about 50s. Ice-bags and ice-caps are in demand, a circular ice-bag 6 in. in diameter selling for 1s. 3d., 12 in. 3s., and costing 9s. and 20s. per dozen respectively. Waterproof sheeting is either single or double, and is 36 in., 60 in., and 72 in. wide. Single sheeting costs 1s. 3d., 2s. 3d., and 2s. 9d. a yard, and sells at 2s., 3s., and 4s. a yard. India-rubber urinals for men and women sell at 12s. to 15s. each, but being not much in demand seldom pay to keep in stock. Enema syringes, douche-cans, injection-bottles, spray-producers, breast-exhausters, nipple-shields, and finger-stalls fall into the class of druggists' sundries usually associated with the business of a chemist and druggist.

Elastic Hosiery. Varicose veins in the legs were formerly always treated by bandaging. Now some form of elastic hosiery is nearly always employed. Not only for varicose veins are elastic goods used, but they are used as supports for the ankle after sprains, and for weakness of the knees. Athletes require them for the arms or legs weakened by excessive strain in football, cricket, shooting, or lawn-tennis. The material from which elastic hosiery is woven by machinery consists of india-rubber threads alternated with threads of cotton, silk, or wool, and the articles are made white, pink, or blue tinted, and sometimes red, drab, or black. The various articles are made to draw on or, less frequently, to lace. The former are more convenient, besides being cheaper. For warmth in cases of rheumatism, elastic hosiery is made with a fleece or pile of wool on the inner surface, this especially applying to knee-caps. The following table gives the kinds of elastic hosiery in common use, tells how to measure the patient, and the cost and retail price of each article. The measure is taken on the naked limb on rising in the morning, and an allowance of one in eight is made for pressure by the stocking maker; the patient must give the exact measure. The prices are approximate as the cost varies considerably with different makers, and it is as well to remember that cheap elastic hosiery is not always cheap in the long run. The makers keep some eight or nine stock sizes, numbered 1 to 8 according to the length, a No. 5 stocking being 16 in. long; while the circumference of stock sizes is indicated by letters, a C stocking being about 10½ in. Dealers will find the plaster legs sold by wholesale druggists' sundriesmen at about 5s. very useful for displaying elastic hosiery. The measurements required for wristlets and elbow supports will be judged from what is required for hosiery.



Belts and Braces. Belts are used as supports for the abdomen. The measure must be taken with great care as the belt should fit like a glove. The best guide is a calico pattern fitted to the body. The fronts are made flat or round, and it is necessary to give the circumference at three places, and the depth both at the back and front. Ladies' abdominal belts sell at 7s. 6d. to 21s. Belts of various kinds are made for gentlemen. The knitted variety is known as a cholera belt; while money belts are often asked for by those going abroad. Chest-expanding braces are needed for women and children; they cost from 4s. to 10s. each.

Trusses. There are four kinds of rupture or hernia for which trusses are required: (1) inguinal, (2) scrotal, (3) femoral, and (4) umbilical. The most common rupture is inguinal (in the groin), and it may be either on the right or left side or both sides, requiring single or double trusses, as the case may be. The common kind of truss consists of a steel spring for encircling the body and a pad for pressing on the rupture, the whole being covered with basil and moleskin. The ordinary sizes are 30 in. to 40 in., 36 in. being the size mostly required. These trusses cost from 16s. to 30s. a dozen single, and 30s. to 50s. a dozen double, and sell at from 2s. 6d. each. Other kinds are the Moc-main, S. and O., and Coles pattern. The Moc-main have no springs and are suited for patients who do not have heavy labour to perform. This pattern truss costs 8s. single, and 15s. double, and sells at 12s. 6d. and 21s. In measuring for a truss, a tape measure is used. It is passed round the hips, and the number of inches indicated is the size of truss required. The truss is put on while the patient is laying down. For bathing, trusses are covered with india-rubber, and the pads of the ordinary trusses are made of various materials, such as wood, ivory, or celluloid, and in some cases the pad is filled with glycerin. The scrotal truss has a triangular pad which goes between the legs. The sizes run the same as the inguinal trusses, but they are more expensive, single trusses costing from 4s. each and double trusses 7s. each, selling at from 7s. 6d. each. Femoral trusses for rupture situated in the thigh differ from the inguinal truss in the size and form of the pad and the direction of the thrust. There are two general forms of femoral truss, known as circular and half-spring. The circular form costs from 2s. 6d. each single, and 4s. each double, and sell at 5s. and 8s. each; while the half-spring pattern costs 6s. and 12s. each, the retail price being 8s. and 17s. 6d. each.

Description.	Measures required.		Cost per pair.		Sell at per pair.	
	Circumference at	Length at	Silk.	Cotton.	Silk.	Cotton.

Thigh knee-cap	A, B, C, D	A to B, B to C, C to D	11/- to 13/6	6/6 to 8/6	15/- to 18/-	9/- to 10/6

Umbilical rupture occurs in both young children and old persons. Trusses are made for this form of rupture, but the india-rubber or web belts are much better, an air-pad being arranged to press the navel back into its place. The sizes for children are 12 in. to 20 in., costing 1s. 6d. to 2s. each, and retailing at 2s. 6d. to 3s. Another kind of truss—the rectal truss—is needed occasionally for prolapsus ani, such an instrument selling at one-and-a-half guineas, and costing about 20s.

Artificial Limbs and Orthopædic Appliances. The measurement for artificial limbs is a matter of comparison with the size of the corresponding limb. Needless to say, the utmost care has to be taken with the measurements. An artificial leg for amputation above the knee sells at £10 to £15; an artificial arm and hand at about £15. Artificial hands cost from 20s. to 70s. each. Crutches cost from 36s. a doz. pairs, better kinds costing 4s. 6d. to 40s. a pair. Leg-irons for deformed legs sell at four to six guineas. Poroplastic jackets for spinal support cost from 18s. each, the more elaborate Sayre's apparatus costing £5 to £6.

Deafness Appliances. Deaf people require ear-trumpets and conversation tubes. Ear-trumpets in bronzed tin sell at 4s. 6d. to 6s., the telescope form from 7s. 6d. to 12s. Ear-cornets or resonators are a smaller form; they are made bell or egg-shaped. Vulcanite trumpets sell at 5s. to 7s. 6d. Conversation tubes 3 ft. long cost 2s. 6d., and sell at 4s.; but more expensive ones are sold which have ebony mounts and silk-covered tubes. Acoustic fans and audiphones are refinements of hearing apparatus, and sell at from two to three guineas.

SWEET-SELLERS

There is no retail establishment more universally popular than the sweet-shop. Old and young—particularly the young—rich and poor, have the "sweet tooth." It is not surprising, therefore, that shops for the vending of sweetstuffs abound in every district; and the status of the neighbourhood may often be gauged by the appearance of these establishments, and the kind and quality of goods sold therein. It is an enticing trade for people with small capital, for little or no experience is required in learning the business. It is a trade in which, given normal conditions, the cleanly, careful, polite and attentive person is bound to succeed. But it must not be entered haphazard, for there is keen competition in this, as in all other trading concerns nowadays. The grocer, the chemist, the restaurant and the stores all vend sweets of various kinds, and each may be reckoned as a competitor, in some measure at least, to the legitimate sweet-seller. But for a man in delicate health, for a woman who has been "stranded" and does not quite know where to turn in order to gain a livelihood, for a widow, or even for a married woman, who essays to supplement her husband's precarious earnings, the selling of sweets offers a comparatively easy outlet for business energy and enterprise.

Gaining the Necessary Knowledge. The practical confectioner needs no teaching, so that in this article we shall deal only with the sweet-selling novice. It is advisable that, before starting, the beginner—who more often than not is a woman—should get a little practical experience in the treatment of sweets. This may best be obtained in the wholesale depôt of some large manufacturer of good reputation. Such manufacturers are only too willing to give a novice, who is also a potential customer, the benefit of their experience. A week or so in such a depôt will serve to initiate the intelligent pupil into the mysteries of the storage and manipulation of sweets. She will learn very quickly what kinds of goods deteriorate most quickly, how to prevent deterioration, and what to do when the goods show symptoms of becoming stale. It will be impressed upon her that sweets that may have "caught the sun" or have become damp should be made into a "mixture" with other and fresher goods, and sold as quickly as possible at slightly lower prices. Above all things it should be remembered that some showing signs of age should be cleared out at once even at a sacrifice of profit; although the best class of chocolates, on the other hand, mature with keeping. Careful storage, cleanliness, politeness, and fresh sweets make a combination that the public will find irresistible.

The Money and the Shop. If the beginner has about £50 capital she may make a very creditable start. Of course, this is a small amount, and the beginning would be humble. A good middle-class neighbourhood, and a small shop with living-rooms attached, would be selected by the young wife or spinster with ambition, taste, and the capital named. The rent in a middle-class suburb would not be great, provided the main street be not selected for the scene of operations. The fittings required for the shop may be quite modest, and need cost next to nothing. A handy husband or male friend could fit up and stain a few shelves around the shop and in the window. A counter, a pair of scales, weights, a scoop, and a gross or two of paper bags of different sizes would not cost more than a few pounds. Neatness, brightness, and, above all, cleanliness, are essential, but the clever woman would find it little trouble to adorn the shelves with fancy paper or other drapery, and so make the place attractive. If feasible, a few glass shelves raised on blocks for the window may be obtained at a small cost, as well as a dozen show-bottles of different sizes, costing an average of 1s. each. Receptacles for the goods are not really necessary, for the manufacturers send out their productions in good bottles and other containers, with attractive labels. These bottles are charged for when sent out, but the charge is credited when the bottles are returned empty. Some manufacturers even supply ornamental cases and dainty show-bottles free on loan to advertise their wares.

Arrangement, Methods and Display. On no consideration need there be a large opening stock. Attraction is the great thing, and taste in window display is the most trustworthy magnet. Small quantities and much variety should be the rule, for in nothing is the public taste so peculiar and varied as in sweets. Therefore, give the public variety, and never let the window be too great a trouble. Let the stock be carefully watched and arranged so that the old is got rid of before the new is begun upon. If in a busy thoroughfare, near a railway station, theatre, or place of amusement, it is essential that packets of sweets be always kept ready to be picked up, for travellers and amusement seekers have not usually much time to waste in fastidious selection. But the chance customer, in the majority of cases, does not make the business. In the environment that we have indicated for our beginner, a family trade should be aimed at. Although apparently a transient business, the sound sweetstuff trade is really not so. It is kept up by regular customers, just as other businesses are, so that the influence of a pleasant and attractive personality, a bright shop, a fresh and tempting display, and genuine—not cheap—goods cannot be sufficiently emphasised. An endeavour should be made by issuing leaflets, displaying special lines, and so forth, to secure a reputation for selling better caramels, or chocolates, or fondants, or what not, at the same price as competitors. This reputation once established, people will go a long way to get your particular speciality, and they should be made to feel that you are glad to see them. Daintiness—that peculiar attribute of womankind—is even more essential than painful neatness and rigid cleanliness. It is not always necessary to show full packets of sweets, for many manufacturers supply good customers with dummies, and there are plenty of artistic showcards to be obtained free of charge from manufacturers to enliven any spare wall space there may be. Only stock reliable goods, and sell at a fair profit; the "cheap and nasty" trade is not worth the candle.

The First Stock. An expenditure of about £20 would make quite a nice opening display. The aspiring sweet-seller would go, or send, to the showrooms of some reputable manufacturers of general confectionery (like Clarke, Nicholls & Coombs, Ltd., of London, for instance), and select as judiciously as possible a varied stock somewhat on the following lines. In chocolates, order four 2 lb. boxes to sell at 1d. an oz. (cost about 9d. per lb.), two boxes to retail at 1½d. an oz. (1s. per lb. cost), and two boxes at 2d. an oz. (1s. 6d. wholesale). Fancy boxes and baskets should be bought very sparingly at first until the requirements of the neighbourhood are known, and care should be exercised in the purchase of these to make sure that the "turnout" can be sold without loss—that is to say, that a "¼ lb. box" actually contains ¼ lb. of chocolates, and so on. Then select a few of the smallest-sized boxes of popular lines of goods to retail at 6d., 3d., 1d., and ½d. per packet. The cost of such goods is usually 4s. 6d. per gross for halfpenny goods, 8s. 6d. per gross for penny articles, 2s. 3d. per dozen for threepenny goods, and 4s. 6d. per dozen for sixpenny packets. Marzipan selections would be purchased in 2-lb. or 4-lb. boxes in qualities to retail at 1d., 1½d.. and 2d. per oz. Then mixtures packed in rows, and loose, other than marzipans will be needed to retail at from 2 oz. for 1½d. to 1½d. per oz. At prices under 2 oz. for 1½d. there are other lines such as gums, fruit pastilles, glacé and crystallised, to be thought of. Then there are popular lines of goods including coco-nut specialities, fondants, dragées and gums to sell at 2 oz. for 1d. For about 21s. ½ cwt. assorted would be secured in bulk. Caramels are perhaps the most popular sweets of all. They may be ordered in 1d., 2d., 3d., 6d., or 1s. packets or loose in 2-lb. or 4-lb. boxes. At least two 2-lb. boxes of approved brands (costing about 9d. per lb.) should be secured. After that ¼ cwt. of boiled drops, toffees, satinettes, fourrés, etc, should be ordered in 2-lb. bottles. These retail from 2 oz. for 1d. to 1d. per oz. Cachous might be obtained in ½-lb. or 1-lb. bottles, but great care should be taken with these. They must be kept dry and in airtight containers, to prevent deterioration, as they are not quick sellers. The retail prices range from 2 oz. for 1d. to 2s. 6d. per lb.; the best qualities retail readily at from 4d. to 6d. per oz. Lastly, a few 4-lb. boxes of lozenges—peppermint, musk, heliotrope, etc.—the products of different makers, would be necessary to complete the stock. It is invariably safe to buy Cadbury's and Fry's chocolates, Rowntree's chocolates and gum[illegible] Mackintosh's toffee, Clarnico marzipan selections, caramels and fondants, "My Queen," chocolate nougat and penny marzipans, Peter's and Cailler's Swiss chocolates, and "Devona." These makers have obtained a reputation for the particular kinds of goods named, and there is a public demand for them all over the country.

Making Sweets. In these days of large manufacturers, with up-to-date machinery, it would be ridiculous for the untrained sweet-seller to attempt to make her own goods. If care be taken to deal only with reputable houses, and in approved brands, it will be found much the more profitable and satisfactory method to buy everything from the wholesaler. But some extra-ambitious beginner may have an idea that manufacturing one or two special lines in a small way brings extra credit to the venture. Experience has certainly shown that in some instances kudos is gained by a sweet-seller making a particular toffee or cream of his or her own; but the particular sweetmeat must have some distinction to make it worth the trouble from a pecuniary point of view. If, however, manufacturing is decided upon, a small outfit, costing in all about £5, would include a stove-top, a copper saucepan (to boil 10 lb. or 12 lb. of sugar at a time, a tin frame to pour the toffee into (say, 15 in. long by 10 in. wide and 1 in. deep), a smooth cast-iron pouring plate (3 ft. by 1 ft. 8 in.), for rocks, drops, and hand-cut goods, a pair of scissors and a thermometer. The plate would be fixed on a small table or rough bench, about 2½ ft. high, and there might also be a 3¼ in. strong frame and two pairs of rollers to fit.

Sugar Boiling. The process of sugar boiling at different degrees has first to be learned. There are six degrees in sugar boiling, known as the "smooth" (approximately 215° F. by thermometer), the "thread" (230° F.), the "blow" or "feather" (235°F.), the "ball" (240° F.), the "crack" (252° F.), and the "caramel" (260° F.). The "smooth" is tested practically by boiling, for instance, 7 lb. of loaf sugar in 3 pints of water for about 10 minutes after the sugar is all dissolved. Then, if the handle of a teaspoon be dipped, and the boiled sugar drawn between the forefinger and the thumb, and on working it feels slippery, the first or "smooth" degree has been attained. A little longer boiling, and the same test repeated until a thread-like appearance is noted, indicates the second degree. Continued boiling and consequent evaporation gives the "blow" or "feather" stage, which is tested by dipping a skimmer or slice with holes in it into the boil, draining off, and blowing hard through them, until feathery particles pass away. The "ball" stage is only a little in advance of the last, and is known by dipping the boiled sugar on the spoon in cold water and then working with the forefinger and thumb as before. If it is tough, and works like a ball of hot bread, it is at the right stage. When the "crack" degree is reached, and the same test as for "ball" is applied, it will crack. Or if slipped off quickly from the spoon and bitten, the sugar crunches and leaves the teeth without sticking to them. This is, perhaps, the most useful degree in sugar boiling. For the caramel stage, the boiling is continued, and the sugar is watched carefully until it changes colour. The novice will spoil many batches at first, for only practice makes perfect. The foregoing is merely for the guidance of any beginner desiring to experiment, for the business of sugar boiling cannot be taught by books. Moreover, as stated before, it would scarcely be worth the sweet-seller's while. But having gone so far, it might be well to explain how one or two confections are made.

Toffee and Creams. Everton toffee, for instance, varies with different makers; but one of the best methods of making it on a small scale is by boiling 7 lb. of best raw sugar in 3½ pints of water until 245° F. is reached on the thermometer—that is, a stage between the "ball" and the "crack." Then add to the boil 1 lb. of fresh butter, boil the whole nearly to the "crack" over a slow fire, add one teaspoonful of essence of lemon, and pour into the frame. For special purposes, 4 oz. to 8 oz. more butter may be used. Any variety of the soft, rich candies, popularly known as "creams," can be made by boiling together 7 lb. refined sugar, ¼ oz. cream of tartar, and 3 pints of water, to "thread" degree; then take it from the heat and set aside for half an hour. At the end of that time work the syrup with a spatula, or a palette knife, against the sides of the pan until it changes into a thick, creamy-looking substance. When that condition is obtained, mix into it any kind of fruit essence, or fruit preserves, almonds, marmalades, etc., according to the particular variety of "cream" desired. Lastly, put into tin frames or shapes (previously well smeared with salad oil) to set; cut, and turn out when cold. The object of the cream of tartar is to "cut the grain," or prevent re-crystallisation of the sugar. For in the process of sugar boiling the sugar exhibits a strong tendency to crystallise back into its original form, and it will do so when boiled beyond "feather" unless the process is retarded by an acid which prevents the particles being held together by what is known as the "attraction of cohesion." The safest and most trustworthy preventive of this is cream of tartar, in the proportion of not less than ¼ oz. to 7 lb. of sugar.

Expansion. Assuming that the business is growing, and returning a profit, there are many ways in which enterprise may be shown. The fittings may be gradually added to, and show-cases and sweet-stands bought to increase the embellishments of the shop. In this connection, some useful information may be obtained by consulting the articles on Bakers and Confectioners, beginning on page 930 of this section. The stock, of course, would gradually be increased in certain lines as the needs of the neighbourhood are known, but a constant endeavour at a high standard of taste should be made. There is fashion in confectionery as in all else. During recent years, chocolates and caramels of all kinds and shapes have been the rage. Then, the business is affected by the seasons of the year. In spring and summer acid drops and sweets flavoured with the natural juices of fruits are in demand. In the late autumn and winter, nut sweets are asked for, while warming confections, such as those flavoured with ginger or cloves are the thing for cold weather. At Christmas, bon-bons, crackers, Santa Claus stockings, tiny Christmas hampers of chocolates, sugar animals, and so forth, are expected. Easter is a good time for all kinds of white sweets, such as white sugar almonds, white creams, etc., not to mention Easter eggs, which then form nine-tenths of the trade. Aerated waters and ice-cream are appropriate side lines for the sweet-seller, provided there is room for customers to sit down and consume these things. Aerated waters show a good profit, and should be kept in syphons as well as in bottles.

Ice-cream. The ice-cream business, if it can be properly worked, is a very lucrative side line. All that is needed is a freezing machine, made of pewter (which would cost not more than 30s.), a strong wooden tub (large enough to hold the freezer and to admit of the packing of the freezing materials between the sides of the tub and the freezer), and a pewter spatula, or scoop, with a long wooden handle. The mixture to be frozen is poured into the freezer, which is placed in the tub, and the space between filled with broken pieces of ice, and from 2 lb. to 3 lb. of coarse salt. The handle is then turned until the spatula stands upright in the mixture, care being taken during the freezing process to dislodge the "custard" as it thickens from the sides of the freezer with the spatula, so that it may be intimately mixed. The ice-cream "custard" is usually made by whisking four fresh eggs, putting them, with a quart of new milk, ½ lb. of loaf sugar, and 1 oz. of fresh butter, into a pan, whisking the whole together and heating over a slow fire, stirring all the while, until the mixture comes to a boil, when it begins to get thick. Then lift off, strain through a fine horse-hair sieve, or muslin, let it stand till cold, freeze, flavouring with vanilla, and tinging the mixture slightly with saffron to give a "rich" appearance. There are many variants of this recipe, and different flavourings and colourings may be employed, such as raspberry, strawberry, and lemon. Excellent ice-creams are sold ready-made to hotels and shops in small freezers holding about a quart; but care should be taken in such cases to deal only with firms of good repute. It may be that the business increases to such an extent that a pedestal fountain, for the ready production of aerated water, and even the elaborate soda fountain now in vogue, and so popular in America, are looked upon as necessities to supply the wants of the neighbourhood, but that stage of progress would not be reached for some years.

Turnover and Profit. A confectioner must have a good profit, for a variety of reasons. First of all, the hours of business are long, therefore lighting bills are large and attendance is protracted. Moreover, the goods are perishable, and at least 10 per cent. must be allowed all over for deterioration. This is a problem that should be faced boldly from the start, for nothing is more fatal to a business than a reputation for selling stale goods. Therefore, one must be prepared for a 10 per cent. sacrifice on the general turnover. The stock should be turned over at least once a month. The rate of profit on packet goods ranges from 25 to 33 per cent., but on some goods 50 to 75 per cent. on the turnover is no uncommon thing. There is naturally a greater proportional profit on the higher-priced goods, but they have not such a quick turnover. At first, manufacturers or wholesalers would have to be paid cash, but as the business becomes established, a month's credit would be given. The usual trade terms are one month net, but some manufacturers give 1¼ per cent. discount at a month or even considerably more to good customers. Whether a discount is given or not the net charge varies but very little, if at all, among the best firms. Manufacturers are always, of course, willing to aid deserving traders either by longer discounts, or by special prices on special quantities, whenever circumstances warrant such departures from the usual practice. The retail trade is essentially for cash, and this enables the shopkeeper to see how things are going day by day, and to expand or to retrench, as occasion arises. There need be no fear of failure if the trader keep a sharp eye on the condition and requirements of the stock, if she own a dainty and attractive establishment, and if she avoid the brusque and haughty manner, or the careless and slovenly style in dealing with the public.

PLASTERING

The Plasterer's Tools and Their Uses. Materials in Plastering. Applying the Plaster. Cornices and Ornamental Work

By Professor R. ELSEY SMITH

THE plasterer's work consists of covering rough and uneven surfaces with a plastic material so as to produce a smooth, hard surface, which may be treated decoratively by covering it with paper or with colour, or which, instead of being finished as a plain surface, may be modelled in relief as a means of decoration.

Plasterer's Tools. The tools used by the plasterer are somewhat numerous, several varieties of some kinds of tools being required in a complete outfit.

A square stand or stance [**1**] is formed with four legs and with top rails flush with the top of the legs framed all round; a lower set of rails a few inches from the bottom of the legs is required for stiffness, and on these a platform of boards may be formed. This supports the *gauge-board*, on which materials are mixed, which is separate from the stance, and which is usually about 3 ft. 6 in. sq. and ¾ in. thick; it has two cross pieces at the back and a diagonal piece between them to keep the boards from warping. For gauging concrete these are made about 9 ft. square and 1 in. thick, in two halves, or a temporary platform of scaffold boards is sometimes used.

Brushes [**2**] for the best quality of work are made of hogs' bristles tied to wooden handles. The stock brush is sometimes made plain and broad; at others, tied up into three or four tufts side by side. Cheaper brushes are made with grass fibre. *Tool brushes* [**3**] are circular. *Brooms* are made of split whalebone or of wire for keying plaster, etc. *Large compasses* [**4**] of iron are required, and *calipers* [**5**] for taking the diameter of convex and concave objects.

Drags [**6**] are thin steel plates with toothed edges, and vary in size and form.

Floats and Rules. *Rules* and *floats* of various forms and sizes are employed, and should be made of well-seasoned pine, free from knots. The *Darby* [**7**] has a blade about 3 ft. 6 in. long and 4 in. or 5 in. wide, and has two handles screwed to the back; it is used for floating bays between screeds. A *floating rule* [**9**] varies from 8 ft. to 20 ft. long, and from 4 in. to 7 in. wide. The back is tapered towards each end; it is used for forming screeds and for forming surfaces between the screeds. A *traversing rule* is a similar rule about 6 ft. long, used for forming screeds in gauged stuff or setting stuff.

A *feather-edge rule* [**10**] may be made of any requisite size, generally about 5 ft. long and 5 in. wide; it is about 1 in. thick, one edge being splayed to about $\frac{1}{16}$ in. thick. It is used for working and cleaning out angles.

A *gauge rule* [**8**] is like a straightedge, but has a notch or sinking formed at one or both ends. The double gauge rule is used for forming sunk surfaces, the single gauge for forming raised surfaces. A *parallel rule* is used for levelling and setting out parallel lines; it is made of various sizes, and has its two edges exactly parallel. A *levelling rule* [**12**] is made by fixing a wood fillet above the lower edge of a long parallel rule, on which a level may be placed for levelling soffits. The *plumb rule* [**13**] is similar to that used by bricklayers. *Running rules* are strips of wood about 2½ in. by ½ in., planed all round, and of various lengths, and are fixed to form guides for running moulds.

Screed rules vary in size, usually 2½ in. by 1 in., and are used as screeds when laying concrete.

The *concrete float* [**11**] is similar to a parallel rule, about 6 in. by 1 in., varies in length, and has two hand holes cut in it to facilitate its use.

Hand floats [**14**] also are in great variety. They are mostly formed in yellow pine, except panel and mastic floats. The ordinary hand float is about 10½ in. by 4½ in., and ¾ in. thick, with a handle at the back. The *cross-grain float* [**15**] is similar, but a trifle longer and thicker, and cut with the grain across the float, and is formed with a dovetailed groove at the back, into which a hardwood key, carrying the handle, is inserted, which keeps the wood from warping. This is used for scouring the setting coat. A *skimming float* is similar to a hand float, but 12 in. to 14 in. long, and ½ in. thick, and is used for laying the setting stuff. *Panel floats* are usually of beech or pear wood about 6 in. by 3 in., and ½ in. thick. They are used for laying and smoothing gauged stuff in panels and for mastic. *Fining floats* are small floats from ⅛ in. to ¼ in. thick, for working mitres in cornices, panels, etc.

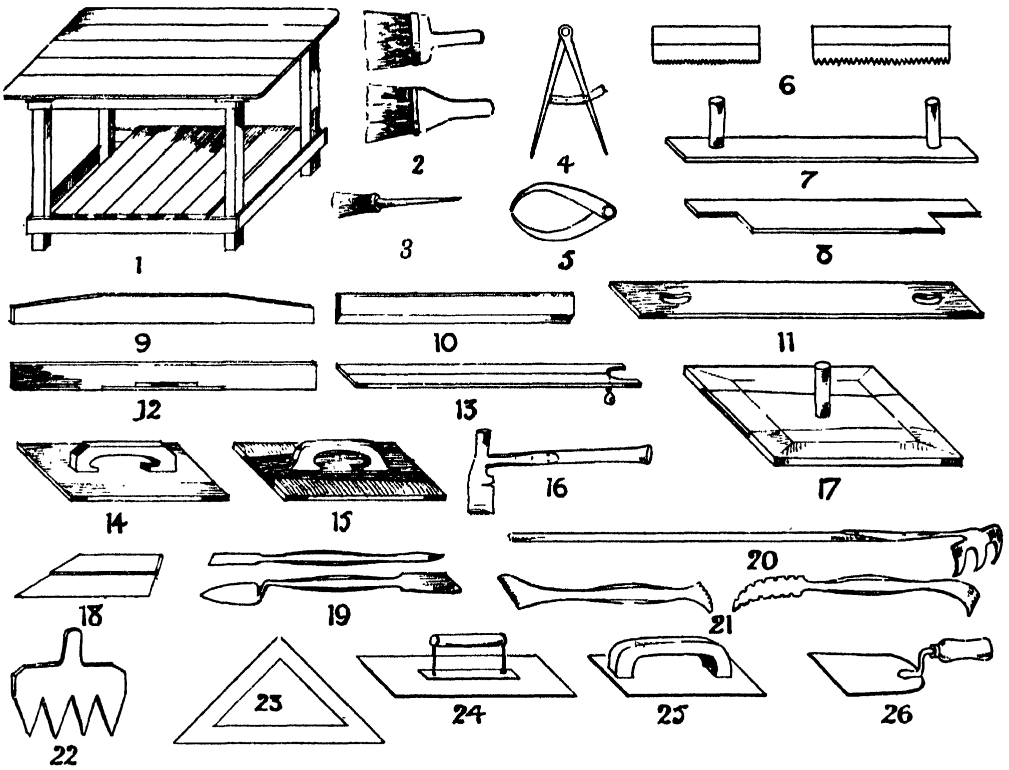
Other Tools. The *plasterer's hammer* [**16**] has a wood handle, with a steel head, one end formed like a hatchet, with a nick in the lower edge for extracting nails. This hammer is used for fixing lathing; the driving end is indented.

The *hawk* [**17**] is a piece of pine about 11 in. or 12 in. square and ⅝ in. thick. The sides are splayed at the back to about ⅜ in. thickness at the edge; a dovetailed groove is formed in the back, into which a hardwood strip, on which the handle is mounted, can be inserted. The board is cut into two halves down the centre of the groove, and hinged together for packing, and in use the strip with the handle is inserted, and keeps the two halves rigid. The board is used for holding stuff and for gauging small portions.

Joint rules [**18**] are usually made of a strip of steel 3 in. or 4 in. wide, and ⅛ in. thick, mounted in a hardwood stock. One end is cut to an acute angle, and this end and the edge are splayed so as to give a fine edge.

A *larry* or *drag* [**20**] is a three-pronged rake with a long, wooden handle, for mixing hair with coarse stuff. *Mitring tools* [**19**] are of various sizes and shapes, and are of wrought iron or steel; they are usually from 7 in. to 11 in. long, with a central shaft, octagonal in form and rather thick, and blades at each end. They are used for mitring and for moulding and cleaning out and stopping ornaments.

Scratch tools [**21**] are made in a similar manner, with a shaft and a tool at each end, and take various forms, and are used for carving, mitres of mouldings and cleaning up enrichments, and for modelling and cleaning models. *Plaster small tools* resemble mitring tools, and are usually made from brass rods, the ends beaten flat and filed to the required shape, and



PLASTERER'S TOOLS

1. Square stand **2.** Plasterers' brushes **3.** Tool brush **4.** Compasses **5.** Calipers **6.** Drags **7.** Darby **8.** Gauge rule **9.** Floating rule **10.** Feather-edge rule **11.** Concrete float **12.** Levelling rule **13.** Plumb rule **14.** Hand float **15.** Cross grain float **16.** Plasterer's hammer **17.** Hawk. **18.** Joint rule **19.** Mitring tools **20.** Larry or drag **21.** Scratch tools **22.** Scratch **23.** Square **24.** Laying trowel **25.** Panel trowel **26.** Margin trowel.

the central barrel filed to octagonal form. This is sometimes bound with waxed thread. They are used in shop work for cleaning up plaster-work.

Planes similar to a carpenter's plane are used for levelling and smoothing plaster surfaces. The blades are toothed.

The *scratch* [22] may be cut out of a ½-in. pine board, and is about 14 in. long and 7 in. broad. One end is shaped, the other cut into teeth about 3 in. long, and the points 1¼ in. apart. An effective scratch may be formed with four laths fixed side by side, and pointed, and is used for scoring floated surfaces to provide a key for the next coat.

Sieves, or *riddles,* of various sizes and degrees of fineness, are made and are used for running lime and washing sand.

Squares, of wood or iron [23], are triangles having one angle a right angle, the other two angles generally being 45°.

Trowels, Etc. *Trowels* are also required of various shapes and sizes for different classes of work. The *laying trowel* [24] is a rectangular sheet of flexible steel, about 10½ in. by 5 in., with a handle riveted to it, sometimes with a single, sometimes with a double shank. The *panel trowel* is similar, but the blade is very springy, and about 5 in. by 3 in. It is used for setting small panels. The *gauging trowel* is made in various sizes, and resembles a bricklayer's trowel in form. It is used for gauging small portions of stuff on the hawk, and for laying stuff on mouldings, niches, stopping small holes in the plaster, and similar work. The *laying gauging trowel* is similar in shape, but larger, from 7 in. to 9 in. long, and tapering from about 3½ in. to 1½ in.; it is used for laying gauged stuff. The *margin trowel* [26] is somewhat similar, but the two sides are parallel, and the end square; the blade is about 3½ in. by 2½ in. It is used for laying and polishing margins, styles, and similar work. The *polishing trowel* is usually a partially worn laying trowel, but the edges should be true and parallel.

Tubs to contain water for washing sand and running lime are required, and may be formed by cutting an old spirit cask in half.

In addition to these tools, most of which are special tools, the following are also used by the plasterer:

Files and *rasps,* of different sizes.

Gauges and *chisels* similar to those used for carving wood are required for carving and cleaning-up plaster, cement, etc.

A *hod* somewhat similar to a bricklayer's hod.

Knives of various sorts for trimming enrichments and angles, and for cutting canvas.

Spirit level.

Iron and wood pails.

Saws for cutting running rules and fibrous plaster.

Screen, as used by bricklayers for screening lime and sand.

Materials. *Plaster-of-Paris* is manufactured from gypsum, which is a sulphate of lime, and frequently contains a considerable percentage of carbonate of calcium. The gypsum is got by blasting, and if dirty, the outer portions are cleaned, and may then be treated by one of two processes.

The first is termed *boiling*. For this, the gypsum is first pulverised, then finely ground, and then conveyed to a large open pan or boiler heated by means of flues, and is kept agitated by rakes revolving on a spindle. After about half an hour, a series of small explosions occur, and the process is completed in about three hours, when the gypsum becomes more dense and sand-like. It must then be turned out of the boiler, cooled, and packed. If left too long, it becomes burned, and will set only after a long time, if at all. Plaster thus made is fine, works freely, and is not liable to warp.

The process of *baking* is carried on in a flat kiln or oven, the fuel not being allowed to come into contact with the gypsum. The kiln is heated to redness, charged with the gypsum in lumps, and the heat gradually increased and continued until the whole of the water present is evaporated, generally for about 16 hours. The material is afterwards ground.

Plaster that has been calcined in lumps sets more rapidly than that ground first into powder. Good plaster, if squeezed in the hand before use, should cohere slightly and retain its form when the hand is gently opened; if it all falls to pieces it is a sign that the plaster is injured by damp. Plaster is slightly soluble in water, and cement which contains plaster to a considerable extent must not be exposed in a raw state to the weather. Good plaster should not set with great rapidity, or its manipulation is difficult. The compressive resistance of good plaster gauged with plain water should be about 120 lb. to the square inch., or nearly 8 tons to the superficial foot, and its strength is increased about 25 to 30 per cent. if gauged with lime water.

Limes. The properties and method of preparing limes and cements have been already fully dealt with. [See pages 648 and 1455.]

The method of slaking lime for use in plasterers' work differs from that used for bricklayers' mortar. The lime is completely immersed in water, about $1\frac{1}{2}$ gallons of water being used to the bushel of lime, and the mass is left till completely slaked and then lifted out in pails, passed through a sieve, and run into a pit with sides of brick or boarding. The material must be left for at least three weeks, and a considerably longer period is advantageous. Lime so prepared is used for making *coarse stuff*.

Lime putty is formed in a similar way, but is run through a finer sieve into a pit lined with coarse stuff, and should be left for at least three months, and may be kept for a long time without injury if protected from the air.

Sand for lime plaster should be hard, sharp, gritty, and free from all organic matter. It should not be too fine for coarse stuff and floating coats, and should not be too uniform, containing both coarse and fine particles. Silver sand is used with Portland cement where a light colour and even texture are essential. Sand for plastering is often specified to be washed, and this should always be done, if any impurities are present, to secure good work.

Hair is used as a binding medium, giving tenacity to the material with which it is mixed. It is usually the hair from the back of oxen, and should be long, strong, and free from impurities. It is obtained in a dry state in bags and must be well beaten up with a couple of laths or light sticks to separate the hairs which are found in lumps. Goats' hair is sometimes used, and hair obtained direct from the tanneries makes the best work. Hair must not be mixed with hot lime, which weakens it, and should only be added to stuff just before using.

Substitute for Hair. Manilla fibre cut into lengths of $1\frac{1}{2}$ in. to 2 in. has been tried with satisfactory results as a substitute for hair, also sisal hemp and jute, which are not quite so strong. Sawdust has been used as a substitute for hair, especially as additional aggregate for coarse stuff, and must be used dry and passed through a sieve to eliminate large pieces; it stands the effect of rough weather and frost when used externally. Some kinds of sawdust are apt to stain the stuff, and these must be soaked before use.

Laths are thin strips of wood split or rent from straight grained wood, generally from Baltic or American timber, and are made by hand, the advantage of such laths being that the fibres run continuously, whereas in sawn laths, though the latter are more regular in form, the fibres may be cut across and thus are less strong. Laths are usually made in lengths from 2 ft. 6 in. to 4 ft., but sometimes longer. They are about 1 in. wide in the face; single laths are $\frac{1}{8}$ in. to $\frac{3}{16}$ in. thick; lath and a half, $\frac{3}{16}$ in. to $\frac{1}{4}$ in. thick; double laths, $\frac{1}{4}$ in. to $\frac{3}{8}$ in. thick.

Laths are fixed usually from $\frac{1}{4}$ in. to $\frac{3}{8}$ in. apart, depending on the nature of the plaster. In good work the ends are butted where joints occur over a joist or quarter, and the line of joints should be frequently broken. They are secured with clout-headed nails from $\frac{3}{4}$ in. to $1\frac{1}{4}$ in. long and should be nailed at every bearing; the nails may be wrought, cut, or cast, and are best galvanised, to prevent rusting. When secured to timbers more than 3 in. broad on the face, the latter should have double laths or fillets nailed along the face to avoid interfering with the key of the plaster, which is formed between each pair of laths; this is termed *brandering* or counter lathing. For lathing of half timber work laths rent from oak are sometimes used. Lath and a half should be used for ceiling and soffits, and is generally used also for partitions, except in rather inferior work.

Substitute for Laths. Sheets of metal variously prepared are now frequently used in place of wood laths, and have the advantage of being non-combustible. The most usual kinds are *expanded metal* lathing, which forms a kind of inset and gives a good key to the plaster: it can be obtained in large sheets and can be adapted to irregular surfaces.

Thilmil consists of thin steel sheets from 5 ft. to 6 ft. long and from 12 in. to 24 in. wide, perforated with sections alternately raised and depressed to afford a key; this may be fixed to small iron standards in forming fireproof work.

Dovetailed metal lathing has already been described [page 4756], and is an excellent substitute for wood laths.

Plasterer's Terms. Plastering is applied both to solid surfaces, such as brick, stone, or concrete, and also to surfaces formed by laths laid side by side. In almost all cases there are at least two coats laid on and very often three. On solid walls one-coat work is usually described as *rendering*; two-coat work as *render and set* or *lay and set*; three-coat work as *render, float and set* or *lay, float and set.* On partitions the work is described, if one coat only, as *lath and plaster* or *lath and lay*; if two coats, as *lath, plaster and set* or *lath, lay and set*; three-coat work, as *lath, plaster, float and set* or *lath, lay, float and set.*

The term *plaster*, if used alone, is generally taken to indicate work executed in plaster of Paris. The material in general use, composed of lime, sand, hair, and water, is generally termed *lime plaster*; but there is a good deal of uncertainty and laxity in the use of plasterers' terms, which vary in different districts.

Coarse stuff, or *lime and hair*, or hair mortar, consists of 1½ parts of sand to 1 of lime putty mixed with water, and to this is added beaten hair in the proportion of 1 lb. of hair to 3 cubic ft. of stuff, and this is thoroughly incorporated with the larry. When well mixed in sufficient quantities the hairs should be found about 1/16 in. apart; and if a little is picked up with the end of the trowel, it should cling to it and not drop off. The consistency is important, as, while it must be plastic enough to work, if too soft it will drop off, especially in the case of ceilings.

Fine stuff or *setting stuff* consists of fine lime putty and fine, sharp, washed sand. The proportions vary somewhat, but the general proportion is 3 of sand to 1 of putty. It may be allowed to stand after thoroughly mixing till nearly hard but not dry, and is then knocked up again to the required consistency with water or lime water and at once used. It is less likely to shrink and crack if used in this manner. It may be mixed with colouring matter to any desired tint, or with materials that will give it a brilliant or marble-like surface; this is done by omitting one part of the sand and substituting for it one part of crushed marble, alabaster, or spar. Some white hair was often mixed in the setting stuff where only hydraulic lime was available, which cannot be easily manipulated, but is not so often employed now.

Gauged stuff is a term applied to either coarse or fine stuff which has a certain proportion of plaster of Paris mixed with it. This is done with the object of shortening the time within which the material will set. For coarse stuff and setting stuff one part of plaster to four parts of stuff may be used, or a larger proportion of plaster up to an amount equal to the coarse stuff, depending upon the rapidity of setting required and the strength of the plaster. For heavy cornices the proportion should not be lower than 1 to 3, which is also the proportion used with putty.

Stucco. *Stucco* is a term somewhat loosely applied to various plastic mixtures in England, and has been to some extent superseded by Portland cement for external work, and by Parian and other similar cement for internal work. It differs from ordinary three-coat work mainly in the manner of mixing and working the final coat, the first two coats being similar to three-coat work.

Common stucco is composed of 3 parts coarse, sharp sand and 1 part of hydraulic or grey lime and a little hair, and is used for external work, and the surface is finished with a hand float.

Rough stucco is used largely for interiors and in imitation of stone. It is formed with three parts of coarse sand and two parts of greystone lime. It is laid with a trowel, and after being ruled in with a straightedge, is scoured with a hand float, and afterwards with a felt float, which is an ordinary float the surface of which is unplaned and covered by a felt pad. The surface of the stucco is patted with this, and may be made to resemble the texture of stone, and, if required to represent ashlar, joint lines may be indented in the required positions with a jointer. This work may be tinted to represent the colour of stone by mixing with it ochre or other colour with dilute sulphuric acid.

Trowelled stucco is used for work that is to be painted; the coat is formed with 2½ parts to 3 parts of sharp washed sand, not too fine, and 2 parts of chalk-lime putty, and is laid and traversed in all directions with a floating rule, then scoured without water, and after an interval scoured again with water and immediately after with the trowel, which is continued till the work is so hard that no impression is made, and finally brushed over with a soft damp brush. The surface when dry is excellent for paint.

Plaster Work. The method of carrying out ordinary three-coat work is as follows: the first coat is formed of coarse stuff, and applying it to walls, partitions, or ceilings is described as *pricking-up*. The material is placed on the hawk, and thence transferred with a trowel to its position; in the case of ceilings, it is first worked on in a diagonal direction as the laths are stiffer when this is done, and each trowelful is partly covered by the succeeding one. It must be laid with sufficient pressure to force it between the laths to create the necessary key. The coat is laid as evenly as possible, from ⅜ to ⅝ in. thick.

The first coat on walls is termed *rendering*, and is similar in substance; the walls are well swept over with a coarse broom, and thoroughly wetted, to prevent the brickwork from absorbing the moisture from the rendering. The joints should be raked out for a depth of about ¾ in. before the mortar is set, to give a good key.

The first coat, after laying on both walls and partitions, must be *scratched* or *keyed*. The work is allowed to stand for an hour or two till it is firm; the scratch is then applied uniformly over the surface diagonally and crossed: scratching may be best done with a single lath, but takes much longer than with the scratch; the object of scratching is to provide an efficient key for the next coat.

Floating. Applying the second coat is termed *floating*. This may be done at any time after the first coat is dry, but if it has been left some time, it should be swept over to get rid of dust, and a damp brush should be passed over it. The material used in this coat is also coarse stuff, but it requires to be more plastic, and may have rather less hair than first-coat stuff. This coat brings the surface of the wall to a fairly true face, and must be carefully prepared for. The first process is to form screeds, which are thin strips of plaster, to serve as guides to the floating rule or running mould. In plumbing, an ordinary plumb rule may be used, or a line and plummet. The first process is to form *dots* top and bottom, unless the skirting grounds are available for use in place of bottom dots. The upper dots are formed just below the cornice level; they may be formed by nails driven through the first coat, and the head left projecting about ½ in., and they are adjusted with the plummet till perfectly in line, and their projection gives the proper thickness for the floating coat. The dots are finished by laying narrow strips of gauged stuff in a vertical line with the nails; these are worked down with the floating rule till they correspond in thickness with the projection of the nail. These dots may also be formed with pieces of lath about 6 in. long on a piece of coarse stuff, the thickness being adjusted with the plummet. When the top and bottom dots are completed, and are truly in a plane not only vertically but horizontally, vertical screeds are laid between each pair of dots and worked perfectly true with the rule. These vertical screeds should not be more than 6 ft. to 9 ft. apart, and when completed the nails used for dots are extracted.

Flanking. When the screeds are hard, if the surface of the first coat is seriously hollow in places it should have additional material laid on and scored: then each bay is laid with coarse stuff, which is worked upwards from the bottom, and the surface is then ruled even between the screeds with a floating rule, which carries off any superfluous material. Any hollow places must be filled up. This process is termed *flanking*, and is continued till the whole wall surface is covered and forms a perfectly true plane surface. Even if, as in common work, the screeds generally are not truly plummed, any salient angles must be so dealt with. Dots are similarly prepared for ceilings, and are made perfectly level with the help of the levelling rule, and screeds are then formed and the flanking completed. At angles the float cannot work close, and a seam is left; this is trimmed off square with the laying trowel after all floating is complete.

Scouring. *Scouring* the floated coarse stuff hardens the surface and prevents cracks in it and in the setting coat. The floated material is allowed to stand till the moisture has evaporated from the surface and it is firm. Scouring is carried out by a hand float, which is pressed hard upon the material and passed rapidly over it with a circular motion. The float is held in one hand, a stock brush in the other, and with it the surface is sprinkled; any small hollows left by the float may be filled in, and the whole surface should be treated in a uniform manner. A second scouring, and in very good work a third, may take place after an interval of from three hours to five hours, and the last scouring is continued till there is no moisture on the surface. Scouring is not required for Portland cement or when this coarse stuff is mixed with hydraulic lime.

Keying. The effect of scouring is to leave the floated surface smooth and close, and if the thin setting coat is laid on this, adhesion between the two is apt to be imperfect; after scouring, therefore, the surface must be made rough to secure the necessary key. This is done by brushing the surface as soon as scoured with a stiff whalebone broom, or by the use of a *nail float* which is an ordinary float having the point of a nail projecting from it about ⅛ in., or with a *devil*, which is similar, but has four such points, one near each angle. This tool should be worked with a close circular motion, and scores the surface, thus providing a key for the setting coat. Cornices are run before the final or setting coat is laid, but the work on this coat will be considered as following on, and cornices dealt with later.

Setting Coat. The material used for the setting coat is *fine stuff* or *setting stuff*, and has been already described. It should not be applied till the floating is well set and nearly dry; but if it has become quite dry it should be well wetted a day or two before the setting coat is applied. The setting is laid in two coats, one directly after the other, and both coats are laid with a skimming float. As soon as one wall, or bay, is completed, it is scoured, trowelled, and brushed.

Scouring is carried out with a hand float, and water is applied with a stock brush. After a short interval the operation is repeated, and it is finally scoured with a cross-grain hand float, with a sparing use of water, and is continued till an even close-grained surface is secured. This work is followed up by trowelling, for which the work is again sprinkled and the trowel well worked over the surface, which is afterwards brushed over with a wet stock brush, and finally with a half dry one. The thickness of the setting coat is usually about ⅛ in., and if the wall is required for painting, screeds may be used for the setting coat.

In the case of second-class work, the setting coat is laid as a single coat, scoured and trowelled once and brushed over, and in inferior work the coat is very thin, formed of quick-setting stuff, and is then trowelled and brushed.

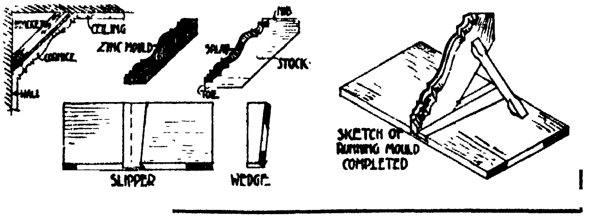
Internal angles must be carefully squared and made true with a cross-grained float. External angles may be treated in various ways, beaded or moulded or finished with an arris. Sometimes a wood bead or wood bullnose is used to form the angle. The circular bead is fixed to the walls, and the floating coat is cut away on each side to form the guide when the setting coat is laid. Unless the angles are in wood, they are usually in Parian or Keen's cement, and this material is returned on each face for about 2 in. The floating is cut away to a square line down to the brick, which is dusted and wetted, and the bead or arris is then run, running rules having been fixed on each side; the edge of the return forms a finish for the setting coat.

Working Keen's, Parian, and Martin's Cement. These cements are largely used for plasterer's work in place of ordinary lime plaster. Much economy of time may be effected by their use, and they may also be painted, papered, or distempered as soon as finished. They work easily, and give a very smooth, hard surface, and when not used generally for plastering, are very usually employed for salient angles and similar purposes. They will not, however, resist the effect of moisture, and are not therefore suited for external work; if used in internal walls that are in any way damp, such walls must first be rendered in Portland cement. Care must be taken to see that they are used without addition of plaster, which may cause them to swell The cost of these cements is higher than that of plaster. In the case of lathwork, the nails used must be galvanised, or otherwise protected from rusting, and all nails used in forming dots must be extracted. For first coat and floating on ceilings the proportion used are 1 of cement, 2 of clean, sharp sand, and hair in about the proportion used for lime plaster; for walls a little more sand may be used—about 2 of cement to 5 of sand. A coarser form of cement is used for the earlier coats than for the final coat. Where it is not desired to proceed rapidly with decorating, the walls may be rendered and floated with Portland cement and sand, used in the proportion of 1 to 3; this is more economical, but generally results in a white efflorescence appearing on the surface, and must be given time to dry out before the surface can be painted or otherwise treated.

The materials must be carefully mixed dry and then the water added and finally the hair, which should be first beaten and soaked. The material is used fairly stiff, and it is important that any work begun should be finished on the same day. The first coat when finished is scratched, and should stand for about 20 hours before floating. The screeds for the floating coat are generally narrow, and the sides are cut square, and the material, when these are set, is ruled in with a floating rule till the surface is perfectly even and true, and when firm it is brushed over with a coarse broom to provide a key.

· For the finishing coat a fine cement is used and generally worked neat. It is first gauged smooth and stiff and may have additional water added afterwards to reduce its consistency if necessary: this coat should not exceed ⅛ in. in thickness and must be carefully ruled till perfectly true. It is laid generally in two coats, the first fairly stiff, and after this has been ruled, additional cement gauged less stiffly is laid and ruled. In about an hour or so it becomes firm, and may then be scoured without much water, the operation being twice repeated to secure a firm, close, even surface. Trowelling follows on soon after scouring, very little water being used, and this operation is also twice repeated.

Preparing for Cornices. Cornices must be provided with some kind of core to which the plaster can be applied. In the case of external cornices this may be of rough stone or brick built into or corbelled out from the wall, which should conform closely in its outline to the finished lines of the cornice. For internal cornices the preparation will depend on the size of the cornice and its form. When the projection is small, a series of spikes may be driven into the wall, the heads being left projecting to the extent required to form the mouldings and tarred bands twisted between them; but where the section of the cornice has a considerable projection, brackets are used cut from boards and fixed at intervals in the angle between ceiling and wall. These are afterwards lathed with ordinary laths or with metal lathing. These brackets should be cut to such a shape as to secure that the thickness of the plaster should be approximately equal throughout. This cannot be secured at every point, but should be aimed at; if thinner, the plaster may crack; if thicker, it is wasteful, and unduly loads the brackets. Any small mouldings projecting considerably from the general line may be strengthened by the use of projecting nails. The actual section of the bracket must be varied for a plain and enriched cornice, even if of the same profile, as the enrichments cannot be run, but must be cast and a bed formed for their insertion.



27. RUNNING MOULD

Cornices. Cornices are formed by means of a running mould [27] cut to the profile of the proposed mouldings. The actual mould for forming the profile is now usually of zinc, except in the case of Portland cement mouldings, when iron is often used. The thickness of the zinc may be about $\frac{1}{16}$ in. or a little less, and the zinc profile, or *plate*, is fixed on a wood backing, or *stock*, which in turn is fixed to a wood plate, or *slipper*, and supported by stays which form handles. The plate is marked with the desired profile, cut, and then filed perfectly true, and is usually about 4 in. or 5 in. in width, and has squared ends of about 1½ in. corresponding with wall and ceiling surfaces. All woodwork is carefully planed; the stock is cut to a profile corresponding with the plate but set back about $\frac{1}{16}$ in. except at the *nib*, or upper edge, which bears on the ceiling, and the *toe*, which bears against the wall and assists the plate to run freely. The edge of the stock is splayed back from the plate still further; the stock is made wider than the plate, which is screwed or nailed to it; the bottom of the stock is fitted into the slipper, which is carefully squared and grooved with a dovetailed groove, into which the stock is fixed by a wedge and secured with nails. The handle or stay is formed out of a square piece of wood the angles rounded off in the centre; the ends are splayed and fixed, one to the stock and one to the slipper, so as easily to clear the moulding when grasped by the plasterer's hand in working. When the mould is to have considerable use, the nib and each end of the slipper may be protected by a piece of zinc or leather. A splashboard is sometimes added, and is fixed between the back edge of the slipper and the stock.

In preparing a running mould for an enriched cornice the enriched members are omitted and a bed sunk for them which can be run with the other mouldings and into which the cast enrichment is afterwards inserted.

Running screeds are prepared on the walls as bearings for the mould, and the running rules are then fixed. These are long strips of wood 2½ in. to 3½ in. broad and ½ in. thick, planed all round, and fixed against the screeds, and form guides for the running moulds.

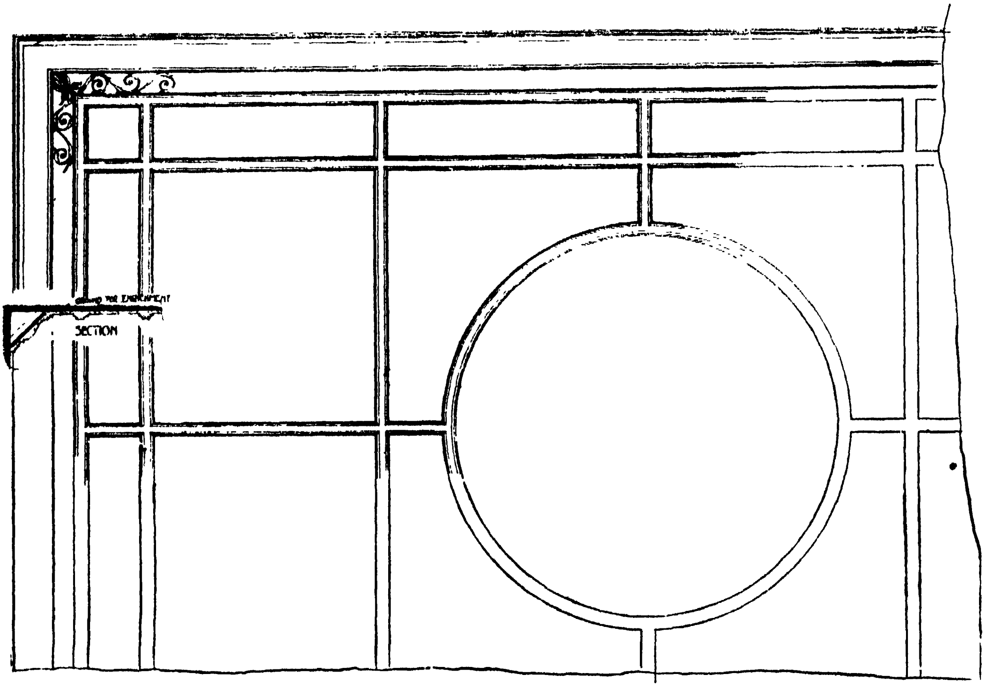
The mouldings are first roughed out, and then finished with a fine thin coat, and for this roughing the running mould which gives the finished profile must be *muffled*—that is, the edge of the mould must be covered to an extent equal to the thickness of the final coat. This may be done by gauging up plaster and covering the bevelled edge of the stock with it till the plaster projects about ¼ in. beyond the plate, and, when it has set, trimming it down to about $\frac{3}{16}$ in. projection, which will leave sufficient thickness for the finishing coat. Another method is to provide an extra *muffling plate*, cut to the requisite profile, and screwed over the plate. When the moulding has been roughed out, the muffling is removed, and the plate used for finishing.

Running Cornices. Where brackets and lathing are used, the laths are often coated with gauged coarse stuff and scratched before the screeds for floating the walls are prepared. This dries and stiffens the lathing before the mouldings are roughed out. With large mouldings, and when metal lathing is used, the whole cornice is roughed out with gauged coarse stuff. This must be laid on in regular thickness, the form of the mouldings being built up as nearly as possible with the trowel first, and the muffled mould is then run over the mouldings, carrying off any superfluous material; any hollow parts must be filled in, and the whole cornice brought to a true and uniform profile throughout its length.

Finishing Cornices. The gauged stuff for finishing must be prepared on a clean gauge board. The plaster and water are first mixed, and the putty afterwards added; the stuff is laid in the cornice with a gauging trowel, following the form of the mouldings; the mould is run along by one man, except in the case of very large mouldings, when two may be necessary. Any members of the cornice not properly filled out must be fed with additional stuff, and the operation goes on till the cornice is complete. Finally, a thin coat of fine putty, gauged with less plaster, is drawn over the mouldings, and the mould is quickly and steadily drawn along the whole cornice as a finish.

Mitring. Where two walls meet at either an internal or external angle the cornice on these walls meets in a mitre line. This section cannot be run with an ordinary mould, and though mitre moulds are sometimes employed, these angles are, as a rule, made by hand, and are mainly worked with the joint rule, the smaller members and those at the top and bottom being first worked, and the larger members ruled in afterwards. *Small tools* are used for laying in the stuff, cleaning out the intersections, and stopping any small holes.

Fixing Enrichments. In the case of a cornice which is enriched—that is, in which the mouldings are cut on the face, and are not therefore uniform in section, the enriched members cannot be run, but a sunk bed is formed for them, and the enrichments are cast in blocks and set in the finished cornice. The beds are scratched when formed, and, for fixing, the bed is dusted and wetted. The fixing stuff, which is fine gauged stuff, is spread thinly over the bed to fill up the scratches, and over the back and sides of the cast; and the heading joints are covered with a little fine plaster gauged with size water. The cast is then inserted in position, slid backwards and forwards to drive out any air, and then the next length is similarly treated. Great care is required in setting out any enriched members so that they shall repeat an exact number of times in a given length, and any necessary adjustment must be made so as to secure a proper mitre. This is arranged for as far as possible in the shop.



28. PART OF PANELLED PLASTER CEILING

Such casts are usually made in moulds of gelatine; specially prepared wax and plaster are also employed for making moulds for casting plaster ornaments and enrichments, but the details of their preparation cannot be entered upon in this article, which deals with the work more directly connected with actual building operations. Moulded work is not confined to cornices, but may be used in many other situations, especially in ceilings [28] and in forming panels and other enrichments for walls. In the case of elaborate moulded ceilings, especially where the mouldings are small and not run in straight but in curved lines, these may be cast in moulds and applied as described for cornice enrichments.

Rough Cast. *Rough cast* is a method of finishing external walls, and may be used for plain surfaces or in conjunction with timber framing; it is also known as *pebble dash.* It is a very durable form of plastering, and produces a surface of a rough texture, much superior in effect to a smooth plaster face. When executed in lathing, the laths used should be double laths. The first coat is formed with coarse stuff having a liberal amount of hair, which is scratched; or the first coat may be formed of Portland cement in exposed positions. The second coat is also of coarse stuff, well worked to an even consistency, and not applied till the first coat is thoroughly dry: this coat is laid fair, and while still soft the final coat is applied.

The final coat is usually formed of shingle or fine gravel, well washed and passed through a sieve from ¼ in. to ½ in. mesh, and put into a tub containing hot hydraulic lime, mixed with water into a fluid state and well stirred. The shingle is taken out as required, and thrown or dashed evenly on to the soft second coat with a scoop, or hollow trowel, and forms a rough but regular surface. Ochre or other colour may be mixed with the lime to give a tint to the rough cast surface.

Repairing Plaster Work. Where cracks in ceilings are only slight they are often merely stopped before the ceiling is rewhitened, but large cracks and loose plaster must be carefully cut out; care must be taken not to disturb adjacent work, and in forming patches sharp angles are to be avoided. The edges of the old work must be cut neat and square, and in some cases the lathing may have to be made good before replastering. The edges of the old work must be wetted, and the laths just damped after dusting. The repair is generally executed in gauged coarse stuff and gauged fine stuff, or in best work with Parian or Keene's cement.

PLASTERING *concluded; followed by* INTERNAL PLUMBING

MAKING MILLINERY BOWS

The Art of Making Effective Bows and Rosettes of all Kinds. The Butterfly and Alsatian Bow. Chiffon and Tulle Rosettes

By ANTOINETTE MEELBOOM

MILLINERY bows are made in a great number of shapes and sizes. They may be made of silk ribbon of an immense variety of kinds and widths, velvet ribbon, lace, piece velvet, chiffon, tulle, straw, kid, braid, beaver, cloth, etc., but each bow is made on the same general principle. Before using new ribbon, it is better for an inexperienced worker to practise on a piece of muslin, or even tissue paper, cut in strips the width and length of the ribbon; for when once the ribbon is creased, it cannot very well be altered without taking away the freshness of its appearance. By practising in this way, the beginner will obtain that lightness of touch, quickness, and "finger-knack" which is so necessary in all millinery trimmings, and especially in bow-making. She will, in a short time, produce bows which would be a credit to an experienced milliner.

Bows are always made by hand before they are sewn on, except in the case of large hats with a bow or rosette at each side and a piece of ribbon going across the centre.

When making the bow, the hat for which the ribbon is needed should be in front of the worker, to get the size and effect. Bows are best made from one length of ribbon which is not more cut than necessary, unless a bow with many ends is required.

A bow, although it should appear to be untouched by hand, must yet be firm. When buying ribbons for bows take care that the assistant does not crease up the ribbon to show how it will look, as the crease may happen to come across the widest part of the loop. The following characteristics of a well-made bow should be noted:

Pleats should be even, fine, and straight;

Each loop and end brought back to its root or starting point, and the bow made in one piece, if possible;

The ribbon kept fresh-looking, free from twists and any re-arrangements;

The size of loops made in accordance with the width of the ribbon;

The wire (if used) firmly fixed, and the ribbon sewn lightly to it, free from strain.

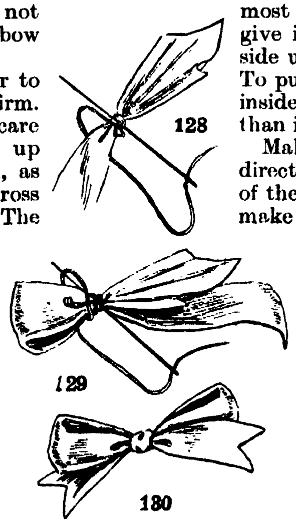
We shall first make a few bows which never go out of fashion. To keep up-to-date in the latest shapes of bows it is necessary to study the fashions prevalent at the time. Those who have an opportunity of visiting trade houses will have a great advantage. Otherwise, careful observation of the best milliners' windows, of well-dressed people in the parks and promenades, of ladies' magazine advertisements, will help the milliner to see what is most in vogue. Even if she has no originality, she will at least be able to copy, after practising the instructions we shall give.

The quantity of material required for a simple bow is ¾ yd. of 5-in. wide ribbon. Start at one end—not in the middle. Hold the ribbon in the right hand, and with the left pleat it firmly and evenly.

Bind it *tightly* round the pleats with mounting wire, inserting one end of the wire in the pleat; or with cotton, using a strong needle and No. 10 cotton. Insert the needle once through the pleats and turn the cotton round tightly three times; put the needle through again [128].

Gauge the length of the loop by the width of the ribbon—the wider the ribbon the longer the loops. Pleat the ribbon *evenly*, and bring the pleated part back to the centre, and bind it tightly with mounting wire or cotton, having the loop *opposite* the end just made [129]. This centre is called the *root* or *waist* of the bow.

If there is a right and wrong side to the ribbon, as there is in velvet ribbon with satin back and most ribbons with patterns on them, give it a sharp twist to keep the right side up, before making the second loop. To pull up the loop, place the forefinger inside. Never crease or touch bows more than is just necessary to secure them.

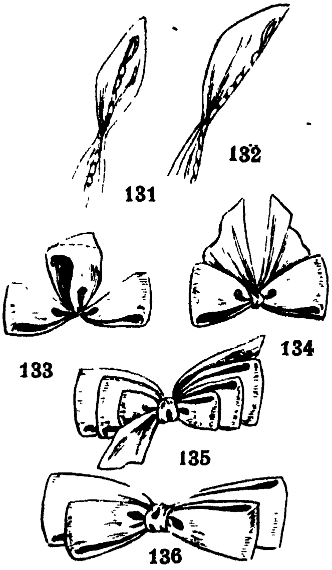


128–130. A SIMPLE BOW

Make another loop in the opposite direction, which will place it on the top of the first end, and for this simple bow make it the same length as the first loop, bringing it back to the root or starting point. Cut off the ends slantways, or fray them out. The triangular piece cut from the first end will make the tie-over. Turn in cut edges, twist it over the root, and neatly finish off at the back with a few stitches [130].

On this principle all other bows are made. They may be varied by having several loops of different lengths, but they are always placed alternately right and left to the root.

Good ribbons require no stiffening, provided the loops are not too long. Large bows of wide ribbon, and all soft ribbons, require wiring. Use support wire or ribbon wire, shredded. Of the last, use each strand of the wire separately, which can easily be done by tearing it along the soft part. Wire-stitch it along the centre, and zig-zag it for wider soft ribbons. Use very fine sewing silk to match the ribbon, and let the stitch taken through be hardly visible [**131 and 132**]. In the same way, coloured support wire to match the ribbon can be used. It is a little more difficult to manipulate, but a lighter effect is obtained.



THREE STYLES OF BOWS
131 and 132. Wiring the bow
133 and 134. Butterfly bow
135. A tied bow **136.** Alsatian bow

Ribbon wire can also be used. Place the end of the ribbon wire inside the centre pleat, bring the needle through, bind it round with cotton, and take the needle through again. Gauge the length for the loop, and allow the same length for the ribbon wire; bind it over with the ribbon, and stitch it and bind round the root of the bow. Be careful not to strain the ribbon tightly on the wire.

Secure the wire at the back with silk to match the ribbon, just below the top of the loop.

Upstanding or broad ends should be wired half way up, never quite to the top. In some cases the ends are wired along one or both sides of the ribbon.

A butterfly bow [**133 and 134**] can be made in rather narrow width ribbon, in which case it will be used for bonnet trimming. It has two loops and two upstanding ends, shaped at the end as butterfly wings. It also makes a handsome trimming for front of hat if made of a ribbon 9 in. to 10 in. wide, or a piece of silk.

Start this time with a loop, pleating each side separately. Make another loop in the opposite direction; then another standing up in the centre, turning in the end inside, passing the cotton used to secure the bow at the root through and through the loop. Place the tie through the centre loop. Cut this slantways [**134**], and shape the ends like butterfly wings. Quantity of ribbon required is ⅝ yd. of 2-in. wide ribbon velvet.

A tied bow [**135**] has as many loops of various sizes as desired, but only two ends, and is made, including the tie-over, in one piece. It is useful for children's washing hats and bonnets, and for various other millinery items. Keep the first and second loop the longest, graduating the length of each pair of loops. Begin with an end, next a loop 12 in. long, in opposite direction; another loop the same length, opposite the first, 12 in. long; then two loops 9 in. long, and two loops 6 in. long. Take the remainder of the ribbon, twist it round the root, and pull the end through the twist at the back, and the bow is finished. This bow can be made without the use of any cotton or mounting wire; the loops are kept firmly in place with the fingers till the tie-over—that is, the second end—secures them. Quantity of ribbon required is 1¾ yd. 5 in. wide.

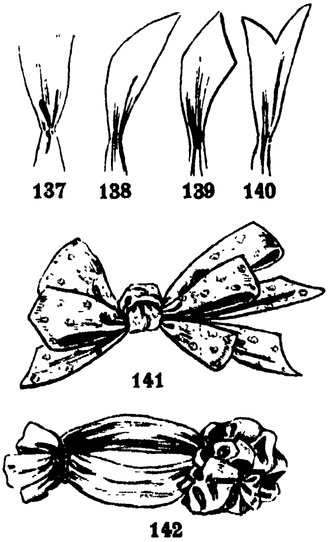
The Alsatian bow [**136**] takes 1¼ yd. of 3-in. wide ribbon. It is made of four loops, has no ends, and a large broad tie-over. Loops Nos. 1 and 2 are 12 in. long; loops 3 and 4, 10 in. long. These are used frequently for nurses' bonnets, etc., the loops reaching from ear to ear from the centre of the bonnet, only once pleated in the centre.

Fancy bows [**141 and 142**], with more than two ends, and more than two or four loops, are made on the same principle as described, several of the loops being cut after the bow is made. If upstanding ends are required, the tie-over is taken round them, and for a flatter trimming the tie-over is taken in the centre in the usual way. Two and a half yards is the very least quantity which can be used to trim a hat satisfactorily; if it is to be its sole trimming, 3½ yd. is an average quantity. For ruches, loops, and rosettes, more is required.

Ends of bows may be frayed [**137**], cut in wing [**138**], mitred [**139**], or cut to fishtail shapes [**140**]. The ends are sometimes vandyked, or treated in some other fashionable way.

Kilting the ribbon [**143**] makes pretty, effective bows or rosettes. Plain ribbons look better kilted than brocade, chené, or fancy ribbons. Mixing ribbons of different tones of the same colour makes smart bows. In the good French ribbons at least three shades of the same colour can be obtained, toning gradually from light to darker.

Piece velvet bows [**145**] are made of velvet cut on the cross and the edges roll-hemmed. The loops are pleated as in ribbon bows; but as velvet is so much thicker, it should be twisted as little as possible, and if a large bow is required, it must be made in two parts. About ¾ yd. on the cross is required, and the tie-over should be neatly made.



A FANCY BOW AND ENDS
137-140. Bow ends
141 and 142. Fancy bows

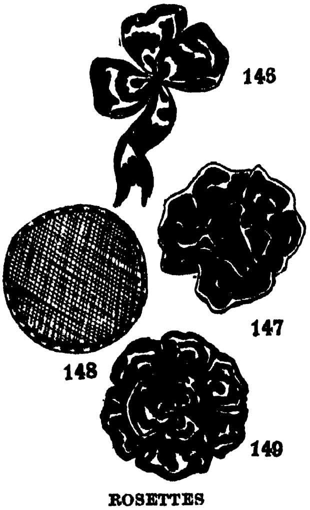
Bows of straw, braid, etc., are made in the same way. Lace insertion sewn between the rows of straw, or gauged tulle, chiffon, or silk all make pretty variations of bows. Two or even three colours of straw worked in one bow or rosette are also very effective [**144**].

In stitching bows to the hat, stitch firmly, stabbing the needle in the hat through the back part of the tie-over. Tie inside. Catch each loop to the brim with an invisible tie-stitch in a becoming position.

Rosettes. Rosettes are made in ribbon, lace, tulle, silk, velvet, or straw. Like bows they are continually changing in style, and even a greater variety and greater originality is displayed in the last new ones. The following are a few of the standard styles, which always remain in vogue.

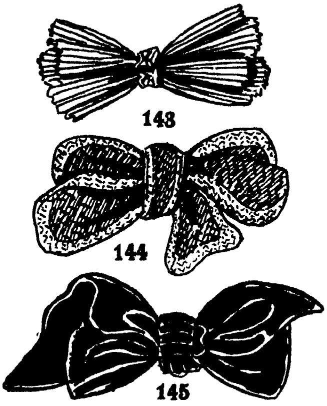
The loop rosette [**146**] consists of a succession of loops each made independently, but all coming back to the centre or starting point; 1¾ yd. of 7 in. wide ribbon is needed. Start with a loop 7 in. long. Pleat the ribbon and twist round the cotton at one end as in diagram **128**; take the ribbon over the forefinger and pleat at 7 in. Then bring it back to its starting point and twist round the cotton, which will form the centre or root. Make five, seven, or nine loops, each being brought back to the centre and the cotton twisted round. The number of loops depends on the width of ribbon and size of rosette desired.

Arrange the loops in circular order, finishing the last one in the centre, unless an ornament, floral, or other fancy centre is going to be made [**149**]. Be careful the loops are close together, for if each loop is not stitched to the starting point a gap will be left between, taking away the rounded, full look. The name "chou" is sometimes given to this rosette when made very full and with rounded top. Most of the other kinds of rosettes require a foundation to which to sew the loops. For this cut a circle, about 3 in. in diameter, of buckram or double French net [**148**]; wire round with support wire, overlapping the ends for 2 in., and bind with sarcenet ribbon. Another way of making a rosette is with very small loops only 3 in. in entire length, sewn on a foundation, round and round. It takes 4½ yd. of ribbon for each rosette, and has a flat appearance.



ROSETTES
146 and **149.** Loop rosette
147. Crossway rosette
148. Foundation for rosette

For crossway silk or velvet rosettes [**147**] cut the velvet or silk twice the width required, and let the length be according to the width and size of rosette. The narrower the velvet the smaller the rosette, and vice versâ. One crossway length of velvet of about ¾ yd. long and 3½ in. wide makes a small rosette suitable for a bonnet, or to fill up a small space on a bandeau at the back of the hat. This size can be made without a foundation, and two lengths are better than one. To make this, shade and join the velvet; run the raw edges together with strong cotton and pull it up tightly. Sew it to a foundation; do not skimp the outside edge, and finish it off neatly in the centre.



FANCY BOWS
143. Kilted bow **144.** Straw bow
145. A piece velvet bow

Gathered ribbon rosettes are made in exactly the same way, except that the ribbon is, of course, on the straight. Gather it either along one edge or through the centre. Pull the cotton up tightly.

For silk rosettes, if not used double, roll hem-stitch, tuck, or bind one edge to form the trimming.

For crush rosettes of velvet or silk cut a circle of velvet or silk from 9 in. to 20 in. in diameter [**154**]. If the velvet or silk be soft, use a light leno or book-muslin for interlining. Gather it all round, draw up to the circumference of foundation. The centre will fall in light folds and puffs, which secure here and there to the foundation with the tie-stitch. The better the quality of the velvet, the lighter the rosette will look, and the fewer the stitches needed to keep the puffs in place [**150**].

Odd bits and cuttings of velvet or silk of any shape or size can be used for this rosette, gathered up round the edge and sewn in.

For baby ribbon rosettes [**151**] mark on a piece of net a circle the size of a shilling. Make each loop by folding the ribbon over the finger, and stitch it to a foundation on the outside of the circle marked, then another circle just inside, and so on until the foundation is covered. Finish in the centre with three upstanding loops. Quantity required is 6 yd.

There is another method of making these rosettes—without a foundation. Wind the ribbon entirely round a card 1½ in. wide and about 7 in. in length. Let each loop just overlap the last, and do not wind tightly. With a needle and strong cotton run through the top of the loops, carefully picking up each one. Slip the ribbon from the card, removing the loops in succession, draw up tightly and fasten off securely.

Chiffon rosettes [**156**] need 1½ yd. of double-width chiffon, cut through the centre selvedge way. This will make two or three smaller size rosettes.

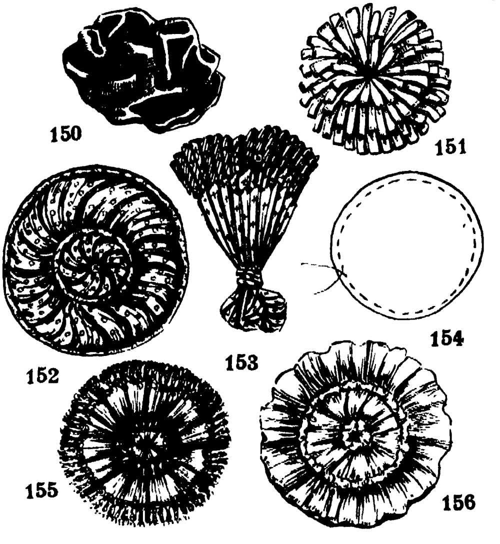
Make a fold the width required; pin this down, and make another narrower fold, and pin again. Run two or three gathering threads through all the folds at the bottom, draw up tightly and stitch together; finish off the centre with an ornament. Pull out each fold to produce a full, rounded appearance.

Chiffon, net, or tulle rosettes are made with the material cut on the straight; run the two raw edges together, draw up, and wind round from centre outwards.

For lisse, net, or tulle, the cut edges are sometimes turned to the centre, box-pleated there, and drawn up. The wider the rosette the greater the amount of fulness required, as it will want more material to set without skimpiness round the outside edge. Avoid showing raw edges, and finish off the ends neatly.

Tulle rosettes take 2 yd. of double-width tulle and 6 yd. of lace insertion, ½ in. wide [**155**].

Cut the tulle in strips 9 in. wide, fold them in half, and sew the lace on to the fold so that it stands out well. Gather the two cut edges. The lace can be sewn on about ½ in. from the "centre edge." Tulle rosettes sometimes have their folded edges cut after they are drawn up; it gives a pretty, fluffy appearance, though they do not wear so well.



SOME EFFECTIVE ROSETTES

150 and **154**. Velvet rosette **151**. Baby ribbon rosette
152. Drawn silk rosette **153**. Cockade rosette
155. Tulle rosette **156**. Rosette of chiffon

A cockade rosette [**153**] for bonnets or toques, requires 1½ yd. of 8-in. wide ribbon; if two shades are used, ¾ yd. of each is enough.

Kilt the ribbon and make three ends; wire at one edge, unless a firm silk ribbon is used, and make two small loops and a tie-over.

For a drawn silk rosette [**152**] cut ⅜ yd. of crossway silk in two lengths; join them in a circle. Run ½ in. tuck along the edge and another through the centre. Insert a cotton cord in each, and gather cut edges tightly to form the centre, which is finished with an ornament. Secure outer edge to foundation, also the second cord.

Kid, braid, or straw rosettes are made in the same way, but each of these requires a foundation.

Rosettes should be sewn to the hat, if possible, through the centre, or *between* the loops or flutes.

Hat Trimming. To sew on feathers, nip off any superfluous length of wire and bend up the remainder, which should be bound with a small piece of crossway velvet to prevent the cotton slipping off the stem or wire when sewing the feathers on.

When a quill end or fancy sheath is used, do not bind the end of the feather, but slip the stem in the sheaf, and sew through the quill end or the holes in it. Tie the cotton about 2 in. from the end of the feather on the underside; leave the cotton loose for about 1½ in., and tie in position to edge of brim, or wherever it is required to fall. A feather should never be fastened tight down to the brim. When it has to be stitched to a velvet hat, first sew it to a piece of stiff net, which can be secured to the hat more firmly and with fewer stitches. A buckle, ornament, or some other kind of trimming must neaten the end in this case.

Feathers on lace or net hats are sewn to one or more wires; a piece of stiff net is placed at the back and the stitching taken through. Some feathers require to be wired down the stem, to make them retain their position. In this case use support wire, and nip round the end, making a small loop. The wire should leave off about 2 in. from the end.

Wings and quills are stitched securely at the base. Quills may even have a stitch taken through the stem, which can be done by using a No. 3 "between" needle. If wings are padded, secure them through that part. Sew the ends in position with the tie-stitch.

Jet and fancy ornaments, such as buckles, clasps, etc., must be always stitched in the centre as well as on each side, to prevent their slipping sideways.

Birds, if worn, must be firmly sewn to a wire, which is generally fixed at the back. There is so much choice in the manufactured wings and quills made from poultry feathers, neatly mounted and dyed to any colour and shape, that there is no need to use the aigrette of living birds. Such ornaments will never be worn by the woman who takes the trouble to learn at what cost these things are collected and prepared.

To stitch on flowers or wreaths, cut off any unnecessary length of stem and bend up the remainder. Stitch the flowers firmly to the hat by taking the stitches over and over from side to side of the stem and cutting off those that are not needed. Arrange the flowers and foliage in position, and tie-stitch them to hat.

A trail of flowers is caught here and there with the tie-stitch very loosely to the shape. Coloured cotton to match must be used. No stitches should show, and the trimmings should look as if they are "laid" on the hat.

TEXTILE CALCULATIONS & DESIGN

Basis of Counts. Drafting the Design. Structure of Cloth. Double Cloths. Contraction of Warp. Textile Books

Continued from page 5382

By F. S. HUDSON

THIS article is the concluding one in our textile series. We then proceed to study the theory and practice of dyeing. A fitting conclusion to our textile study will be a consideration of textile calculations and a concise summary of the principles of textile design, with a list of the best textile books, which may be recommended to those who wish to pursue the subjects of textile theory and practice into detail.

Calculations. The worsted count of yarn is based on the number of hanks or lengths of 560 yd. each which weigh 1 lb. avoirdupois. This is signified by writing the number opposite the colour of the yarn—as "$^1/12$ black worsted," which means there are 12 hanks or lengths of 560 yd. each which weigh 1 lb., so there will be 560 × 12 = 6,720 yd. of yarn in 1 lb. of this material. In a yarn which was numbered $^2/24$ worsted, it would have just the same number of yards per lb. as the above yarn, because it would be composed of two threads of $^1/24$ yarn, which is equal to one thread of $^1/12$ yarn. It is written $^2/24$ to show that it contains two threads of $^1/24$ instead of being composed of one thread only. To arrive at the true count, it must be divided by the number of threads which make up the yarn—that is, 24 ÷ 2 = $^1/12$ worsted.

Cotton yarn is calculated on the number of hanks or lengths of 840 yd. each which weigh 1 lb., with the same rules as apply to worsted. Yorkshire skein woollen yarn is based on the number of hanks or lengths of 256 yd. which weigh 1 lb. If 10 hanks or lengths of 256 yd. each, woollen, weigh 1 lb., it is 10-skein yarn; also, if 10 yd. of woollen yarn weigh 1 dr., it is 10-skein yarn, because 1 lb. avoirdupois contains 256 dr., and one hank of Yorkshire skein woollen yarn contains 256 yd. Spun silk yarn calculations are based on the number of hanks or lengths of 840 yd. each which weigh 1 lb., but with this important distinction, that however many threads go to compose a spun silk yarn, the count is signified by the first number. $40/^2$, $40/^3$, $40/^4$ spun silk are all the same thickness, although the first is composed of two threads, the second of three threads, and the third of four threads respectively.

Testing the Counts. For testing the counts of worsted yarn there is a small weight which weighs 12½ gr.: this is used on delicate scales to obtain greater accuracy, and this number is obtained by dividing the number of grains in 1 lb. avoirdupois, which is 7,000, by 560, the number of yards in one hank of worsted; this is put in one of the scales and the yarn in the other. This implies that if 1 yd. of worsted is found to weigh 12½ gr., it is 1-count worsted; similarly, if 12½ yd. of worsted is found to weigh 12½ gr., it is 12½-count worsted; also, if 20 yd. of worsted is found to weigh 20 gr., it is 20-count worsted.

For testing the counts of cotton yarn the weight is 8⅓ grains, obtained by dividing the number of yards in one hank, 840, into 7,000, the number of yards in 1 lb., and then tested in the same way as worsted. Yorkshire skein woollen yarn is tested by finding the number of yards which weigh 1 dr., obtained by dividing 256, the number of yards which is contained in one hank, into 256, the number of drachms in 1 lb.

Practical Calculations. The first useful calculation is that of converting a count of yarn in one denomination to an equivalent count in another denomination.

What counts in cotton is equal to $^2/24$ worsted?

$$^2/24 = {}^1/12\,\frac{560 \times 12}{840} = 8, \text{ or } {}^2/16 \text{ cotton.}$$

When this is worked out, it gives the above answer. This rule applies to all the above systems. A short method of converting worsted counts into cotton counts is to multiply by 2 and divide by 3.

What is the resultant counts of 40 worsted and 20 worsted twisted together?

$$40 \div 40 = 1 \text{ lb.}$$
$$40 \div 20 - 2 \text{ lb.}$$

40 hanks weigh 3 lb. of twisted yarn, and 40 ÷ 3 = 13⅓ counts.

If 60 lb. of twist is required composed of 40 and 20 yarn, how many lb. of each will be required to make this amount of yarn?

$$40 \div 40 = 1 \text{ lb.}$$
$$40 \div 20 = 2 \text{ lb.}$$
$$\overline{} = 3 \text{ lb.}$$

$$\frac{60 \times 1}{3} = 20 \text{ lb. of yarn of 40 counts.}$$

$$\frac{60 \times 2}{3} = 40 \text{ lb. of yarn of 20 counts.}$$

Total, 60 lb. of yarn.

To Find Weight of Warp. To enable us to do this, we shall require to know what length the warp is to be made, the ends per inch, the width in loom, and the counts of yarn.

How many lb. of yarn will it take to warp a piece warp 70 yd. long, 64 in. wide, 60 ends per inch, of $^2/24$ worsted warp and weft?

$$\frac{60 \times 64 \times 70}{560 \times 12} = 40 \text{ lb. of yarn.}$$

To find weight of weft, put picks per inch instead of ends, and take length of warp as above. This will allow for waste of weft during weaving.

The Diameter of Yarn. To find this, it is necessary to find the number of yards in 1 lb. of the yarn we want to find the diameter of, and then find the square root of this number: 10 per cent. of this number must be deducted for worsted, 8 per cent. for cotton, 16 per cent. for woollen yarns. This gives us the average diameter of the yarn.

What is the diameter of $^1/24$ worsted? This yarn will contain 560 × 24 yd. per lb., and the square root of this is 116, less 10 per cent. for worsted = 105, the number of ends of this yarn which can be laid side by side in 1 in. without compression, which implies that the diameter of this yarn is $\frac{1}{105}$ in.

The respective diameters of yarns will vary inversely as the square root of their respective counts.

The above calculation is useful in making cloths which have both counts of warp and weft alike, also the number of ends and picks.

To make a cloth in the above yarn with the 2—2 twill design, it would allow us to have

$$\frac{105 \times 4}{4 + 2} = 70 \text{ ends and picks per inch,}$$

because there are four ends and two intersections in this design. The diameter of the yarn is multiplied by the ends in design, and divided by the sum of ends and intersections.

COUNTS OF YARN

			of Yards per lb.
1	·666	2·187	23·750
2	1·333	4·375	33·500
3	2·0	6·562	41·0
4	2·666	8·750	47·356
5	3·333	10·937	52·950
6	4·0	13·122	58·0
7	4·666	15·309	62·623
8	5·333	17·500	67 0
9	6·0	19·683	71·0
10	6·666	21·875	74·8
11	7·333	24·062	78·5
12	8·0	26·244	82·0
13	8·666	28·437	85·333
14	9·333	30·618	88·695
15	10·0	32·812	91·333
16	10·666	35·0	94·333
17	11·333	37·184	97·593
18	12	39·375	100·39

Table for Reference. The useful table above gives the counts of worsted from 1 to 18, with the equivalent counts in cotton and woollen; also the square root of the yards per lb. of each count up to $\frac{1}{100}$ in. 10 per cent. must be deducted for worsted, 8 per cent. must be deducted for cotton, 16 per cent. must be deducted for woollen for the diameter of yarn. This is sufficiently accurate for all practical purposes.

Cloth Analysis. When a sample of cloth has been analysed and the design found, the amount of shrinkage in warp and weft must be estimated. This can be obtained by simple rule of three, so that if a sample contains 40 ends and picks finished, and has shrunk one-sixth, it will have $\frac{40 \times 6}{5} = 48$ ends and picks in loom.

After this, there are still two more important factors to find: these are the counts of yarn used and the weight of cloth. Broadcloth is usually made 56 in. wide and 37 in. per yd. allowed finished. To find the weight of a yard of broadcloth as above, multiply 37 by 56; this gives the number of square inches in this length. When this is divided by the number of grains in 1 oz., 437½, the answer is 4·73. This number represents square inches. Now, if a piece of cloth 1 in. broad and 4·73 in. long, or 2 in. broad and 2·36 in. long weighs 16 gr., a piece of cloth 37 in. by 56 in. will weigh 16 oz. So this is a ready means of obtaining the weight of a piece of cloth by weighing a small sample, without any calculations, by simply having a piece of card cut 2 in. by 2·36 in., and placing it on a sample of cloth and cutting cloth the same size and weighing on a grain balance.

The size of card to be used for any other length and width may be obtained by the above method. After the weight has been obtained as above, the counts of yarn can be got by taking a few threads from the cloth. If we can get 12 threads, each 3 in. long, and these are weighed on a grain balance, and found to weigh 1 grain, the counts will be 12½ worsted, because, if 1 yd. weighs 1 gr., 12½ yd. will weigh $\frac{12\frac{1}{2} \times 1}{1} = 12\frac{1}{2}$ gr., which is the yarn weight for worsted. Other counts will reckon in the same proportion.

Loss in Weight. Allowance must be made for the weight the yarn has lost in finishing, and the amount which it has shrunk; sometimes these two neutralise each other. For worsted yarns, 5 per cent. is generally allowed for loss in weight, and 16 per cent. for shrinkage in length and width, according to design used and style of cloth. In woollen yarns, 10 per cent. is generally required to cover loss in weight, and 20 per cent. is sometimes allowed to cover the amount of shrinkage. In cotton yarns, 3 per cent. will often cover loss in weight and shrinkage.

Healding Calculations. These are required by healders or drawers-in. If it is required to draw a warp in to eight shafts, 64 ends per inch straight draft, 64 must be divided by 8 to find the number of mails required on each shaft, which in this case is eight.

But if a warp has to be drawn as the following draft [1] with 64 ends per inch, a different calculation is necessary, because the numbers of mails on each shaft are not all alike.

1

On the first, second, fourth, fifth, and eighth shafts there are six ends in one repeat of draft on each shaft.

On the third and seventh there are seven ends.

On the sixth shaft there are four ends.

Now, to find how many mails per inch is required on each shaft, the following calculation is necessary:

$$\frac{\text{Ends per in.} \times \text{number of ends on shaft in one repeat of draft}}{\text{Number of ends in one repeat of draft}} = \left\{\begin{array}{l}\text{Number}\\ \text{of mails}\end{array}\right.$$

$\frac{64 \times 6}{48} = 8$ mails per in. on Nos. 1, 2, 4, 5, and 8 shafts = 40

$\frac{64 \times 7}{48} = 9\frac{1}{3}$ mails per in. on Nos. 3 and 7 shafts = $18\frac{2}{3}$

$\frac{64 \times 4}{48} = 5\frac{1}{3}$ mails per in. on No. 4 shaft = $5\frac{1}{3}$

Total mails per in. .. 64

Structure of Plain Cloth. This is shown by this cross-section [2] through the warp; the dots represent ends in warp, and the line picks in weft.

This is represented on design paper as shown in 3, which is complete on two ends and picks, with black squares for warp, and white squares for weft.

This design is used a great deal in the cotton trade and low woollens with cotton warp and woollen weft, and also in light-weight suitings for the warmer parts of the world. It is the simplest of all designs and can be woven on two shafts, but its structure is different from all other cloths, because each end is working opposite its neighbour, and the same with each pick, whereas in other cloths some ends and picks are working alike in some parts of the design.

4

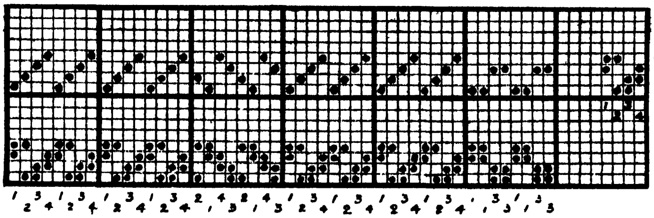
5

Structure of Twill Cloth. This is shown by cross-section [4], through the warp: this is 2—2 twill, and is probably the most generally used design for suitings in all the world, and is represented on design paper as in **5**.

Principles of Drafting. It is possible to get a large variety of designs on four or eight shafts with this design, when the "Principles of Drafting" are understood as explained below. If **6** design was woven in a straight draft it would take 48 shafts to weave it, because this number constitutes one repeat. By taking the ends vertically, and numbering those ends which work alike with the same number it is possible to draft it to weave on four shafts, as **7**.

7

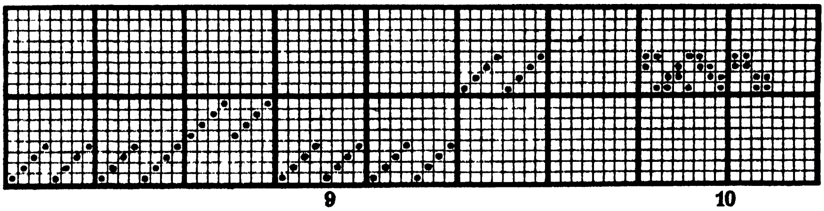
6



8

Figure **8** is the pegging plan, and is composed of the four different kinds of ends in the draft **7**.

The same result may be arrived at by drafting it as **9**, with **10** as pegging plan. The draft has the advantage of being able to weave a straight draft or a combination of small effects, as **10**.

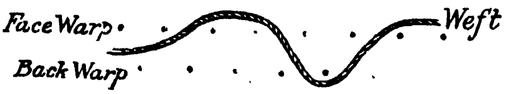


9

10

Structure of Double Cloths. A thorough knowledge of double cloths is invaluable to the textile designer; cloths of this kind may be allowed to have both sides alike, or totally different.

The simplest kind of double cloths are those which are backed with warp, but single in weft,



11

or vice versâ. Figure **11** is cross-section through warp of a cloth backed with warp, 2—2 twill face, eight-end sateen back. The top line of dots represents face warp, and bottom line of dots back warp, and the line represents weft.

Binding of Double Cloths. In binding cloths together with warp, a backing end should always be brought up at the point of binding between two face ends and over a face pick of weft, and so with every pick throughout the design. In all double cloths the binding point should always be concealed as much as possible; and, also, whenever possible, they should be distributed on a sateen basis.

Figure **12** is face design for above cross-section, **13** is back design for above cross-section, including binding, and **14** is face and back design combined end and end on above principles, and is complete.

12

13

Contraction in Weaving. A cloth made with **13** design should have two warps to weave from, one for face cloth, and one for back cloth, owing to the different contractions in weaving of face design and back design. The face weave 2—2 twill will contract about $\frac{1}{11}$th and the back weave about $\frac{1}{20}$th during weaving. So that if the face warp is made 70 yd., the back warp should be 66⅔ yd. Now, if the face warp contracts $\frac{1}{11}$th of 70, it will give 63⅓ yd. out of loom; if the back warp contracts $\frac{1}{20}$th of 70, it will give 63⅓ yd. out of loom, less 1 yd. allowed for waste in starting and for warp left in gear = 62½ yd. out of loom proper.

This contraction is due to the fact that in weaving it is necessary to interlace the warp with the weft at certain places throughout the design, and the more interlacing we have the less ends and picks we can get into the cloth. In the 2—2 twill there are four intersections of weft with warp in eight ends; when this is worked out in a geometrical problem, it gives the answer that 5·464 ends will occupy the space which six diameters of yarn would occupy if there were no interlacing of warp with weft. This is equal to a take-up of $\frac{1}{11}$th.

And, similarly, in the eight-end sateen, there are two intersections of weft with warp in eight ends, which gives the answer that 9·464 ends will occupy the space which 10 diameters of yarn would occupy if there were no intersecting of weft and warp. This is equal to a take-up of $\frac{1}{20}$th.

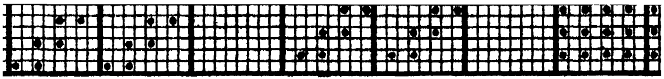
Double Cloth in Warp and Weft. To make this kind of design many designers shade their design paper as **15**; then the black squares represent the face ends and picks, and the darkest squares the backing ends and picks.

A double cloth design with the 2—2 twill face and back, and bound in the eight-end sateen order is shown complete in **20**.

First, the face weave is put on the blank squares in **16**.

Secondly, the back weave is put on the darkest squares as in **17**.

15



16 17 18

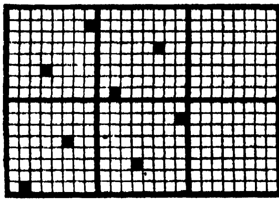
Thirdly, all the face ends are lifted up when each backing pick goes in, as in **18**.

Fourthly, the binding weave is put on as in **19**, which is the eight-end sateen.

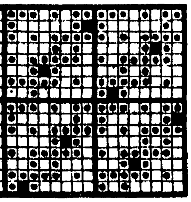
But before this is put on, the proper place for binding must be selected to bring a backing end up between two face ends over a face pick.

These are all combined in **20**, which makes a complete double cloth design 2—2 twill face and back. This design is bound in exactly the same way as **14**, but has a backing weft added.

If **19** was left off **20**, there would be two separate cloths woven, one upon the other, but this is put on to bind the face and back cloths together. A sateen weave should always be used for binding, so that it gives an all-over effect instead of running in twill order.



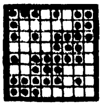
19



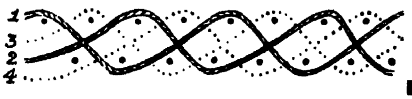
20

Figure **21** is the 2—2 twill face and back, bound in the four shaft twill weave, and can be woven on eight shafts. Cloths woven on either of the two designs can be woven from the warp beam, because the face ends and backing ends have practically the same intersections. Figure **21** will give a much harder cloth than **20**, because the two cloths are more firmly bound together.

Double Plain Cloth. Figure **22** is cross-section of this kind of cloth through the warp, and is bound together by every pick of weft passing from face to back and back to face; the top line of dots are face warp and bottom line of dots are back warp.



21



22

Figure **23** is design for above cross-section, and is largely used in the making of some classes of "West of England" hairline trouserings.

If a warp was made in this design and warped

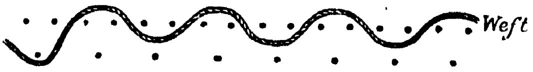
$$\left.\begin{array}{l}\text{White } 1\ 2\ 1\\ \text{Black } 2\ 2\end{array}\right\}\text{ and woven }\begin{array}{c}2\\2\end{array}$$

it would show unbroken lines of white and black running the length of the piece alternately on both face and back of cloth, and the cloth is also very firmly bound.

24

A sample of this cloth is shown in **24** in grey and black.

Two-face and One-back Cloths. A large variety of lined cloths is made for overcoatings with the 2—2 twill face and plain design for lining, with two ends and picks of face to one end and pick of backing; the back can be made plain, striped, or checked, without interfering with the face cloth. Figure **25** is a cross-section through warp with a face pick.



25

Figure **26** is the design for this if woven in a straight draft on 24 shafts, and is made in the same way as **20**. The dots outside the design indicate which are the backing ends and picks; this kind of design is generally begun—one face, one back, one face, in both warp and weft.

If it is required to make this design on less than 24 shafts, it can be drafted on to 16 shafts by putting face weave on the first eight shafts and back weave on last eight shafts, as in **26** draft, with **27** as pegging plan.

The same rules must be observed in this design as when making **20** design. Figure **26** is also bound in the eight-end sateen order [**19**].

Overcoating Cloth. A good medium-weight overcoating cloth can be made with this design to the following particulars, 72 ends and picks per inch, 66 in. wide in loom, one beam.

FACE WARP.

White and black twist worsted 2/36	1	1	1	1
Black worsted 2/36	3	3	3	3

BACK WARP.

White spun silk 18/2 ..	1		1		1		1		1		1	= 4
Black worsted 2/36 ..	1	1	1	1	1	15	1	1	1	1	15	
Blue spun silk 18/2 ..	1		1									
Green spun silk 18/2 ..							1		1			

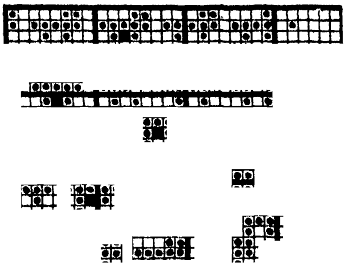
This will give a neat stripe effect on the face cloth and a fancy striped lining with silk ends for striping, while the face cloth and lining will be bound securely together during weaving.

23

All students in the textiles should study various branches of it, because it frequently happens that they sometimes see things in other branches which they can make useful to them in their own branch of the trade. A student of decorative textiles will often derive great benefit by visiting an art exhibition both for design and colour; similarly, a student in the woollen and worsted trades may often learn something by examining samples of the fancy cotton trade.

The designer, manager, and those who assist them should all work in harmony to seize all the advantages of all branches of the trade in getting new ideas, making the proper article for the proper market, and in using the best machinery and the best method of making what is required. Before beginning to make the patterns, the traveller, designer, and assistants should consult together as to what is to be made, and when they have settled what to make they should all try to make something better than has been made before, but always remembering the proper service for which it is made, and to get it in the proper market and at the proper time, not too late and not too soon.

Requirements of a Designer. The textile designer must have a good knowledge of calculations and colour, and remember that ideas beget ideas, and also that his present knowledge must forge the links of connection between what has been already accomplished and what is now required.



26

He should be a keen observer, because in the field of observation chance favours only those who are prepared; and, lastly, he should possess self-reliance, fertility of resource, fearlessness of responsibility, and the power of his own initiative, and be able to apply all the best points of his education in his daily work.

A large quantity of patterns for showing purposes are still produced in the hand looms of Yorkshire, owing to the fact that no box-chain is required for patterns which are checked with weft, as this is done by the weaver he goes on with his work. Of late years there have been many improvements in looms for fancy weaving in suitings; and the year 1906 has been the advent of the new Dobeross loom, made by Hutchinson, Hollingworth & Co., which runs at the rate of 100 picks a minute. There are now hundreds of these looms running in the West Riding of Yorkshire which are doing their work wonderfully well. There is still room for improvement in the finishing machinery because the required finish cannot always be got the first time goods are finished. When this is the case the work has to be gone through again, causing inconvenience and expense.

27

Textile Books. The following list of books is useful for students in the various branches of the textile trade:

"Colour in Woven Design," by R. Beaumont (Whittaker. 21s.); "Woollen and Worsted Cloth Manufacture," by R. Beaumont (Whittaker. 7s. 6d.); "Cotton Spinning," by R. Marsden (Whittaker. 6s. 6d.); "Cotton Weaving," by R. Marsden (Marsden, Manchester. 10s. 6d.); "Pattern Analysis," by A. F. Barker (Marsden. 5s.); "Cotton Spinning Calculations," by W. H. Cook (Marsden. 2s.); "Colour," by G. H. Hurst (Marsden. 7s. 6d.); "Neville's Student's Handbook of Practical Fabric Structure," by Neville (D. W. Textile Classes. Many students attend the technical classes in textile manufacturing towns in Yorkshire and Lancashire. The Yorkshire schools are mostly devoted to woollen and worsted, while those in Lancashire concern themselves with cotton. Leeds University is probably the finest equipped textile school in the world, and contains the required machinery for all the processes from the raw material to the finished cloth. The technical schools of Halifax, Bradford, and Huddersfield are also well equipped, although not to the extent of Leeds. Generally, they have both day classes and evening classes. The latter are attended by persons who work in the daytime who desire to improve their textile knowledge and take up more important positions. A student should be well grounded in arithmetic before he attends these classes; otherwise he will be much hindered in his work.

A student attending the day classes should have two or three years of practical work in a mill. He can then combine the best points of school knowledge with the best practical knowledge gained in the mill. If he has not had this practical experience he may make serious mistakes when he has taken a position outside the school. The students in the spinning department have the facilities of putting their theoretical knowledge into practical certainty on the machinery, making their own calculations and setting the machines accordingly, while the teacher puts them right and explains any errors. They are then accepted for examination in practical work by the City and Guilds of London. The courses are for three or four years, with examinations at the end of each year, when certificates are awarded to those who pass. The International Correspondence Schools of 57-60, Chancery Lane, London, W.C., have now a textile correspondence department.

THE ARTICLE—continued

Agreement of the Article

1. The article agrees in gender and number with the noun which it precedes: *Le cœur, l'esprit, les mœurs, tout gagne à la culture*, the heart, the mind, manners, everything is improved (gains) by culture.

2. The plural article *les* is occasionally used before a proper noun in the singular, merely for the sake of emphasis, and without reference to more than one person of the same name: *Les Corneille, les Racine et les Molière ont illustré la scène française*, Corneille, Racine, and Molière have made the French stage illustrious.

3. The feminine article *la* is used before a saint's name in the masculine, to indicate the day on which that saint's feast is celebrated. In that case, the article agrees with the word *fête* understood: *Je vous payerai à la Saint-Michel prochaine*, I shall pay you next Michaelmas.

4. The feminine article is used before a masculine noun—generally a proper noun—to indicate some special fashion or manner. The word *mode* or *manière* is then understood, and the article agrees with it: *Il a la barbe taillée à la Henri IV.*, His beard is cut after the fashion of Henry IV.

Repetition of the Article

1. The article, whether definite or indefinite, must be repeated before every substantive: *Il a les traits, les regards et la démarche de son père*, He has the features, looks, and demeanour of his father.

2. The use of a single definite article in the plural is customary in certain cases where two or more nouns form an indivisible expression, or unite to constitute a single, definite collection: *École des Arts et Métiers*, School of Arts and Trades. *Les officiers, sous-officiers et soldats*, the officers, non-commissioned officers, and men.

3. When nouns are joined by the conjunction *ou* (or), each of them requires the article, unless the second be synonymous with the first, or an explanation of it: *Le père ou le fils nous écrira demain*, The father or the son will write to us to-morrow. *Les collines ou petites montagnes sont couvertes d'arbres*, The hills or small mountains are covered with trees.

4. When several adjectives joined by *et* refer to the same noun, the article must be used before each of them if the noun indicates several persons or objects: *Les riches et les pauvres seront tous jugés selon leurs œuvres*, The rich and poor will all be judged according to their works.

5. If the several adjectives qualify the same person or object, one article only is required: *Je viens de finir le troisième et dernier volume de ce roman*, I have just finished the third and last volume of that novel.

Ellipsis of the Article

1. The article is frequently omitted in proverbial expressions:

> *Patience et longueur de temps*
> *Font plus que force ni que rage;*
> Patience and perseverance (length of time)
> Achieve more than strength or fury.

NOUNS

I. Nouns of Double Gender

1. There are a few substantives which are either masculine or feminine, with a modification, or only a slight difference of meaning:

(*a*) AMOUR, love, is usually masculine, both in the singular and the plural: *L'amour du jeu réunit tous les autres amours*, The love of gambling comprises all other passions (loves).

In the plural it is feminine when used to designate the passion of love, in the more restricted sense, and when used as "amours" in English. *On retourne toujours à ses premières amours*, We always return to our first love.

(*b*) COUPLE, couple, is masculine when it is applied to two persons between whom their exists a bond of sentiment, similarity of object, etc. It is feminine when meaning simply two, a brace: *Ce serait dommage de séparer un si beau couple*, It would be a pity to separate such a handsome couple. *Une couple d'œufs suffira pour mon déjeuner*, A couple of eggs will suffice for my breakfast.

(*c*) DÉLICE, delight, pleasure, is masculine when used in the singular, and feminine when used in the plural. The meaning is practically the same in both instances: *C'est un grand délice de faire des heureux*, It is a great pleasure to make people happy; *Il fait toutes ses délices de l'étude*, He makes study his whole delight.

(*d*) FOUDRE, thunderbolt, is feminine when used in its literal sense, and masculine when applied figuratively to a great warrior or a great orator. *Cet arbre a été frappé de la foudre*, That tree has been struck by a thunderbolt (lightning). *On dit, au figuré, un foudre de guerre, un foudre d'éloquence, pour désigner un guerrier à qui rien ne résiste, un orateur véhément*, We say, figuratively, *un foudre de guerre, un foudre d'éloquence*, to designate a warrior whom nothing can withstand, a vehement orator.

(*f*) HYMNE is feminine when it means a church hymn, and masculine in any other sense: *Les anciennes hymnes de l'Église ont le mérite de la simplicité*, The old hymns of the Church have the merit of simplicity; *Chaque peuple a son hymne national*, Every nation has its national anthem.

(*g*) ŒUVRE, work, is usually feminine. It is sometimes masculine in poetical language, or when it has the special meaning of "the search for the philosopher's stone" or of the collected works of an engraver or of a composer: *Ce volume contient les œuvres complètes de Corneille*, That volume contains the complete works of Corneille.

(*h*) GENS, people, requires words in agreement with it to be feminine if they precede and masculine if they follow it: *Ce sont les meilleures gens que j'aie jamais vus*, They are the best people I have ever seen.

But words in agreement with *gens* are always masculine, if they occur in a separate clause, whether before or after it: *Instruits par l'expérience toutes* *les vieilles gens sont soupçonneux*, Taught by experience, all old people are suspicious.

"All" must be translated by the masculine form *tous* when it accompanies an adjective having but one form for both genders and preceding *gens*: *Tous les honnêtes gens*, all honest people.

Tous must also be used, even when it precedes *gens*, if *gens* is followed by an adjective or past participle: *Tous les gens sensés*, all sensible people.

2. The following nouns have a different meaning according as they are of the masculine or of the feminine gender:

aide (m.), a person who helps
aide (f.), help, assistance
aune (m.), alder-tree
aune (f.), ell
cerise (m.), cherry-colour
cerise (f.), cherry
crêpe (m.), crape
crêpe (f.), pancake
critique (m.), critic
critique (f.), criticism
enseigne (m.), ensign, standard-bearer
enseigne (f.), standard, signboard
faux (m.), forgery
faux (f.), scythe
fourbe (m.), rogue
fourbe (f.), imposture
greffe (m.), record office (of a court of law)
greffe (f.), grafting
guide (m.), guide
guide (f.), guiding-rein
livre (m.), book
livre (f.), pound
manche (m.), handle
manche (f.), sleeve; *Manche* (f.), Engl. Channel
manœuvre (m.), workman, mechanic
manœuvre (f.), manœuvre
martyre (m.), martyrdom
martyre (f.), female martyr
mauve (m.), mauve colour
mauve (f.), marsh-mallow
mémoire (m.), memoir, bill
mémoire (f.) memory
mode (m.), mood, manner
mode (f.), fashion
mort (m.), dead man
mort (f.), death
moule (m.), mould, model
moule (f.), mussel (shell-fish)
mousse (m.), cabin-boy, ship-boy
mousse (f.), moss
office (m.), office, service, functions
office (f.), pantry, servants' hall
orange (m.), orange colour
orange (f.), orange
page (m.), page (attendant)
page (f.), page (of a book)
paillasse (m.), clown
paillasse (f.), straw mattress
paille (m.), straw-colour
paille (f.), straw
parallèle, (m.) parallel (comparison)
parallèle (f.), parallel line
pendule (m.), pendulum
pendule (f.), timepiece
physique (m.), the physique of a person
physique (f.), physics, natural philosophy
pique (m.), spade (a suit of cards)
pique (f.), pike
poêle (m.), stove, pall, canopy
poêle (f.), frying-pan
politique (m.), politician
politique (f.), politics, policy
poste (m.), post, situation, guard-house
poste (f.), letter-post, stage-post
rose (m.), rose-colour, pink
rose (f.), rose
solde (m.), balance of an account
solde (f.), pay (military)
somme (m.), nap, sleep
somme (f.), sum, total
tour (m.), turn, circuit, trick, lathe
tour (*f*), tower
trompette (m.), trumpeter
trompette (f.), trumpet
vapeur (m.), steamer
vapeur (f.), vapour, steam
vase (m.), vase, vessel
vase (f.), ooze, mud
voile (m.), veil
voile (f.), sail

II. Compound Nouns

1. Compound nouns written without a hyphen are considered single words, and form their plural according to the general rules: *un chèvrefeuille*, a honeysuckle plant; *des chèvrefeuilles*, honeysuckle plants.

Exception: In the following words, the components, though not joined by a hyphen, both take the plural form:

un bonhomme, an old fellow, etc.; *des bonshommes*, old fellows, etc.

un gentilhomme, a nobleman; *des gentilshommes*, noblemen.

monseigneur, my lord; *messeigneurs*, my lords. And similarly, *monsieur*, *messieurs*; *madame*, *mesdames*; *mademoiselle*, *mesdemoiselles*.

2. When a compound noun consists of two nouns joined by a hyphen, both the components take the mark of the plural:

un chou-fleur, a cauliflower; *des choux-fleurs*, cauliflowers.

un oiseau-mouche, a humming-bird; *des oiseaux-mouches*, humming-birds.

un timbre-quittance, a receipt-stamp; *des timbres-quittances*, receipt-stamps.

un timbre-dépêche, a telegraph-stamp; *des timbres-dépêches*, telegraph-stamps.

Exception: In the following compound words, the first of the components is the only one that takes the mark of the plural:

appui(s)-main, maul-stick, rest for the hand; *hotel(s)-Dieu*, hospital; *reine(s)-claude*, greengage; *timbre(s)-poste*, postage-stamp; *mandat(s)-poste*, post-office order.

3. When a compound noun consists of two nouns joined by a preposition, the first noun alone takes the sign of the plural:

un arc-en-ciel, a rainbow; *des arcs-en-ciel*, rainbows.

un chef-d'œuvre, a masterpiece; *des chefs-d'œuvre*, masterpieces.

un cul-de-jatte, a cripple; *des culs-de-jatte*, cripples.

Exception: In the following words, the sense requires both components to remain invariable, even when the whole compound is in the plural:

un (des) coq-à-l'âne, a rambling story; *un (des) pied-à-terre*, temporary quarters; *un (des) pot-au-feu*, broth; *un (des) tête-à-tête*, private interview.

4. When a compound consists of a noun and an adjective, both components take the sign of the plural:

une eau-forte, an etching; *des eaux-fortes*, etchings.

un coffre-fort, a strong-box; *des coffres-forts*, strong-boxes.

une claire-voie, lattice, wicket; *des claires-voies*, lattices, wickets.

Exception: The second component alone takes the sign of the plural in (*a*) all the feminine words consisting of *grand'* and a noun, as *grand'mère*, grandmother, *grand'mères*, grandmothers; and in (*b*) the three words *chevau-léger*, a light horseman, *terre-plein*, an earthern platform or terrace, and *sauf-conduit*, a safe-conduct, of which the respective plurals are: *des chevau-légers*, *des terre-pleins*, and *des sauf-conduits*.

5. In compound nouns made up of a verb and of a noun, only the noun can take the sign of the plural:

un passe-port, a passport; *des passe-ports*, passports.

NOTE. In compound nouns of this kind, it frequently happens that the noun-component (*a*) remains in the singular when the whole compound is in the plural, or (*b*) is in the plural whether the whole compound be in the singular or in the plural:

(*a*) *un abat-jour*, a lamp-shade
des abat-jour, lamp shades
un casse-cou, a break-neck place
des casse-cou, break-neck places
un coupe-gorge, a cut-throat place, den
des coupe-gorge, cut-throat places, dens
un porte-monnaie, a purse
des porte-monnaie, purses
un réveille-matin, an alarum
des réveille-matin, alarums

(*b*) *un brise-lames*, a breakwater
des brise-lames, breakwaters
un porte-clefs, a turnkey
des porte-clefs, turnkeys
un serre-papiers, a paperweight
des serres-papiers, paperweights
un casse-noisettes, a nut-cracker
des casse-noisettes, nut crackers
un porte-lettres, a letter-rack
des porte-lettres, letter-racks
un couvre-pieds, a foot-coverlet
des couvre-pieds, foot-coverlets

There are, however, some cases in which the analysis of the word may be made to justify either the singular or the plural form of the noun-component, and we find authorities giving both *un porte-plume*, a penholder, *des porte-plume*, penholders, and *un porte-plumes*, *des porte-plumes*.

6. When *garde* is the first part of a compound word, it usually takes the sign of the plural if it denotes a person: *une garde-malade*, a sick-nurse; *des gardes-malades*, sick-nurses.

If it denotes an object, it commonly remains invariable: *une garde-robe*, a wardrobe; *des garde-robes*, wardrobes.

7. In compound nouns consisting of an adverb and a noun, or of a preposition and a noun, the noun usually takes the mark of the plural:

une arrière-petite-fille, a great-granddaughter; *des arrière-petites-filles*, great-granddaughters.

un avant-coureur, a fore-runner; *des avant-coureurs*, fore-runners.

un contre-amiral, a rear-admiral; *des contre-amiraux*, rear-admirals.

8. When a compound noun is made up of invariable words—*i.e.*, verbs, numerals, prepositions, adverbs—the components remain unchanged:

un passe-partout, a master-key; *des passe-partout*, master-keys.

un in-douze, a duodecimo: *des in-douze*, duodecimos.

III. Proper Nouns

1. Names of persons do not usually take the sign of the plural: *Les deux Corneille étaient frères*, the two Corneilles were brothers.

Exceptions: (*a*) When a proper noun is used to indicate, not one person, but several persons resembling the bearer of that name, the proper noun takes the sign of the plural: *Un Auguste aisément peut faire des Virgiles*, An Augustus can easily produce Virgils—*i.e.*, poets like Virgil.

(*b*) Proper nouns common to a whole race, dynasty, etc., take the sign of the plural: *Deux des Stuarts ont péri sur l'échafaud*, Two of the Stuarts perished on the scaffold.

(*c*) When the name of an author or of a painter is used to indicate copies or examples of his works, it is treated as a common noun, and takes the sign of the plural accordingly: *J'ai plusieurs Virgiles dans ma bibliothèque*, I have several Virgils in my library.

2. Proper names of countries take the sign of the plural: *Nous avons visité les Indes occidentales et les deux Amériques*, We have visited the West Indies and the two Americas (North and South).

IV. Foreign Nouns

1. Foreign words that have become naturalised as French nouns, form their plural in the usual way: *Un accessit*, an honourable mention; *des accessits*, honourable mentions; *un tory*, a Tory; *des torys*, Tories.

2. Most Latin compounds used in French are invariable: *un post-scriptum*, a postscript; *des post-scriptum* postscripts; *un ex-voto*, a votive offering: *des ex-voto*, votive offerings.

3. Prayers, hymns, etc., are frequently indicated by their Latin beginning, which remains invariable when used as a plural noun: *un Te Deum*, a Te Deum; *des Te Deum*, Te Deums.

KEY TO TRANSLATION

GEOGRAPHY OF THE FRENCH LANGUAGE

The French language comprises the whole domain of modern France, with the exception of a single province, Brittany, where a million inhabitants out of 1,800,000 speak a language known under the name of Low Breton (and) which is of Celtic origin. To this important exception we may add further three little groups—the Department of the North, where 200,000 inhabitants (out of 1,200,000) speak the Flemish language, which is of German origin; the Department of the Lower-Pyrenees, where 120,000 inhabitants speak Basque, a very ancient dialect, of which the origin is unknown; finally, the Department of the Eastern-Pyrenees (the former province of Roussillon), where 130,000 inhabitants speak the Catalonian language, which is derived from Latin.

If the domain of the French language does not extend over the whole of the present territory of France, by way of compensation it comprises abroad several important territories, representing a little more than 3,600,000 inhabitants, divided thus: for Belgium, 1,600,000 inhabitants; for the Empire of Germany, 1,000,000 (Alsace-Lorraine); for French Switzerland, 400,000; lastly, 60,000 for the Channel Islands, which belong to England.

To these figures there must be added, outside of Europe, the English colonies of Canada and of the Island of Mauritius, which have retained the use of French, without speaking of our own colonies (Algeria, Guiana, Senegal, etc.). This is a balance of rather more than 1,500,000 to be added to the French linguistic domain.

Familiar Dialogues	Dialogos Familiares
Who knocked at the door ?	¿ Quien ha llamado á la puerta ?
The countess's footman, with a note	El lacayo de la señora condesa con una esquela
Bring it here	Traígala
He will not deliver it excepting into your own hands	No quiere sino entregarla en manos propias
Show him in	Hágale pasar
Good-day, madam	Buenos dias, señora.
How are you ?	¿ Como esta Vd ?
Middling. Sit down	Regular, tome Vd asiento

Thanks. I came to say good-bye. I am leaving to-morrow for Paris	Gracias. Vengo á despedirme ; salgo mañana para Paris
Are you going alone ? Is not your wife going with you ?	¿ Va Vd solo ? No va su Sra. con Vd ?
No ; her health does not permit it	No ; su salud no se lo permite
I am very sorry	Lo siento mucho
How pleased I am that you have called at this hour. Now that you are here, you will stay and dine with us ?	Cuanto me alegro verle llegar á esta hora. ¿ Ahora que está Vd aquí se quedará á comer con nosotros ?
I appreciate the invitation, but I cannot accept it. If you were alone it would not matter, but I really cannot sit down to table with the marchioness in these clothes	Agradezco la invitacion pero no puedo aceptarla. Si estuviera Vd solo no importaría pero en verdad no puedo sentarme á la mesa con la señora marquesa en este traje
What does it matter, man ! My wife will excuse you	¡ Hombre, que importa ! Mi señora dispensará á Vd
Is the post in ?	¿ Ha llegado el correo ?
Yes, sir. Here are the letters. It seems that the post is only for circulars and advertisements. I have four here	Si, señor. Aqui están las cartas. Parece que no viene el correo mas que para traer circulares y anuncios, aqui tengo cuatro
Where is the secretary ?	¿ Donde está el secretario ?
We have a great deal to write ; it is mail day	Tenemos mucho que escribir ; es dia de correo
What day of the month is it ?	¿ A cuanto estámos del mes ?
Address these letters ; these four must be sealed. The sealing-wax is in that box with the stamps	Dirija estas cartas ; estas cuatro necesitan sellarse. El lacre está en aquella caja, con los sellos de correo
Breakfast is served, madam	Señora el almuerzo está servido
Tell the master	Avise al amo
He is in the dining-room, and the young lady and young gentleman have also come down	Está en el comedor, y tambien han bajado la señorita y el señorito
Good-morning, mother	Muy buenos dias madre
Good-morning, children	Muy buenos dias hijos
What have we for breakfast ?	¿ Que tenemos para almorzar ?
In this dish here there are eggs and ham, and over there are kidneys, which look very good, and there is cod in front of Papa	Aqui en esta fuente hay huevos y jamon, y allá hay riñones que parecen estar muy buenos y delante de papá hay merluza
What will you take, chocolate or coffee ?	¿ Que vas à tomar chocolate ó café ?
I will take tea	Tomaré té
Where shall we go today ?	¿ Dondo irémos hoy ?
We have to go to the dressmaker and to the milliner, and then we will go for a walk until it is time to fetch your father from the office, and I suppose you remember that to-night there is the ball at the Embassy	Tenemos que ir á la costurera, y á la modista, y despues irémos á dar un paseo hasta que sea hora de ir á buscar á tu padre á la oficina, y yá supongo que no te olvidas que esta noche es el baile de la Embajada
Of course, I remember	Porsupuesto que me acuerdo
Give me two first-class tickets to Z. I am going to register the luggage. Be quick so as to get a seat near the door	Déme Vd dos billetes para Z. de primera clase. Voy á facturar el equipaje. Darse prisa para coger un asiento de portezuela
I want to be with my face to the engine, otherwise, as you know, I get giddy	Quiero ir de cara á la locomotora ; ya sabes que de otro modo me mareo
At the next station we will buy a small basket of provisions, what the English call a lunch basket	En la proxima estacion comprarémos una canastita con provisiones, lo que llaman los ingleses " a lunch basket "
They told me that before reaching Z. we have to pass through a tunnel	Me dijeron que antes de llegar á Z. teniámos que pasar por un túnel
Yes, and we have already reached it, but we shall soon come to the other end, and at the same time to the stopping place	Si, y ya hemos llegado a él, pero pronto llegarémos al otro lado, y al mismo tiempo al apeadero
And shall I find what I require at this office ?	¿ Y encontraré alli lo que necesito ?
It is possible, but it is difficult to find good servants	Puede ser, pero el encontrar buenos criados es muy dificil
COMMERCIAL PHRASEOLOGY AND VOCABULARY	FRASEOLOGIA COMERCIAL Y VOCABULARIO
The market is gradually giving way	El mercado baja gradualmente
The prospects for almonds this year are not favourable	Nada favorable es el aspecto que presentan las almendras este año
Prices for coffee are easier	Los precios para el café han cedido algo
The market is very depressed	El mercado está muy abatido ó flojisimo
A fall is not to be expected	No es de esperar una baja
More attention is paid at the present moment to other articles	En la actualidad se fija principalmente la atencion en otros articulos
A small lot has been disposed of at high prices	Se acaba de colocar un pequeño lote á precios altos
The market closes firmly	El mercado cierra firme
A few transactions have been effected at somewhat low prices	Algunas operaciones se han efectuado à tipos algo bajos
The steamer sailed last week for America, carrying a big cargo	El buque salió para America la semana pasada conduciendo un cargamento grande
Our neighbouring markets have been affected by the decline	La baja ha dejado sentir su influencia en los mercados inmediatos ó vecinos
We are completely bare, without any stock	Nos encontramos desprovistos, limpios de existencias
Our market is glutted with pears	Nuestro mercado està abarrotado de peras

What little is left unsold is eagerly bought	Lo poco que queda disponible se compra con afán
Some fresh supplies have appeared in the market	Hemos vuelto à tener nuevas entradas ó arribos
We had to force sales, and this had a bad effect all round	Nos vimos precisados à forzar ventas y el efecto en general fué adverso
It is rumoured that a well-known and long-established firm of our city is in difficulties	Corren rumores de que una casa de años establecida en nuestra ciudad, y bien conocida, se halla en dificultades
There are still some wants to be supplied	Hay aun algunas necesidades por cubrir
It is an article very highly thought of in our city	Es un articulo muy apreciado en nuestra plaza
A house is in treaty for a parcel of nuts	Una casa tiene pendiente de trato una partida de avellanas
Contracts for February delivery have been made	Se han hecho algunas contratas para entrega en Febrero
Retail sales	Ventas al detalle
The expected improvement has not yet taken place	La mejora esperanzada no se ha realizado todavia
This state of things is against business being done	Este estado de cosas entorpece las operaciónes
Business is reviving	Los negocios van cobrando vida
A considerable excitement has prevailed during the last fortnight	Ha reinado muchisima agitacion durante la ultima quincena
This invoice has not yet been paid	Esta factura no está aun pagada
Silver is quoted at a very low figure to-day	El valor de la plata hoy dia es muy bajo
The doubtful state of things	El estado dudoso ó incierto de cosas
This is an auction day	Este es dia de subasta
It is impossible to execute orders all at once	No es posible cumplimentar en el acto, todas las ordenes
We are inclined to believe that prices have reached their minimum	Creemos que los precios han visto ya su minimum

The letter-box	El buzon
The Custom House	La Aduana
The bank	El banco
A promissory note	Un pagaré
The packages	Los bultos ó paquetes
The cash-box	La caja de fondos
The warehouse	El almacen
The red ink	La tinta roja
The book-keeper	El tenedor de libros
The gum-pot	El pote de la goma
The message	El recado
The trade mark	La marca de fábrica
The workshop	El taller
The appointment	La cita
The clerk	El dependiente
The telephone	El teléfono
The telephone exchange	La central
The lift	El ascensor

KEY TO EXERCISE XXI. (1)

1. Mas vale tarde que nunca, pero mas vale pronto que tarde. 2. Les mandé dinero para que pudieran costearse el viaje, y á menos que lo reciban á tiempo, temo que no tendrémos el gusto de verlos. 3. Bien que le advertí que la especulacion era arriesgada, metió grandes sumas en esa empresa, y en caso que haga bancarrota, tendré que salir garante, puesto que es mi hermano. 4. ¿ Hola amigo, como va ? Hace tiempo que no le he visto. 5. Ya que no quiere Vd venirme á ver, aqui estoy yo, por aquello que se dice que si la montaña no viene á Mahoma, Mahoma viene á la montaña.

KEY TO EXERCISE XXI. (2)

1. That man is very tall—too tall, in my opinion. He is almost a giant. 2. Napoleon was a great man, in spite of being of small stature. 3. Playing the harp hurts the tips of one's fingers. 4. He was a man of learning. He held a chair in the University of Salamanca, and was considered the first professor of that celebrated University. 5. He occupied a very high position: he raised himself from nothing. He was the only one who raised his voice in the defence of the freedom of the Press. 6. Aft - the war the troops made their entrance into the capital amid the great acclamations of the people, and they are going to erect a statue to the general. 7. Mr. So-and-so was irritated this morning. Who is Mr. So-and-so ? I never remember his name.

By Harald Clegg

Pronouns, Adjectives and Adverbs

The student is advised not to attempt to learn the following table by heart as it stands, but to make himself master of the nine distinctive terminations, as shown in column 1, each of which, it will be observed, is carried through the horizontal line quite regularly. Then the powers of the four prefixed parts, *t'*, *k'*, *ĉ'*, and *nen'*, as given in the headings of columns 2, 3, 4, and 5, should be learned so that these may be added to any of the indefinite words in column 1 according to need. Finally the meaning will be readily retained on reading sentences where they occur.

The words in line A, being adjectives, and those in line J, being pronouns, take, if required, the plural and the accusative. Those in line G are essentially pronouns, and, being of a collective character, are always singular, but may, of course, take the accusative.

The five adverbs in line D may also, when motion or direction is indicated, take the final N.

In column 2, the words *tia*, *tie*, *tio*, *tiu* may each have the word *ĉi* placed either before or after them, according to taste. This has the effect of bringing nearer the thing or place.

Example: *Tia*, that kind of; *tia ĉi*, this kind of; *tiaj ĉi*, those kinds of.

Tie, there; *tie ĉi*, here; *tien*, in that direction; *tien ĉi*, in this direction.

Tio, that thing; *tio ĉi*, this thing.

Tiu, that one; *tiu ĉi*, this one; *tiuj ĉi*, these.

ia
tia

TABLE OF CORRELATIVE PRONOUNS, ADJECTIVES, AND ADVERBS.

		INDEFINITE (1)	DEMONSTRATIVE (2)	RELATIVE AND INTERROGATIVE (3)	COLLECTIVE AND DISTRIBUTIVE (4)	NEGATIVE (5)
A	**Quality**	*ia* some kind	*tia* that kind, such	*kia* which kind	*ĉia* every kind	*nenia* no kind
B	**Motive**	*ial* for some reason	*tial* for that reason; therefore	*kial* for which reason; why?	*ĉial* for every reason	*nenial* for no reason
C	**Time**	*iam* at some time	*tiam* then	*kiam* when	*ĉiam* always	*neniam* never
D	**Place**	*ie* somewhere	*tie* in that place; there	*kie* in which place; where	*ĉie* everywhere	*nenie* nowhere
E	**Manner**	*iel* somehow	*tiel* thus; so	*kiel* how; as	*ĉiel* every way	*neniel* nohow
F	**Possession**	*ies* someone's	*ties* that one's	*kies* whose	*ĉies* everyone's	*nenies* no one's
G	**Thing**	*io* something	*tio* that (thing)	*kio* which (thing) what „	*ĉio* everything	*nenio* nothing
H	**Quantity**	*iom* somewhat; a little	*tiom* as much; as many	*kiom* how much how many	*ĉiom* all	*neniom* none
J	**Individual**	*iu* some one	*tiu* that one	*kiu* which, who	*ĉiu* each one	*neniu* no one

Example: *Mi deziras tiajn, kiaj estas miaj*, I want such as are mine.

iam *ĉiam*
tiam *neniam* } *kiam*

Example: *Li salutas ĉiam, kiam li vidas min*, He always salutes when he sees me.

ie *ĉie*
tie *nenie* } *kie*

Example: *Si loĝas tie, kien mi nun iras*, She lives there, where I am now going.

iel *ĉiel*
tiel *neniel* } *kiel*

Example: *Li laboras neniel, kiel vi volas*, He works not at all (nohow) as you wish.

io *ĉio*
tio *nenio* } *kio*

Example: *Jen estas io, kion vi bezonas*, Here is something that you want.

tiom = *kiom*

Example: *Mi prenos tiom, kiom vi posedas*, I shall take as much as you possess.

iu *ĉiu*
tiu *neniu* } *kiu*

Example: *Si dankis ĉiujn, kiuj estis tie*, She thanked all who were there.

The word *ajn* is often used after the tabulated words. It resembles "ever," which is found in the English words "whoever, whenever, wherever," etc., and is used in just the same way, except that it is not joined to the preceding word.

Example: *kiu ajn*, whoever; *kio ajn*, whatever.

When any of the nine words in column 3 are used at the beginning of a sentence to ask a question, the interrogative *ĉu* is not required.

Example: *Kie vi aĉetis tian ĉapelon?* Where did you buy that hat?

All the words in the tables are root words, and the nature of many of them (though not of all) permits the addition of the final *o*, *a*, or *e*.

Example: *Li ĉiame plendas*, He everlastingly complains; *mi ne scias la kialon*, I do not know the reason (the why); *La ĉiea ŝerculo*, the ubiquitous wag.

Vocabulary

Aĝ', age
angul', corner, angle
aper', appear
atak', attack
aŭskult', listen
aŭtun', autumn
barakt', struggle
dat', date (time)
diven', guess

subit', sudden, instantaneous
sufiĉ', sufficient
sukces', success
ten' hold
tir', draw, pull

EXERCISE X.

When you saw him with such a strange person, why did you not speak to me? Which are the four seasons of the year? Spring, summer, autumn, winter. These men, whose conduct I disapproved, suddenly attacked me, five at a time. What (how much) is today's date? Can you guess my age? Where did you throw it? The stone fell there. That is certainly just. I never at any time met your colleagues of whom you speak. How much does this old book cost? Tears fell from her eyes one by one when she heard the reason. I can never pardon (to) them their faults, but when their conduct gains my approval then I will praise them. My memory always to some extent deceives me. The dog that barks loudly never bites. All nations progress, some rapidly, others slowly. The water here is rather deep. That is sufficient. We must work to earn that which it is necessary to have—that is, money. I nowhere and never said such words. I have as many cares as you. Why did you not listen to him? When he heard my voice he stopped, and then for some reason suddenly ran into the house. I want to know what (that which) he said to you about such public matters. Here is somebody's glove. Whose is it ?

KEY TO EXERCISE IX.

Unu jaro havas dek du monatojn ; Julio estas la sepa. Ĝi havas tridek unu tagojn, kaj sekvas Junion. La ceteraj monatoj estas Januaro, Februaro, Marto, Aprilo, Majo, Aŭgusto, Septembro, Oktobro, Novembro, kaj fine griza kaj malluma Decembro. Gefiloj. Gefratoj. Genevoj. Geavoj. Geviroj. Gesinjoroj. Gefianĉoj. Li flatas sin, sed li ne konvinkis min. Ŝi ekridis. Mi ekpensas, ke vi volas trompi min. Mia nepo resendis la leteron al mi. Ŝi skribis sur pecon de papero. Mi serĉis la buteron, kaj fine ĝin trovis sub la ĵurnalo. Mi falis sur miajn genuojn, kaj ĵuris ke mi redonis la monon. Matene oni vidas la sunon en la oriento. Vespere ĝi estas en la okcidento. La kaĝo pendas sur la muro ekster la domo. Ŝi trankvile remetis la fluidon en la botelon. Miaj gekuzoj nutris la fiŝojn. La folio falis de la arbo al la tero. Li falis en la riveron. Ili akompanis min ĝis la teatro. Ili penis konsoli ŝin, sed ne povis. La plej bonaj el ni devos morti kaj reiri al la tero tra la tomboj Terura vento ekblovis kaj la nuboj kaŝis la sunon.

SECTION I. ACCIDENCE

Adjectives: First and Second Declensions. The adjectival endings of the first and second declensions are usually ος, η, ον (masc., fem., neut.). The feminine is declined like a feminine noun of the first declension, and the masculine and neuter like nouns of the second declension. If a vowel or ρ precedes the termination ος, the feminine ends in α, not in η. Thus, σοφός, σοφή, σοφόν (wise) ; ἐχθρός, ἐχθρά, ἐχθρόν (hostile)

Singular

N.	σοφός	σοφή	σοφόν	ἐχθρός	ἐχθρά	ἐχθρόν
V.	σοφέ	σοφή	σοφόν	ἐχθρέ	ἐχθρά	ἐχθρόν
A.	σοφόν	σοφήν	σοφόν	ἐχθρόν	ἐχθράν	ἐχθρόν
G.	σοφοῦ	σοφῆς	σοφοῦ	ἐχθροῦ	ἐχθρᾶς	ἐχθροῦ
D.	σοφῷ	σοφῇ	σοφῷ	ἐχθρῷ	ἐχθρᾷ	ἐχθρῷ

Dual

N. V. A.	σοφώ	σοφά	σοφώ	ἐχθρώ	ἐχθρά	ἐχθρώ
G. D.	σοφοῖν	σοφαῖν	σοφοῖν	ἐχθροῖν	ἐχθραῖν	ἐχθροῖν

Plural

N. V.	σοφοί	σοφαί	σοφά	ἐχθροί	ἐχθραί	ἐχθρά
A.	σοφούς	σοφάς	σοφά	ἐχθρούς	ἐχθράς	ἐχθρά
G.	σοφῶν	σοφῶν	σοφῶν	ἐχθρῶν	ἐχθρῶν	ἐχθρῶν
D.	σοφοῖς	σοφαῖς	σοφοῖς	ἐχθροῖς	ἐχθραῖς	ἐχθροῖς

NOTE. The masculine form of the dual is often used for the feminine, and forms like σοφά and σοφαῖν are rare.

Some adjectives in ος, however, have only two endings, ος and ον, the feminine ending in ος like the masculine—*e.g.*, ἄδικος, ἄδικον, unjust ; ἄλογος, ἄλογον, unreasonable.

Most adjectives ending in εος and οος are contracted, thus: χρυσέος, χρυσέα, χρυσέον, golden, becomes χρυσοῦς, χρυσῆ, χρυσοῦν ; ἀργυρέος, ἀργυρέα, ἀργυρέον, silver, becomes ἀργυροῦς, ἀργυρᾶ, ἀργυροῦν ; and ἁπλόος, ἁπλόη, ἁπλόον, simple, becomes ἁπλοῦς, ἁπλῆ, ἁπλοῦν, in the next column.

There are a few adjectives of the second declension ending in ως (masculine and feminine), ων (neuter), corresponding to the nouns of the Attic declension [see νεώς]. Thus ἵλεως, gracious, is declined in the next column.

Singular

	Masc.	*Fem.*	*Neuter*	*Masc., Fem.*	*Neuter*
N.	ἁπλοῦς	ἁπλῆ	ἁπλοῦν	ἵλεως	ἵλεων
A.	ἁπλοῦν	ἁπλῆν	ἁπλοῦν	ἵλεων	ἵλεων
G.	ἁπλοῦ	ἁπλῆς	ἁπλοῦ	ἵλεω	ἵλεω
D.	ἁπλῷ	ἁπλῇ	ἁπλῷ	ἵλεῳ	ἵλεῳ

Dual

N., V., A.	ἁπλώ	ἁπλά	ἁπλώ	ἵλεω	ἵλεω
G., D.	ἁπλοῖν	ἁπλαῖν	ἁπλοῖν	ἵλεῳν	ἵλεῳν

Plural

N.	ἁπλοῖ	ἁπλαῖ	ἁπλᾶ	ἵλεῳ	ἵλεω
A.	ἁπλοῦς	ἁπλᾶς	ἁπλᾶ	ἵλεως	ἵλεω
G.	ἁπλῶν	ἁπλῶν	ἁπλῶν	ἵλεων	ἵλεων
D.	ἁπλοῖς	ἁπλαῖς	ἁπλοῖς	ἵλεῳς	ἵλεῳς

EXERCISE III.

Turn the following into Greek, remembering that adjective and article must agree with the noun in number, gender, and case :

1. Of the simple girl. 2. To the hostile soldier. 3. Golden gifts. 4. Of the wise young men. 5. The unjust girl (accusative). 6. To the silver sea. 7. Unreasonable laws. 8. Of the wise mind. 9. Of the golden temple. 10. The simple judges (accusative).

Third Declension Nouns: The stems usually ending in a consonant.

The third declension includes all nouns not belonging to one or other of the two previous declensions. The stem of a noun of the third declension is generally found by dropping the termination of the genitive singular ος or ως : thus, λέων, λέοντος, stem λέοντ–.

The cases are formed by adding the following endings to the stem :

	Singular		*Dual*	*Plural*	
	Masc. & Fem.	*Ntr.*	*Masc., Fm., Ntr.*	*Masc. & Fem.*	*Ntr.*
N.	ς	none	ε	ες	α
A.	α or ν	none		ας	α
G.	ος, ως		οιν	ων	
D.	ι			σι	

NOTE. In the nominative singular and dative plural the terminations ς and σι respectively often become united with the last letter of the stem, as φύλαξ, guard, for φυλακ-ς; and dative plural φύλαξι, for φυλακ-σι.

The following are examples of the commonest forms of nouns of this declension with mute or liquid stems :

MASCULINES and FEMININES

ὁ κόραξ, raven ; ἡ μάστιξ, whip ; ὁ λέων, lion.

	Singular		
Nom.	κόραξ	μάστιξ	λέων
Voc.	κόραξ	μάστιξ	λέον
Acc.	κόρακα	μάστιγα	λέοντα
Gen.	κόρακος	μάστιγος	λέοντος
Dat.	κόρακι	μάστιγι	λέοντι
	Dual		
N., V., A.	κόρακε	μάστιγε	λέοντε
Gen., Dat.	κοράκοιν	μαστίγοιν	λεόντοιν
	Plural		
Nom., Voc.	κόρακες	μάστιγες	λέοντες
Acc.	κόρακας	μάστιγας	λέοντας
Gen.	κοράκων	μαστίγων	λεόντων
Dat.	κόραξι	μάστιξι	λέουσι

ὁ παῖς, boy ; ὁ or ἡ ὄρνις, bird ; ὁ γίγας, giant.

	Singular		
Nom.	παῖς	ὄρνις	γίγας
Voc.	παί	ὄρνι	γίγαν
Acc.	παῖδα	ὄρνιν or ὄρνιθα	γίγαντα
Gen.	παιδός	ὄρνιθος	γίγαντος
Dat.	παιδί	ὄρνιθι	γίγαντι
	Dual		
N., V., A.	παῖδε	ὄρνιθε	γίγαντε
Gen., Dat.	παιδοῖν	ὀρνίθοιν	γιγάντοιν
	Plural		
Nom., Voc.	παῖδες	ὄρνιθες	γίγαντες
Acc.	παῖδας	ὄρνιθας	γίγαντας
Gen.	παίδων	ὀρνίθων	γιγάντων
Dat.	παισί	ὄρνισι	γίγασι

In the same way decline the following nouns of this declension :

	Gen. sing.	*Dat. pl.*
ἡ φλέψ, vein	φλεβός	φλεψί
ὁ γύψ, vulture	γυπός	γυψί
ὁ φύλαξ, guard	φύλακος	φύλαξι
ὁ κῆρυξ, herald	κήρυκος	κήρυξι
ἡ πτέρυξ, wing	πτέρυγος	πτέρυξι
ἡ σάλπιγξ, trumpet (pronounced *salpinx*)	σάλπιγγος	σάλπιγξι
ὁ ὄνυξ, nail, claw	ὄνυχος	ὄνυξι
ὁ ἄναξ, chief, prince (poetical voc. ἄνα)	ἄνακτος	ἄναξι
ἡ νύξ, night	νυκτός	νυξί
ὁ γέλως, laughter	γέλωτος	—
ἡ Ἑλλάς, Greece	Ἑλλάδος	—
ἡ κόρυς, helmet	κόρυθος	κόρυσι
ἡ ἐλπίς, hope (voc. ἐλπί)	ἐλπίδος	ἐλπίσι
ἡ λαμπάς, torch	λαμπάδος	λαμπάσι
ἡ πατρίς, native land	πατρίδος	πατρίσι
ὁ ἐλέφας, elephant	ἐλέφαντος	ἐλέφασι
ὁ γέρων, old man (voc. γέρον)	γέροντος	γέρουσι
ὁ ὀδούς, tooth	ὀδόντος	ὀδοῦσι
ὁ ποιμήν, shepherd	ποιμένος	ποιμέσι
ὁ λιμήν, harbour	λιμένος	λιμέσι
ὁ Ἕλλην, Greek	Ἕλληνος	Ἕλλησι
ὁ μήν, month	μηνός	μησί
ὁ αἰών, age	αἰῶνος	αἰῶσι
ὁ χειμών, winter, storm	χειμῶνος	χειμῶσι
ὁ ἡγεμών, leader	ἡγεμόνος	ἡγεμόσι
ἡ χιών, snow	χιόνος	—
ὁ δαίμων, divinity (voc. δαῖμον)	δαίμονος	δαίμοσι
ὁ δελφίς, dolphin	δελφῖνος	δελφῖσι
ὁ ἅλς, salt	ἁλός	ἁλσί
ὁ θήρ, wild beast	θηρός	θηρσί
ὁ θής, hired man	θητός	θησί
ἡ ῥίς, nose (cf. "*rhinoceros*")	ῥινός	ῥισί
ὁ ῥήτωρ, orator (voc. ῥῆτορ)	ῥήτορος	ῥήτορσι

NEUTERS

τὸ σῶμα, body; τὸ πέρας, end ; τὸ ἧπαρ, liver.

	Singular		
N., V., A.	σῶμα	πέρας	ἧπαρ
Gen.	σώματος	πέρατος	ἥπατος
Dat.	σώματι	πέρατι	ἥπατι
	Dual		
N., V., A.	σώματε	πέρατε	ἥπατε
Gen., Dat.	σωμάτοιν	περάτοιν	ἡπάτοιν
	Plural		
N., V., A.	σώματα	πέρατα	ἥπατα
Gen.	σωμάτων	περάτων	ἡπάτων
Dat.	σώμασι	πέρασι	ἥπασι

Like σῶμα decline τὸ πρᾶγμα, thing, affair ; (τὰ πράγματα = business).

Third Declension Adjectives. Adjectives of the third declension have usually two endings, one for masculine and feminine, the other for neuter. Most of these end in ης (neuter ες) and ων (neuter ον), as ἀληθής, true ; ψευδής, false ; πλήρης, full ; εὐδαίμων, happy ; πέπων, ripe ; σώφρων, prudent. They are thus declined:

	Singular			*Singular*	
	Masc. & Fem.	*Neuter.*		*Masc. & Fem.*	*Neuter.*
N.	ἀληθής	ἀληθές	*N.*	εὐδαίμων	εὔδαιμον
V.	ἀληθές		*V.*	εὔδαιμον	
A.	ἀληθῆ	ἀληθές	*A.*	εὐδαίμονα	εὔδαιμον
G.	ἀληθοῦς (for ἀληθέος)		*G.*	εὐδαίμονος	
D.	ἀληθεῖ (for ἀληθέϊ)		*D.*	εὐδαίμονι	
	Dual			*Dual*	
N., V., A.	ἀληθῆ		*N., V., A.*	εὐδαίμονε	
G., D.	ἀληθοῖν		*G., D.*	εὐδαιμόνοιν	
	Plural			*Plural*	
N. V.	ἀληθεῖς(έες)	ἀληθῆ(έα)	*N. V.*	εὐδαίμονες	εὐδαίμονα
A.	ἀληθεῖς(έας)	ἀληθῆ	*A.*	εὐδαίμονας	εὐδαίμονα
G.	ἀληθῶν		*G.*	εὐδαιμόνων	
D.	ἀληθέσι		*D.*	εὐδαίμοσι	

Some adjectives of the third declension, however, have only one termination, as: πένης, genitive πένητος, poor ; ἄπαις, ἄπαιδος, childless ; ἀγνώς, ἀγνῶτος, unknown ; ἅρπαξ, ἅρπαγος, rapacious ; φυγάς, φυγάδος, fugitive.

Verb "To Be": *εἰμί*, I am.

	Pres. Indicative	Imperf. Indicative
1. *Singular*	εἰμί, I am	ἦν or ἦ, I was
2. ,,	εἶ, thou art	ἦσθα
3. ,,	ἐστί(ν), he is	ἦν
2. *Dual*	ἐστόν, you two are	ἦτον, you two were
3. ,,	ἐστόν, they ,, ,,	ἤτην
1. *Plural*	ἐσμέν, we are	ἦμεν, we were
2. ,,	ἐστέ, ye are	ἦτε
3. ,,	εἰσί(ν), they are	ἦσαν

NOTES. 1. The first person dual of verbs is the same as the first person plural; it is not often used, and is therefore generally omitted in learning the verbs.

2. In present or primary tenses the second and third persons of the dual are alike, each ending in *ον*; but in past or historic tenses the third dual ends in *ην* (cf. *ἤτην* above).

3. When *ἐστί* and *εἰσί* are followed by a word beginning with a vowel, they are written *ἐστίν*, *εἰσίν*, for the sake of euphony or sound. The same applies to most words ending in *σι* (*e.g.*, all dative plurals of the third declension), and to all verbs of the third person singular ending in *ε*. Example: *οἱ ἵπποι χρήσιμοί εἰσιν ἐν τῷ πολέμῳ*, Horses are useful in war. This also holds good when any one of these words (*e.g.*, *ἐστί, εἰσί, πένησι*) is the last word in a sentence.

Regular Verb. λύω, I loose: Present and Future Indicative. The great majority of Greek verbs have the ending *ω* for the first person singular present indicative; the only other ending is *μι* (cf. *εἰμί*).

	Present	*Future*
1. *Singular*	λύω, I loose	λύσω, I shall loose
2. ,,	λύεις	λύσεις
3. ,,	λύει	λύσει
2. *Dual*	λύετον	λύσετον
3. ,,	λύετον	λύσετον
1. *Plural*	λύομεν	λύσομεν
2. ,,	λύετε	λύσετε
3. ,,	λύουσι(ν)	λύσουσι(ν)

SECTION II. SYNTAX

The ordinary rules of Syntax (such as the agreement of a verb with its subject in number and person, the agreement of an adjective with its noun in number, gender, and case) apply of course in Greek. These need not be recapitulated here.

RULE 1. When any part of *εἰμί*, am, connects the subject with a following noun or adjective the verb is called the *copula*, and the noun or adjective following is called the predicate. If in such sentences the predicate is a noun it will be in the same *case* as the subject; if it is an adjective, it will agree with the subject in *number*, *gender*, and *case*—*e.g.*, *Οἱ γέροντές εἰσι ῥήτορες*, The old men are orators; *Οἱ ἡγεμόνες ἦσαν σώφρονες*, The leaders were prudent.

RULE 2. In Greek a nominative in the *neuter plural* takes a *singular* verb—as, *Τὰ δῶρά ἐστι χρήσιμα*, The gifts are useful; *Τὰ ἄστρα ἦν φίλια*, The stars were friendly. (The Greeks regarded neuter plurals as forming a class, and as practically equalling a collective noun; hence the singular verb.)

RULE 3. Several subjects connected by ***and*** (*καί*) usually take a plural verb, and if the subjects are of different persons, the verb is in the first person rather than the second, and in the second rather than the third—as, *Ἐχθροὶ ἐγὼ καὶ σὺ ἐσμέν* = I and you are enemies (literally: "Hostile I and you, we are," the emphatic word coming first).

RULE 4. An adjective, with the article prefixed, is often used as a noun, the person or thing being understood—as, *ὁ σοφός* = the wise man; *οἱ δίκαιοι* = the just; *ἡ σοφή* = the wise woman; *τὰ ἄδικα* = unjust things, what is unjust (and so very often = injustice).

RULE 5. (Very important.) The article is not used with the predicate, only with the subject—as, *Ὄρνις ἦν τοῦ γέροντος δῶρον* = The bird was the gift of the old man (not *τὸ δῶρον*). In this way it is easy to distinguish the subject from the predicate, whatever the order of the words in the sentence. For example: *Διδάσκαλος τῆς κόρης ἦν ὁ ποιμήν* = The shepherd was the teacher of the girl. This rule will be found not to hold good in New Testament Greek, which is slightly different from Classical Greek.

EXERCISE IV.

[Words not found here have been given before]

and, *καί*
in, *ἐν* (governing dative)
basket, *τὸ κανοῦν*
egg, *τὸ ᾠόν*
I admire, *θαυμάζω*
soon, *ταχέως*
wicked, *κακός, ή, όν*
I dance, *χορεύω*
delight, *ἡ χαρά*
not, *οὐ* (*οὐκ* when next word begins with a vowel unaspirated; *οὐχ* when next word begins with an aspirated vowel—*i.e.*, a rough breathing)
I hope for, *ἐλπίζω* (takes accusative)
I say, *λέγω*
time, *ὁ χρόνος*
long, *μακρός, ά, όν*
but, *ἀλλά*
unkind, *ἄγριος, α, ον*
I pursue, *διώκω*
I fall, *πίπτω*
ancient, *παλαιός*
pleasant, *τερπνός, ή, ον*
I run, *τρέχω*
out of, from, *ἐκ* (governs genitive)
sad, *οἰκτρός, ά, όν*
Deity, *ὁ δαίμων*
that, *ὅτι* (conjunction)

Put into Greek: 1. There are a boy and a girl in the house (say, a boy and a girl are in the house). 2. The house is full of baskets, and in the baskets are eggs. 3. The eggs were the gift of the kind old man. 4. The boy admires the baskets: he loosens his (say ***the***) outer garment. 5. He will soon loosen a basket. 6. The girl is wicked, and dances ***with delight*** (simple dative without a preposition). 7. She hopes for the eggs: she says "The time is long." 8. But the deity is unkind: he pursues the boy and the girl. 9. The basket falls: the eggs are ancient, and the house is not pleasant. 10. The boy and the girl run out of the house, sad and wise.

KEY TO EXERCISE I.: Rhododendron, diagnosis, agkura [pronounced *ancura* (*Latin* ancora, anchor)], metamorphosis, catastrophe, pantomimos, Xerxes, Socrates, psalterion (psalter).

KEY TO EXERCISE II.: 1. *τοῦ νεανίου.* 2. *τοῖς ὀστοῖς.* 3. *τὸν ναύτην.* 4. *τοῖν στρατιώταιν.* 5. *τοῦ νόμου.* 6. *τῷ ζῴῳ.* 7. *οἱ ποταμοί.* 8. *τοῖς πολίταις.* 9. *τοῦ νεώ.* 10. *τὸ σῦκον.* 11. *τῆς νήσου.* 12. *αἱ κόραι.*

The next instalment of the ITALIAN **Course appears in Part 39 of the** SELF-EDUCATOR.

ART WORK IN METAL

Considerations of Art in the Treatment of Metals. Varieties of Metals. Embossing and Chasing. Casting, Spinning, and Turning. Engraving

By ALEXANDER FISHER

THE work of the hand is the first and last consideration in the expression of art in metal-work of any kind. When such is adequately given, the result is always sufficient to justify its existence. There is no art in any piece of work which does not possess the qualities obtained by hand work. To demonstrate this it is only necessary to try to think of a machine producing a work of art. Such a thing is inconceivable, inasmuch as all art is the expression of man's thoughts and feelings. The hand well trained alone can achieve that. One of the most lamentable things is to witness the painful effort of a worker to imitate the result obtained by the use of machinery. In the ordinary workshop this seems to be the great desideratum—the *sine qua non.* That it is necessary, then, to make art objects with the hands implies also that the design must be such as can best be expressed by hand work. Hence it follows that all designs should be made by one who not only knows the methods employed in the craft, but has also either practised it or is working in it. Not only so, but he must also have the keenest sympathy and enthusiasm for it. The designer and craftsman should be one and the same person, until he knows the craft so thoroughly that he can guide the work while being made by other hands than his own. For it is the artist who, by working continually in a chosen material, best understands its capabilities and what beauties can be wrested from it, as well as its limitations and suitable application. It is this true appreciation of the qualities of a particular metal which calls forth the highest design. To make the point clearer, attention is called to the frequent misapplication of metal-work, shown by the reproductions of woodwork, stone carving and plaster moulding, in wrought metal. This proceeds from a mistaken view of the use of metals, or the lack of either the knowledge of its capabilities or of invention and sympathy on the part of the designer. Not only is this true of the material, but also of the process, as in the case of wrought and cast work, where the difference should be felt and understood throughout the whole design.

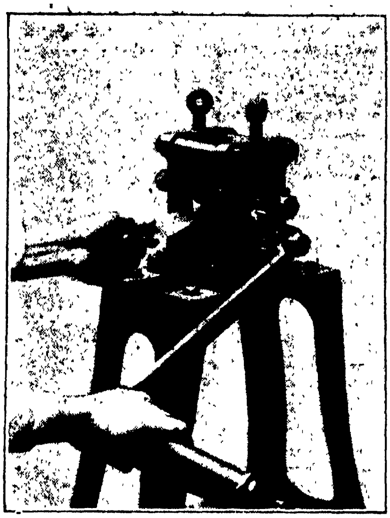
Study and Practice. The study and practice of the craft should be carried on at the same time as the study of design, either upon paper or in wax. They should not be pursued separately—that is, at different periods, one taken up for several years, and then the other—lest they both suffer. For by realising and embodying the idea or conception in metal, the mind gradually becomes accustomed to seeing clearly the design being made from start to finish in all its parts. In fact, so clearly is it perceived, that after a time the conception will present itself as vividly before the mind's eye as though it existed in actual metal before it. It is one of the most difficult mental problems to design or draw anything without having a clear presentiment or vision of the object. The usual method is to grope about over a piece of paper until something suggests itself from the number of lines sketched in, which, when it comes to be made, is found to look quite different from the drawing. Therefore it is best to advocate as a system of training the development of a constructive imagination, by the continual practice of both the design and the craft. They should never be regarded in the light of separate things. It is this unnatural divorce between craft and design which has been one of the chief causes of most of the deplorable work of the beginning and middle of the last century and much of the work of to-day. And one can only look forward to the time when they shall be united once more. Another deterrent in the production of art of a lofty aim is the lack of interest in fine art work of to-day displayed by the purchasing public. We are told that attention and devotion to ancient art is caused by the absence of really fine work to-day. At least, then, let us remove this cause.

Simplest Art is the Highest Art. Now, for reference only, the best study is to be found amongst the old work of the early periods of any civilisation. For specimens of goldsmithing and jewellery, those amongst the ancient Irish, Celtic, Greek, and what is left of Egyptian, Coptic and Scandinavian collections are to be sought; for wrought iron, British, German, Flemish, and French; for pewter, Dutch, English, and German; for silver, English, French, German, and Dutch; for enamels, French, German, and Italian. The earlier the date—in any civilisation of any piece of art work—the more generally does it imply the possession of those qualities which go to produce the finest art, such as simplicity, directness, purity of *motif*, restraint, virile strength, imagination and severity, together with the utmost perfection of handling and colour as seen in its best in the Irish jewellery. The later the period the more significant of redundance, femininity, extravagance, pretentiousness, poverty, and often impurity of *motif*—of conception, lack of breadth, simplicity, and the qualities possessed in earlier periods; such art work, so-called, has nothing but complete banality in all its parts, as seen at its worst in the French and Flemish Rococo, and periods under the influence of the Jesuit Bourbons. The decadent periods are usually the precursors of social and artistic revolution. followed by a reaction affecting severity and simplicity, as seen in the Empire style of France and the Adams style in England.

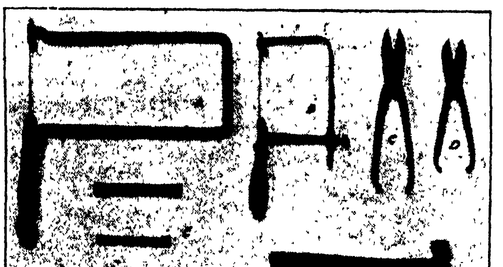
The True Value of Early Examples. The study of these styles or of any other should be for the sole purpose of understanding from them the expression of given forms and contours, contrasts and arrangements of line and mass. Not merely for the sake of the continuation and repetition of these styles, for no artist should be content to repeat the forms of expression used by men who have had their day and ceased to be. That is the wrong application of such study, and it is a sign of the times of how little is understood by the world of art when it is quite happy in seeing an endless purview of dead styles, thus causing on the part of artists and designers all effort of a sincere and original kind to be regarded as bad. This is prejudice and indifference, that kills or must be killed.



2. ROLLING METAL IN HAND MILL

This is a grotesque inversion of the idea held with regard to science and literature, and of what is considered advantageous and progressive for them. For in science the reverse holds good. In literature it would be considered unworthy for authors to imitate the idioms, phraseology and words, as much as repeating the ideas of writers in past times.

Study of Nature. Then, while studying ancient art, give more thought and reflection to Nature. Study her in all her varying moods, in her infinitely beautiful means of expression, from the smallest herb and flowering plant to the great trees, the movement expressed in their great limbs under the strain and stress of the storm, and the movement of the waters of the sea, and again the cloud masses. Then consider the lines expressive of calmness and strength in the steadfast hills; but study her most closely, intimately, in the forms and movements of animal life, and of the human figure. Do not study with the intention of copying, so much as to analyse what feeling or intention can be best expressed by adopting similar lines, masses, contours, whether of strength, beauty, grace, grandeur, gentleness; ascertain how she builds her forms and clothes them.



3. CUTTING TOOLS
A. Large frame and fret-saw *B*. Smaller ditto
C and *D*. Shears *E*. Chisels *F*. Hammer

Design. Referring in the most general terms to the broadest principles of design, it is necessary to bear in mind only that the straight line is the most beautiful of all lines, and that any deviation from it is less beautiful. Thus the curve, which is nearest the straight line, is the one that appeals to us most, as in early Egyptian, Greek, Celtic, and Saracenic art. So also in relief, flat surfaces are preferable to rounded, just as in the highest Greek form it is the flat planes and surfaces with the least curvature of parts which attain to that perfection of strength, beauty, and virility which one sees embodied there. Now, one of the great qualities in design is that described as "largeness of feeling." By analysis of most of those works which are generally conceded to be the finest, it will be noticed that this quality is maintained by simplicity, directness and singleness of conception, and scale in execution. It will be observed that there is a total absence of short curves, of violent light and shade, of prominent detail, and of confusion of parts, multiplicity of ideas, or complexity of aim. Detail, enrichment of surface, or ornament, elaboration of plan, were used so as to emphasise the beauty of the bare spaces, and in so doing these gave great preciousness to the enrichment. For it is apparent that straight lines, flat planes, simplicity of plan stand for and represent the great abstract quality *repose*, and therefore continuity, which implies infinity. In a similar way a curved line or surface repeated a great number of times suggests the same quality in a minor degree. If follows that all masses or curves, such as waves of the sea, or elaborations of whatever kind, carried on in a straight direction, repeated over a surface, represent the same idea. The trunk of a fir-tree, as straight as a column, or the slight curving growth of a chestnut, both indicate repose, because of the straightness of the direction of their growth. Contrast this with the gnarled oak. How eloquent it is of storms encountered and fought with! So that the broad principle is that continuity and simplicity, as represented by flatness of surface or straightness of direction, signify repose, infinity, and in the greatest work the sublime; and the contorted, twisted, intersecting, are emblematic of change. The smaller the curve and the more abrupt the angle of contour, the more rapid movement do they imply, and so on, in a descending scale.

Applying the Principles of Design. These general outlines the student must try to fill in for himself, and in doing so he will doubtless encounter many obstacles. But he will find ultimately that they are true. He will meet many things in nature, apart from the disputations of his fellows, which seem to say otherwise. It is important that the student should understand the means of conveying his intention. If he wish to attempt to walk along the high and lonely road towards the lofty planes of the beautiful, he will find it necessary to exercise great restraint even while exercising his imagination to the full. He will find that the beautiful implies the abiding sense of continuity. Life itself is transitory in the individual, but continuous in the race. Reflect upon this, for it is generally understood that variety, change, and contrast are the most beautiful qualities in art, whereas the contrary is proved to be the case in all the greatest monuments of antiquity and the present day. Then, if in the greatest, surely in the humblest work also. To take but two of the best known examples of different styles, the Parthenon and the interior of Westminster Abbey. In the former the whole composition is made up of straight lines and flat planes. The interior at Westminster is similar in this respect where the shafts are simply a mass of upright columns tied together, which in their sustained length, gently and slowly curving at the top into arches, give the almost extreme perfection of the expression of aspiration in repose.

4. DRILLING WITH A DRILL IN A STOCK

one of the axioms of design that suitability of purpose should govern a building, and consequently the governing facts in its decoration should be that it is in harmony with that purpose. So that edifices of a serious great motive and intention shall be decorated only with suitable appropriate ornaments, just as much as those of a lighter character. These remarks seem to be so obviously true, and therefore unnecessary, yet how often does one see our theatres dull and heavy, our drawing-rooms uninspiring, our churches full of unsuitable crudities displaying the utmost poverty of imagination and inappropriateness of form and colour. All there is consists of only such ornaments as can be stolen from some historical document concerning the art of a period and religion of a character totally different from the present one: in fact, everything save that which should be in such places of worship, praise and prayer. The subject of design as applied to the right use of curves, accent, harmony, and other qualities, and the appropriate treatment of materials, are discussed in the article on Design.

5. SOLDERING WITH BLOWPIPE AND FOOT BELLOWS

Metals. The number of known metals is considerable, there being forty-five in all. The majority of these are suitable in one form or another for art metal work, although very few are employed to any great extent.

The following comparisons show the different properties and characters of metals, which are here arranged in the order of their suitability to the purpose named above them.

MALLEABILITY. Gold, silver, copper, tin, lead, brass, zinc, platinum, iron, aluminium.

DUCTILITY. Platinum, silver, iron, copper, gold, brass, aluminium, zinc, tin, lead.

FUSIBILITY. Aluminium, tin, lead, zinc, brass, bronze, silver, copper, gold, iron, platinum.

ALLOYS. Copper alloyed with zinc gives brass, copper alloyed with tin gives bronze, silver alloyed with copper gives standard silver, gold alloyed with silver and copper gives the different carats of gold.

The junction of metals is attained by various means as follows:

In gold work the parts are joined by solder made of gold and silver or gold, silver, and copper melted together in proportions according to the carat of the gold.

In silver work a solder is also used made of silver and copper.

In copper work spelter made of copper and zinc, and a solder of copper and silver in much the

made of brass and silver is used.

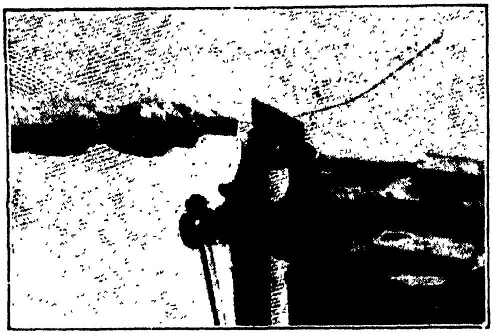
In iron work by welding and brazing.

In pewter, lead and tin and aluminium by fusion, and by pewter solder.

Nickel by silver solder.

All metals can be screwed, tied or riveted together.

That metals differ very widely in many respects, and that they are hard and soft and of different colour, is common knowledge. These differences can be modified considerably in most cases, which enables the worker to produce many things which otherwise would be impossible. Steel is the hardest metal. It is made from iron by introducing carbon into it while in a molten condition. But it can be made into a soft, pliable, or rigid metal according to the different properties of carbon and iron, or as brittle as glass by different applications of heat and methods of cooling afterwards. Possessing this remarkable quality it has become the most useful of all metals. Copper is the next most useful metal. Tin, lead, and zinc are largely used when mixed with other metals or applied to them. Gold and silver, besides being the most beautiful, are among the rarest metals found in the earth, and this prohibits them from being more generally employed. Other metals such as cadmium, vanadium,



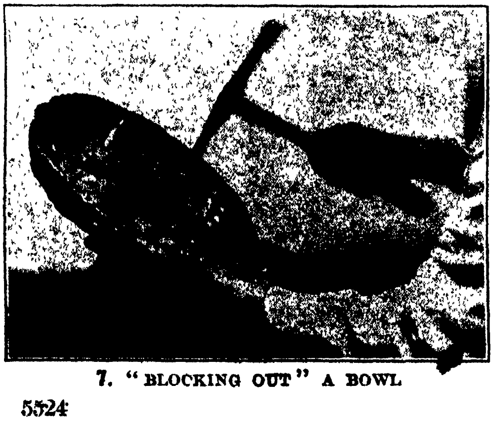
6. DRAWING WIRE

palladium, nickel, mercury are untarnishable metals of a silvery quality, which are usually applied to other metals for their reflective qualities, and for the protection of others the surfaces of which would otherwise rapidly deteriorate through chemical change caused by the atmosphere.

Processes in Metal-work. In the manipulation of all metals, the same processes are employed. The main difference in treatment lies in the size of work and the quality of handling. In the precious metals, gold, silver, and platinum, the handling should be kept fine and delicate according to the size and preciousness of the material—consequently the tools [1] are small and minute, whereas in making wrought iron they are, comparatively speaking, of enormous size. The hammers and punches, the drills and stocks, the stakes, mandrels and files are naturally regulated by the size of the work. So that here we shall describe the processes in detail common to all, in reading which it will be necessary for the student only to think of his material—either copper, iron, steel, gold or silver—to understand the matter rightly. All metals can now be procured in the sheet, bar, rod, or wire of almost any dimensions. Most of these are prepared by machinery to-day, and are as perfect as is necessary for all intents and purposes. The method employed in making sheet metals is as follows:

An ingot of the metal is cast measuring and weighing the proportionate amount to the sheet required. This is hammered into a flat piece, and after annealing it is placed between the steel rollers of the rolling or flatting mills [2], and then rolled, the size being gradually reduced by the tightening of the rollers to the gauge decided upon.

The gauge is a flat piece of steel about ⅛ in. thick, and having along both its edges a series of slots with a number marked below each for the purpose of quotations and reference, as seen in the illustration. There are two gauges in general use in this country, which causes great inconvenience owing to the frequent misunderstanding of the numbers quoted, so that it is highly necessary to state the kind of gauge which is referred to in an order. The names of these gauges are "Metal Gauge" and "Birmingham Wire Gauge."



7. "BLOCKING OUT" A BOWL

Sheet Metal. "Sheet" iron, copper, brass, gilding metal, are sold in sheets of varying dimensions, the most general size being about 4 ft. by 2 ft. The limit is according to the size of the rolling mills. To Mr. Sherard Cowper Coles we are indebted for an improvement in this limitation of size as regards copper inasmuch as by electrically depositing copper upon a cylinder a much greater size is reached and greater saving in the cost of production.

Annealing. Annealing is a word used to denote the process by which a metal is softened to its normal state after it becomes hard through bending, torsion, hammering, rolling, or through any process which involves the pressure of the particles of metal upon each other. Fine gold, fine silver, lead and tin do not become hard by hammering, but alloyed gold and silver, nevertheless, become hard enough to require annealing. Each metal requiring annealing is subject to the following treatment. It is first made hot, and kept hot equally all over, if possible, for a few minutes, and then allowed to cool gradually. In the case of steel it is necessary to arrange so that it cools very slowly, protecting it from the air while so doing. Other metals do not require so much care, but brass, low carat gold and standard silver should never be cooled rapidly by plunging into cold water, as may be done with copper.

Cutting. For all the soft metals—gold, silver, copper, tin, lead, nickel, iron and brass—if of an ordinary thickness a pair of steel shears or cutting pliers, or a metal-saw or fret-saw [3] is used for cutting. Shears can be bought either curved or straight, and suitable for cutting with the left hand or right. Metal-saws of almost any size can also be readily obtained. For cutting hard metals or thick metals, steel chisels are used. The angle at which these are sharpened is a very wide one, in order to keep the strength well down to its cutting edge, and they are tempered to a straw colour. Fret-sawing is done by first drilling holes in the various parts to be cut out, and then passing the saw through, fixing it firmly in the frame, and sawing in the usual manner, keeping the saw at right angles to the sheet of metal.

Tempering. Although tempering belongs particularly to one metal only, yet, as it has to do entirely with tools, we must describe it here. The first thing in making a steel tool is to soften the steel by heating it to a pale red and allowing it to cool very gradually; and then, when cold, to file it into the desired shape if a straight tool, such as a chisel, and if for a curved tool, by bending it while red hot. Then, to temper it, the steel is hardened by heating it again to a pale, red colour and plunging it into cold water. After this, one side is cleaned by emery cloth, and then a blowpipe flame is applied to within an inch or half an inch, as the case may be, until this part appears blue and the tip an orange colour. The moment this is reached the tool is plunged once more into cold water to arrest its further progress of softening. Now the tool is hard where it is straw colour, but not brittle, and tough where it is blue, yet not soft enough to bend while being struck. Swords are tempered in the same way.

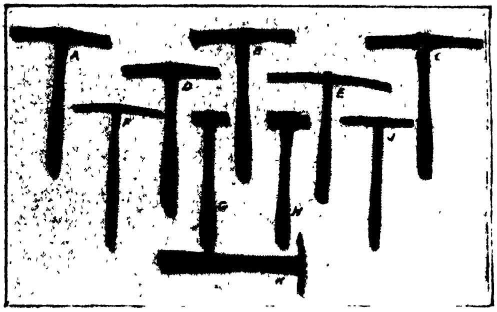
Drilling. In order to fix some parts of metal work together it frequently happens that they cannot be brazed, soldered, or welded together. In such cases the parts are held together by rivets or screws. Before any of these operations can be performed the separate pieces must be drilled [**4**]. Now, drilling is done either by means of a drill rotated by a bow, or fixed in a stock, or by a chuck placed in a lathe. A complete set of drills can be obtained from any silver or copper warehouse. The whole operation of drilling is a very simple one, as it entails merely the fixing of the drill securely into the breastplate if a bow is used, or into the stock or chuck, and causing it to revolve rapidly upon a given point. Drilling is aided by the addition of a little oil placed at the point of the drill for soft metals, and of soapy water for steel.

Soldering and Brazing. Soldering and brazing are identical in their process, which is performed as follows: The two surfaces are cleaned thoroughly either by filing or scraping or rubbing with emery paper, and when these parts are thoroughly clean the pieces of the metal are bound together with wire or held in position by clamps, or are fixed in fireclay or upon other stouter pieces of metal, and then the parts to be soldered or brazed are painted with borax dissolved in water, and the solder is cut into small pieces, which are placed along the boraxed parts. When this has been done the whole is subjected to a red heat produced by a gas blowpipe [**5**]. In the case of small work, such as jewellery, a mouth blowpipe is preferable; but for large work a large blowpipe with a foot bellows is used.

9. PLANISHING A SILVER BOWL ON A STEEL-FACED STAKE

Wire-drawing. The process of wire-drawing [**6**] is performed by means of pulling the wire through a regular series of holes pierced in a hard steel-plate by tongs. This plate is called a *draw-plate* and the tongs *draw-tongs*. As the metal wire becomes very hard and brittle in the process of drawing, it is necessary to anneal it repeatedly and to use a little oil when passing it through the plate.

Hammering. The methods employed are practically the same as have existed from antiquity. They consist of first raising the metal from the back and then finishing it from the front. The softer metals only are used for the purpose of making objects such as cups, tazzas, bowls, vases and other articles of a similar form. The tools employed are those of the most primitive yet effectual character. They are hammers of various kinds [**8**], as shown in the illustration, the size of which is naturally governed by the size of the object. The long-headed hammers are used for raising and drawing in the metal, and the short, flat ones for finishing and planishing, as it is called, with stakes, mandrels, angle wires, tee-pieces, etc.



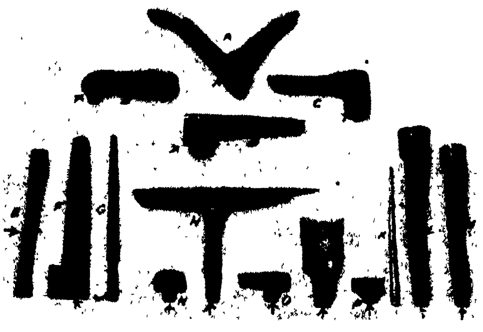
8. HAMMERS FOR ART METAL WORKERS

G and *H* are planishing hammers; the remainder are for raising, "blocking out" and "drawing in"

The detailed process of raising and drawing of a silver bowl, such as the one in the illustration, is as follows:

Cut your piece of metal from a flat sheet No. 18 metal gauge. Measure the edge of the design from the centre of the base of the bowl to its edge, and allow a quarter of an inch for cutting and filing this true at the end of the operation. Then strike out on your silver a circle, with this as the radius, with a pair of steel dividers. When this is done cut it out with a pair of shears, and then place it upon a block of wood, similar to that used by a butcher; with a hammer made of buffalo horn strike it in a series of circles, with regular blows, holding the silver at an angle of about 25° to the block [**7**]. It is better if the block is slightly concave. Then anneal it. After it is cool, take the silver again, and by holding at an angle of 30°, repeat the process of hammering again; and so on, until it is raised into a shallow saucer. After it has been annealed and pickled, turn it over on to a stake of this shape, and strike it on the outside in a similar way [**9**], turning it slowly with the left hand as you hammer it.

The important thing to aim at is to direct each blow upon the part which is immediately in contact with the stake; each blow should produce a clear, sharp, metallic ring, and in this way the silver is stretched into the shape of the stake, which should, of course, be the shape of the cup at some part or another. From this it will be gathered that the



10. VARIETIES OF STAKES

A to *D*. Side stakes *E*. Canister stake *F*. Side stake *G*. Ring mandrel *H*. Beck iron *J*. Square-faced stake *K*. Ringed stake *L* and *M*. Canister stakes *N* to *P*. Heads for vice crank stakes required [10] are considerable in number, as it is obvious that each section of a given bowl should have its corresponding stake upon which the metal can be beaten into shape. When each complete course of hammering has taken place, the silver must be annealed and carefully cleaned. Then the operation of planishing completes the process. It is exactly the same as other hammering, except that it is performed by a short, flat-headed hammer, with a polished face. From its lowest part up to the rim the cup is slowly and thoroughly beaten with it until all other hammer marks are erased, and a regular faceting of the surface has been given to it. If it is perfectly done it should not require to be polished afterwards.

The above description will apply equally to the raising of any forms in any metals. Such metals as nickel and steel are naturally unsuitable for this work, as they are too hard.

11. METAL REPOUSSE SHRINE OF FOURTEENTH CENTURY WORKMANSHIP

Embossing, Repousse, Chasing. *Embossing* and *chasing* are terms applied to the methods of enriching an object in metals by relief, produced through beating it with punches which are struck by a hammer first from the back to raise parts and then from the front to sink others, and to finish the raised parts.

The simplest form of embossing is done upon a lead block, and for large, simple decorative wrought work it is quite sufficient. But the finer kinds of "repoussé" or "embossed" work [11] are done upon a composition of pitch, plaster and oil. The great drawback to this composition is the amount of time taken up in fixing the plate to the pitch, and taking it off and re-cleaning it. But there is no other composition half so good. The tools are made from square steel rods, which are cut into lengths of 6 in. or 7 in. each, shaped at the ends according to the required line or relief. They are entirely dependent upon this and the size of the curves, or parts in relief for their shape. They are tempered straw colour at their ends. The number of tools of this kind that a chaser possesses is, as a rule, very great. As many as 150 are often required if the chaser does a great variety of work. Then he has small riffles, which are pieces of steel having at each end a little curved or flat tong of a file, either coarsely or finely grained. It is a method of work which is capable of giving great beauty and richness to metal surfaces.

After the design has been drawn or transferred to the back of a sheet of metal it is traced—that is, gone over with a flat blunt chisel-shaped tool, which is struck regularly with a chaser's hammer while the tool moves slowly along the line. The parts which are to be raised are forced up in the same manner with larger, rounder faced tools of the same convexity as that part of the relief. This is repeated, using different suitable tools until the whole presents from the other side a roughly-embossed relief. After it has been removed from the pitch and cleaned, the back now requires to be filled with pitch and placed upon a pitch block, or bowl, as the case may be. And the surface is improved by the gradual smoothing and finishing with punches. Here parts are made sharper and clearer, and there more soft and delicate. In 12 and 13 are illustrated some early specimens of art metal produced by these processes.

Casting. The central principle of casting, of which an example is shown in 15, consists in making a mould and then pouring metal into it, or depositing by electricity. There are three ways of doing this, properly speaking—by sand, by "lost wax" ("cire perdu" or "cera perduta") or by electrolytic deposition.

The first is carried out by making a piece mould in wet sand from a plaster of wax model, and then the parts are firmly placed together in an iron box. The whole sand mould is dried, and the metal, while in a liquid state, is poured into it.

The *cire perdu, cera perduta,* or lost wax method, differs widely from the above. It is briefly performed as follows: After a plaster mould has been taken of the original model in beeswax, with the least amount of rape oil added to soften it, together with a little colouring matter, it is pressed into it, thus giving a model in pure wax. A core is inserted of brickdust and plaster, and on the outside a very solid mass of the same composition is put. Upon the model rods of wax are set on its prominent parts, passing up through the outer mould. After the whole mass has been subjected to a continuous regular heat for some time, during which the mould has been drying and the wax running out, the metal is poured into the main duct, from which it is carried through the other ducts on to the mould. By this means the whole thing is practically reproduced as in the original, as the metal now occupies the exact position of the wax, as though the wax had been transformed to metal. Further details of casting will be found in the section on Sculpture.

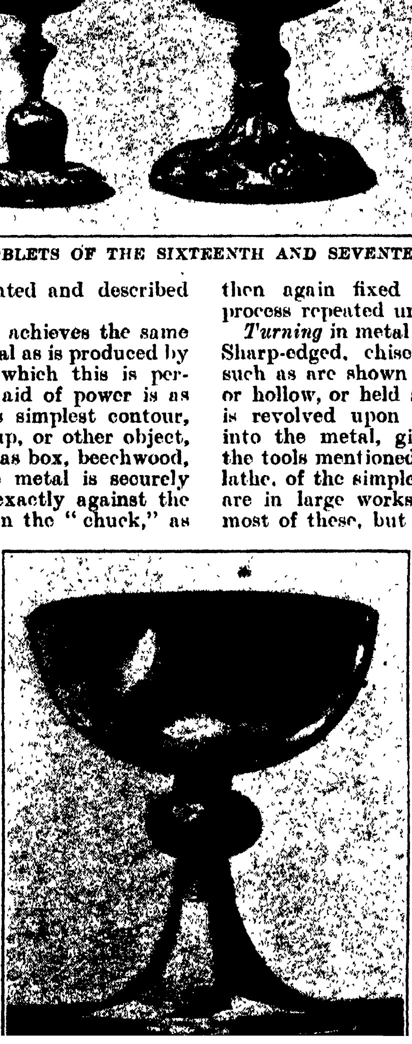
Electric deposition is simply the deposition of copper or silver or gold into a gutta-percha or vulcanite mould, which is immersed in a bath of solution of sulphate of copper.

Spinning and Turning. Two modern methods, which are closely allied in their processes, are spinning and turning. They are mechanical methods, and are to be decried for many reasons, the most important of which is given at the beginning of the introduction. Yet it is necessary and advantageous to know how to accomplish a piece of true spinning and turning—for this reason, that there are frequently parts of an object in metal which have to be exactly fitting and corresponding to other parts in their construction, so that they cannot be so well or quickly done by any other means. Examples of the method of making

12. CUPS AND GOBLETS OF THE SIXTEENTH AND SEVENTEENTH CENTURIES

various objects will be illustrated and described in detail.

Spinning is a method which achieves the same result upon a piece of sheet metal as is produced by hammering. The manner in which this is performed by hand without the aid of power is as follows. First a shape, in its simplest contour, resembling that of the bowl, cup, or other object, is turned in a hard wood, such as box, beechwood, or mahogany. Upon this the metal is securely fixed, with its centre placed exactly against the back-centre of the lathe. Then the "chuck," as the wood shape is termed, is revolved, carrying with it the metal disc, and while revolving, the end of the long steel burnisher is pressed with considerable force against the chuck, the handle forced underneath the armpit, and the middle of the tool supported on the slide rest, so that the whole weight of the body can be used. This is aided either by the lathe being placed as near to a wall as would allow a man to put his back against, or a leather strap fastened to the lathe, which goes round his back, thus enabling him to push with great force the burnisher upon the metal, and so press it down upon the wooden shape. When the first shape has been reached, the metal is annealed and the wood is taken a further stage. Then the metal is turned a little more into the shape desired. The metal is then again fixed against the wood, and the process repeated until the object is finished.



13. EARLY ICELANDIC CHALICE OF SILVER PARCEL-GILT

Turning in metal is similar to any other turning. Sharp-edged, chisel-shaped tools are employed, such as are shown in **14**, while the metal, solid, or hollow, or held securely upon a wooden shape, is revolved upon the chuck. These tools cut into the metal, giving the required form. All the tools mentioned are, with the exception of the lathe, of the simplest possible description. There are in large workshops innumerable varieties of most of these, but they are generally such as are for large work and thick metal. They are time-saving machines where a number of men are employed, but are too costly for small workshops. The lathe, however, is almost a necessity, for with it many things can be done with ease which otherwise would waste the time of the artist craftsman.

The most suitable metals for spinning are gold, copper, silver, brass, and pewter; and for turning, brass, silver, and copper.

Acids. The acids which are used in metal-work and enamelling are sulphuric, nitric, hydrochloric, muriatic, hydrofluoric. They are employed for different purposes.

Sulphuric acid, mixed with water in the proportion of 1 part of acid to 20 parts of water, is the most useful for cleaning copper, silver, and gold, both before and after soldering. It cleans the metal in both cases, so that in the first place the solder runs smoothly, and afterwards it dissolves the borax. It is most advantageously used when heated to boiling point. The first operation in cleaning metal—that is, of leaving the metal in cold sulphuric acid and water—is called *pickling;* the second is generally referred to as *boiling out.*

Nitric acid, or *aqua fortis,* is used in the process called *dipping* copper or brass objects. That is, after a piece of copper or brass has been cleaned in *pickle,* otherwise sulphuric acid and water, it is held on a copper wire and dipped into a bath of aqua fortis, which is commercial nitric acid. For most dipping it is sufficient to use it below the pure state. Dipping is a term given to the process of sudden immersion and removal from the bath, by which a brilliant surface is given to the metal.

Hydrochloric, or aqueous sulphuric acid, is sometimes preferred by goldsmiths for cleaning gold and giving it a yellow colour, as it dissolves the alloy of copper. It is also occasionally used in cleaning copper, particularly when it is to be electro-gilded afterwards. The most general use to which it is put is in what is termed "soft soldering," that is, soldering with pewter solder. For this purpose the acid—or, as it is popularly called, *spirits of salt*—is killed by dropping particles of zinc into the acid, which is then put upon the parts to be soldered.

Aqua regia is a mixture of hydrochloric and nitric acid.

Muriatic acid is largely used in colouring gold articles.

Hydrofluoric acid attacks any kind of enamel or glass. It decomposes the silicates, which are the chief parts of glass. For the purpose of removing any portion of the surface of enamel, or for dissolving it entirely, this acid is the only one which can be employed. It is a very dangerous acid, and should be used with great care.

14. VARIOUS TOOLS
A to *E*. Tools for spinning *F* to *K*. Turning tools
L to *Q*. Screw-cutting tools *R*. Hack-saw

Polishing. If a surface of metal be rough through filing, the method of smoothing and polishing by hand is as follows. Take rough emery cloth and rub it all over until the file marks are removed; then use a finer emery cloth, in grades, until the finest is used. After this, take powdered pumice and oil, and with a stiff brush scrub it all over until a smooth surface is obtained. Then, with a soft woollen or worsted material and rottenstone mixed with oil, rub it again, when a dull polish will be given. Then, with a chamois leather and rouge polish it brightly. To polish in a lathe the same means are employed, save that mops, buffs, and laps are employed, fixed on the chuck.

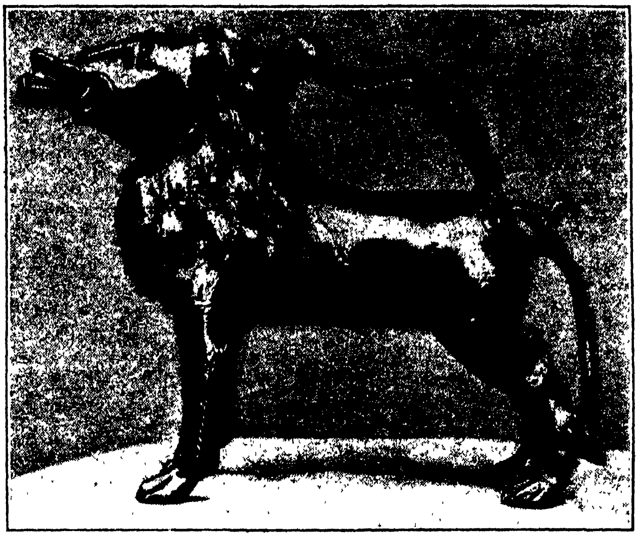
Burnishing. By the use of a burnisher, either of steel, hematite, or agate, a still higher degree of polish can be obtained. Burnishers are made in all kinds of shapes to meet the requirements of the article to be burnished, and are used with a little soapy water. Continual light rubbing in various directions, while the object is held rigidly in a piece of fine tissue paper or chamois leather, produces a brilliant burnished surface.

Engraving. Properly speaking, this art is the oldest of all known methods of enriching metallic surfaces, as it is found in the earliest periods of the Bronze Age. For with a pointed instrument made of hard stone, such as a flint, it was found that a line could be scratched or cut in the metal. From this to the exquisitely engraved work of the Irish Celtic jewellery [**16**], and later of the fifteenth and sixteenth centuries, is, after all, a small step in result, yet it took ages in its achievement. The great obstacle in the development was the tardiness with which the discovery of steel was made. From the smelting of bronze to that of iron whole periods of the struggle for existence and for man's development passed away. Then, from the forging of iron to its conversion into steel, even in the most primitive form, necessitated long stretches of time in human advancement. The conquest of material and the subjugation of natural forces to man's will is a slow one, even when, as now, the greatest talent is devoted exclusively to that particular direction and aim. When the mind has been taught to rely upon itself for aid, and has been slowly but laboriously disencumbered of all the wild phantasmagoria inherent to the savage man-child, we come to the development when we can go out and obtain in the simplest fashion the steel graver of to-day.

Engraving Tools. Yet no discovery which simplifies things for the many is entirely without its drawbacks for the individual. The tools which, as in this case, are to be used directly by the hand must be such as will suit the hand of the operator using them. Therefore, when you have purchased them, the first thing you will find is that it is necessary to shorten the tools and cut the handle to the shape of your own particular hand. Many engravers find it advantageous to employ a long handle with a small, roundish head that will fit into the palm of the hand. Others prefer a short handle. Again, most of the tools, gravers, spitzsticklers, scorpers, etc., are cut at a too oblique angle for metal engraving—which causes the edge to be liable to break. The first thing to do, then, is to make the tool and handle fit your own hands. If you find it advantageous to shorten the tool, you must first of all soften the steel by heating it to a pale red, and then allow it to cool, after which you file it down, smooth it up with emery cloth, and then temper it as already described. Then sharpen upon an oilstone (fine Turkey stone is the best, and should always be kept clean and covered, to protect it from dust). In sharpening, take care not to cut the stone into grooves, or you will spoil it, and it will be of no further use.

The next thing to do is to fasten your plate, or cup, or whatever the object is, firmly upon a stick or block, as the case may be. For small work, such as a ring or pendant, place some melted resin on the end of a round stick, then warm the resin, and fasten the article to it. If, on the other hand, the object is a cup or large object, fill it with pitch and put it upon a pitch block as though for chasing. Then hold the arm rigidly, the thumb pressed firmly against the plate, and by pressing with the back of the hand forward and rotating the stick —or block—in a contrary direction as the design may require, the line will be cut. It is obvious that the tool must cut along laterally, and not in a downward direction, and it is by constant practice that this is acquired. The line is then cut deeper and broader, according to the boldness or delicacy desired.

For different effects the line is cut hollow, curved, V-shaped, or flat; for each of these the tool must be accurately made. It is a good thing to practise cutting all sorts of curves by different gravers and comparing the result, and then examining the best work through the knowledge thus obtained. For damascening, niello, and enamelling the same process is employed, with this sole difference, that the parts in which the gold or silver is to be let in the steel, as in damascening —or the sulphide of silver and lead to be melted in as in niello, or the enamel fused in the spaces cut out as in champlevé enamelling—the parts are cut much deeper than is the case for engraving simply. These latter processes will be described under their proper headings.



15. FLEMISH CAST BRASS EWER OF FOURTEENTH CENTURY

Engraving, on a small scale, either for gold, silver, copper, brass or iron is invariably done by the unaided pressure of the hand holding the graver. But for large work, such as memorial brasses for inscriptions, hammer and chisels are used. In this case the chisel is held in the left hand and struck with a chaser's hammer, much in the same way that repoussé tools are used, save that instead of beating the chisel while holding it at right angles to the surface of the metal as in repoussé, the chisel is held obliquely at about an angle of 45°. Little pieces are flaked off at about every third blow. Another method is properly described as etching, but it is often erroneously referred to as engraving by acid, and does not come into this category.

Die-sinking. Die-sinking is very intimately connected with engraving and carving. Carving is very rarely done, as metal does not yield to such treatment as well as to other methods described. But die-sinking is one of the most common of the operations to which metals are subject, and it is at the same time a distinct method, so that it requires adequate description. It is generally used in striking medals, coins, badges, or other articles in bronze, copper, silver, or gold, in which fine detail is required, and where the work is to be reproduced many times. A block of steel is used. It measures across the face a little more than the piece to be struck, and deep according to the size of this face, in order to withstand enormous pressure. Then, upon this prepared surface — that is, a perfectly true smooth surface—a mould is carved with steel chisels, gravers and riffles. A very careful model is made in plaster, and is then copied in the steel. It is a work which requires the greatest knowledge of the use of tools, as well as the most careful concentrated effort. A really fine knowledge of form and modelling is absolutely necessary. While the process of carving or die-sinking is in progress, wax impressions must be repeatedly taken in order to see how the work is going on. When it is complete, the surface must be tempered, and upon this being satisfactorily accomplished, the die is placed in a press, or underneath a heavy bolt, raised by a pulley and dropped, and the metal disc is struck. If the die is not properly annealed and tempered it will crack in this process. The metal disc also must be of the softest description and carefully annealed.

16. SILVER-GILT FILIGREE BUCKLE

Niello. Niello is an inlay of an amalgam of silver, lead, and copper, in the proportion of 12 parts of silver, two parts of copper, and one of lead, to which is added powdered sulphur in excess, while the mixture is in a fluid state in the crucible. This is pulverised when cold, and into the engraved parts of silver, gold or copper the powder is placed. But before doing this it is necessary to apply a little borax, and run it well on to the engraved parts, then the powdered amalgam is shaken all over the metal thickly and baked. After it is withdrawn and the defective parts mended, the whole is rubbed down with files and emery, and finally polished. It was at one time very largely used upon silver. A considerable amount is still done in Italy and Spain, but it has never been very much in request in England, probably owing to its absence of colour. The great examples are the altar frontals at Pistoria Cathedral and at the baptistery at Florence.

NOW AND FOREVER

Man Must Live Not for Now Only, but for Ever. A Fair Field and No Favour for Truth. Factors that Mould Society. The End of the State is Liberty for All

By Dr. C. W. SALEEBY

NATURE'S rule has always been "a fair field and no favour." Let the strongest and the fleetest win; whatever can survive may survive. But there is to be no shrinking from the contest; "natural selection is the dread ordeal which must be passed by every aspirant to existence." It is a law at once benign and terrible. The conditions must be the same in the battle of ideas. We must have a fair field and no favour. "Established" ideas, whether they be those of established Churches or Royal Academies, or Royal Societies, or the House of Lords, must come out into the open. If they are right they will win; and if they are lies, is not an established lie the worst of lies?

No Quarter for a Lie. This transference of the plane of struggle has a definite interest for the moralist. Though natural selection acting on the physical plane is benign in the last resort, yet it is terrible. Nature has no mercy on the unfit, and they die of murder, cannibalism, or starvation. But when the battle is transferred to the plane of ideas, this terrible aspect of the defeat which is always implied in victory is found to vanish completely. Suffering now accrues only to those who will not bend the knee to the truth. As for the beaten and exposed idea, it is not a sentient thing, but an abstraction, and it cannot suffer. On the plane of the physical there is good cause for some mercy to the defeated, even though their defeat is a necessary condition of progress. But on the spiritual plane there is no need for mercy at all. It is a misplaced tenderness, then, that would deal gently with lies. Let them be gibbeted as such; it does not "hurt" them, and it is in our highest interests. Let the fight be fought without mercy and without quarter. Let our motto be "No quarter for lies." This is no place for mercy. Lightly to estimate a lie is lightly to estimate the truth which it belies. But in this great struggle to which we are all called we must distinguish between the idea and its personal champions.

Error is Not Sin. No better illustration of the principle which we are trying to express can be found than in the well-known saying that "God hates sin but loves the sinner." There is to be no quarter for lies, but we are not to confound the lie with him who mistook it for the truth. We are doubtless in the same case ourselves as to many of our beliefs. It is not immoral morally to hold an immoral doctrine. At one time, when first there began that great battle of ideas which is the great fact of our time, it was held that the holding of a false belief was the act of an evil will: "Error is sin." "Bishop Martensen once declared that the only explanation of the defection of men like Kant, Jacobi, Schiller and Goethe, from the doctrine of the Church was that in the depths of their hearts they entertained an antipathy towards the holiness of the Godhead." On the contrary, we must combine with our warcry, "No quarter for lies," a recognition of the imperfection of the human mind and the humility which knows that even a Newton is only a child picking up pebbles on the shore of the ocean of unplumbed and illimitable truth.

The Search for Truth. Says Herbert Spencer in his great discussion of the reconciliation between religion and science: "In proportion as we love truth more and victory less, we shall become anxious to know what it is which leads our opponents to think as they do. We shall begin to suspect that the pertinacity of belief exhibited by them must result from a perception of something we have not perceived. And we shall aim to supplement the portion of truth we have found with the portion found by them."

If the reader asks whether we are straying far from sociology let it be answered that, on the contrary, we are at the very heart of our subject, for we have been endeavouring to discuss, upon the basis provided by the solid ground of Nature, those great principles which underlie all the possibilities of social progress.

The reader remembers the great quotation from Wordsworth, of course:

> "To the solid ground
> Of Nature trusts the mind which builds for aye."

If we use the great names conservative and liberal in senses worthy of them, so that they are really capable of analogy with heredity and variation, we may distinguish in society certain forces or institutions or individuals who stand for perpetuation, and others who stand for innovation. In general terms, then, we find that the most vigorous and active years of life display the tendency to liberalism, or variation, whilst old-age displays a tendency to conservatism, or to the perpetuation of what is already established.

The Conservatism of Old Age. This conservatism of old age is, needless to say, an extremely valuable complement—the old man would say antidote—to liberalism, the openness of mind, the readiness to accept the new, which is more characteristic of youth. It is worth noting that the conservatism of old age, which in a man's second childhood is extremely marked, is a return of the marked conservatism of childhood itself. There is no more conservative society than that of a boys' school. It may also be noted that in primitive societies, corresponding to the childhood of the race, conservatism is the rule—the laws of custom being laws of iron. Whilst saying these things we must not underrate the value of the reasonable conservatism of elderly men and women. These constitute by far the most valuable conservative forces of society, for they have had experience, which means that they have gone some way at any rate towards proving all things. On the other hand, government by grey-beards without its complement, the influence of youth, has always proved itself disastrous. In an ideal society, where all men are philosophers, youth and age will perfectly understand their respective tendencies and will perfectly understand that the best results follow, not when youth has its way, nor yet when age has its way, but when the tendencies of the two are combined.

The Conservatism of Women. Turning from individuals to the sexes, we must recognise that, on the whole, men constitute the liberal sex and women the conservative sex. Women prefer to make the best of existing circumstances and customs and to insist upon their good points, whilst, on the whole, the male tendency is in the other direction. As a sex, women are certainly less apt than men to accept the new for the sake of its novelty. The Athenians who were constantly desiring some new thing were not Athenian women, but Athenian men. Now, just as Nature with her amazing wisdom makes provision for a due supply both of conservatism and liberalism by means of the respective tendencies of youth and old age, so also does she make this provision by means of the respective tendencies of the two sexes. Very conspicuous amongst the consequences of the conservatism of women is their adherence in all places and ages to Established religion. This is a demonstrable truth of history of the most marked and salient kind, and it is by means of their support of Established religion that women at all times have most potently exercised their conservative influence upon society.

The Chief Conservative Force in Society. For now we must recognise the most important sociological truth—that the chief conservative force in all societies is the Established religion. If we ignore the relative values and qualities of different religions and simply look upon Established religion—whether Fetichism or Buddhism does not now concern us—as a constant social fact, then we may fairly argue that the most important and characteristic function of ecclesiastical institutions in general is the conservative function. In all Established religions we find the uniform conservative characters. "Every religion insists upon the peculiar authenticity of its origin, and the essential finality of its pronouncements. The official exponents of every religion have everything to gain and nothing to lose by conservatism. Every religion inclines to teach that it has already proved all things, and that nothing remains save to hold fast to that which it has proved to be good and true. Every religion goes even further. It invents a special name for variation, and, on the assumption that, perfection having been already attained, all variation in belief and practice must be bad, it calls such variation heresy, and condemns it outright. Whenever it has the power it suppresses the heretic, if possible, with such accompaniments as will serve 'pour encourager les autres.'" *But the founder of every religion was a heretic.*

Established Religion of Society. If we attempt to look upon the conservatism of ecclesiastical institutions in a really judicial way we shall recognise that, despite its evident evils, it has served great purposes. In various times and places it has made for the strength and persistence of societies. It has helped to give them that internal unity which has made them strong against external foes. Much, indeed, might be said, if space availed, in proof of the proposition that the conservatism of Established religion has been of value in the progress of society. In the present writer's judgment there is one most conspicuous instance of this. It is furnished by the Christian Church in its patronage and support of the fundamental social institution of marriage. Here is a case where "that which is good" had already been proved good by the action of natural selection through many past ages. The Christian Church, in due accordance with the conservative character which is common to all religious systems, high or low, has persistently held fast to that which is good in the instance we are considering. When the time comes to estimate the services and the disservices of ecclesiastical institutions in general, recognition will have to be paid to the incalculable service rendered by the Roman Catholic Church during many centuries by its patronage of marriage; and the true man of science will not hesitate to pay his tribute even to ecclesiastical conservatism acting upon intellectual progress.

The Greatest Battle in History. For what, when we come to think in terms of principles, is the explanation of the age-long conflict between religion and science—a conflict which has always been of great sociological interest, and which, in the present day, is perhaps the most salient of all sociological facts? Is not the answer that, while religion is essentially conservative, science is essentially liberal?

We have already contemplated the organic world and its history as the theatre of an age-long, bloody, and yet ultimately benign struggle between the representatives of the tendency to persist and the tendency to change. We have already seen cause to think that human society is also the theatre of one and the same conflict, and further, that, as in the older case, the issue of the conflict will determine the future. Now it is in the conflict between Established religion and science that we see the old struggle still waged, though now in its highest and most important form. Man is essentially a spirit, and not a muscular machine. The essential struggles of man, the essential struggles of human society, are therefore no longer mechanical or muscular but spiritual, and it is in the struggle between Conservative Religion and Liberal Science that we see the battle of ideas fought on a scale and with consequences which constitute it the Armageddon—the supreme battle—of all history.

On which side would you have us range ourselves? the reader may ask. And to this there is a sure answer. If our analogies mean anything, if it was worth while to study heredity and variation in sub-human life, if all that we have been saying hitherto is not nonsense, the answer is that we are to range ourselves on neither side. Not because we do not care, but because we are beginning to get a perception of a whole truth, and can no longer shut our eyes and fight to the death for half truths. Heredity and variation are both necessary. Conservatism and liberalism are both necessary. Each without the other would mean disaster; each is a half truth.

Half Truth is Not Truth. In all time the battle has been fought between those on either side who, so to speak, believed that the half-truth was the whole-truth, and the upshot has been that the strong and wholly true thing has ever tended to emerge, and having emerged, to persist. Now there are those to-day, as in the past, who still rank definitely on the one side or the other. There are living ecclesiastics who say that they cannot let go one word of the Bible or else the whole must go. Of all conceivable forms of "unbelief" this is surely the most horrible. On the other side are those who would utterly abolish all Established religion and all religious beliefs. For such men, whether of the one party or the other, their perception of even their half-truth is so imperfect that nothing better can happen than their mutual destruction, the speedier the better. The bigoted ecclesiastic and the bigoted atheist still survive, and though they serve no great or good purpose, at least they may show us how, in the transmutation of the struggle for life from the merely physical to the psychical, the old metaphor of battle becomes no longer applicable. It is applicable to such as these, who, indeed, would cheerfully kill each other if they could. But we shall now see that in the higher struggle of to-day there is a new and beautiful metaphor which will replace the old.

Many Roads Lead to Truth. The true metaphor to-day, we think, must be derived not from the idea of battle, but from the idea of marriage and parentage. Battle was no metaphor, but the literal truth, so long as the struggle for existence was physical and resulted in the survival of the physical. Now that the struggle for existence has been transferred to the plane of the psychical, the idea of battle is applicable only to contests between absolute truth and absolute falsehood. But reasonable persons nowadays, influenced by the great idea of toleration, are coming to see that, whatever their opinions, nothing more than approximation to the truth is possible for finite man, and to truth the many-sided there are many approaches. The wise and fruitful view, then, alike for the conservative-minded, who see the valuable aspects of established things, including religion, and for the liberal-minded, who see the need of new things and who can scarcely keep their hands off what Höffding calls "the dead values" which religions tend to drag about with them, is that nobly expressed by Spencer in a passage which we have already quoted. It is the idea of union consummated between the truth partially perceived by one type of mind and yet another truth partially perceived by another, the fruit of such a union being a yet higher and deeper truth that neither side could formerly perceive. Thus, at last, we may be "led into all truth," and so attain the goal of the mind of man.

The Factors of Progress. And this, to our mind, expresses the highest worth of the principle of toleration. It is not merely that the practice of toleration removes from society its most appalling evils, such as religious persecution and the wars of religion, but it makes, as no other condition can make, for our advancement towards the goal of truth. There is scarcely a more terrible revelation than that which the mind attains when it asks what point humanity would now have reached if throughout merely the brief period of recorded history the characteristic conservatism of savagery had been completely complemented by the practice of toleration. What is it that has conditioned the progress which even recorded history demonstrates?

Certain things may be excluded. There has been no advance of the slightest moment in the physique or the bodily characters of man. Secondly, there has been no advance, or no demonstrable advance, in the inherent psychical qualities of man. The baby born in the twentieth century after Christ would, on the average, be neither above nor below the average if it could be transferred to a nursery of three thousand years ago. The achievements of the Greek mind have yet to be surpassed; the present age, with its manifold advantages, has not yet beaten the Greek record. Indeed, it is beyond dispute that all mere biological or physiological reasons to explain the recorded progress of the historic epoch are lacking.

Man and His Social Conditions. There remains only the supreme fact that in each generation some psychical conquest is recorded—not merely some intellectual conquest but some psychical conquest, whether Newton's "Principia" or "Hamlet" or the record of a noble life—which becomes a permanent possession of the human mind and the human race. For thousands of past years the inherent characters of man, necessary for the winning of such victories, have been present. It is to the social conditions which have surrounded him that we must turn for an explanation of the fact that we, in this age, have not already reached such psychical heights as we may hope for our descendants of the year 5,000. Organic or physical evolution is an exceedingly slow affair. Hundreds of thousands of years are necessary for the contemplation of the history of definitely recognisable man. The period in which progress has been made from barbarism to civilisation is a mere nothing in the whole history of man, and the only explanation of its brevity and the magnitude of its achievements therein is to be found in the development of those conditions which have enabled individuals to make psychical conquests and to endow with them not their own time alone, but all future generations.

The New Must Get a Full Hearing. For the most rapid advance of man, then, we need, primarily and essentially, the perfect realisation of those conditions, of which the imperfect realisation in the past has already sufficed for so much, though not for a tithe of what might have been. This is to say that, at all costs and under whatever external form of government, we must have a society in which the new gets a full hearing, and in which the conditions for the production of the new are as favourable as possible. The new is not good because it is new, nor yet is it therefore bad; neither is the old good because it is old, nor therefore bad. We must prove all things, new or old. In a savage society there may conceivably arise an observer of nature who would endow his tribe with new powers, but such a society is not conditioned for the production of the new. It promptly kills the inventor as a sorcerer or servant of the devil. Again, in such a society as that which France witnessed scarcely more than a century ago the old, however good and true and tried, was condemned simply because it was old. Either state of affairs is as fatal as the other.

We are attempting, as the reader observes, to encompass an infinite subject in the briefest of spaces. Our business, therefore, has been, as far as possible, to deal with principles, though we propose, before closing, to show how sociology must attack a definite concrete problem. When the choice lay between attempting to expound the principles which we have just discussed and, on the other hand, attempting a serial study of various well-marked forms of government, we could not doubt which to choose.

We Must Know What We Aim At. If we are to believe in science at all we must believe in the existence of principles, and if we do so we cannot be excused for ignoring them. We may leave to untrained minds the common forms of the controversies as to monarchy or oligarchy, democracy, the hereditary principle, and so forth. This is not that we are so foolish as to deny the immense practical importance and interest of these subjects, but it is that, as students of science, we entirely repudiate the common methods of approaching these problems. It must never be forgotten that, as we have pointed out, the sociologist has a purpose; he desires not only to discover what is, but, with the moralist, to discover what ought to be; and, lastly, to discover how what is may be transformed into what ought to be. Until you know what you are aiming at what is the use of arguments about democracy and monarchy?

The truth is that only among the very few has the evolutionary idea yet established itself. The majority still think of society statically, whereas the evolutionist must think of it dynamically, as he does of every other fact in the universe. Society for him is a something which moves, which has come from somewhere and is going somewhere. The pre-evolutionary thinker will take a given nation—a monarchy, perhaps—and will inquire whether monarchy "works" there. To his eye the people seem prosperous and contented. Very well, then, he will answer, monarchy suits them and is the best form of government for them. To the evolutionist such talk is the prattle of a blind baby. He knows that the static stationary society, though it may seem stable, is, relatively to the motion of all things, a decadent society. It, too, is moving, and moving downwards. The evolutionist cannot content himself with *now*.

Man Has Forever. The true answer of the evolutionist, we think, to those who study society merely for the present, who do not ask where we are going, and who do not realise how awful is the difference between what is and what might be—even amongst "a happy and prosperous people"—is to be found in a phrase from Browning's great poem, "A Grammarian's Funeral":

> "Leave Now for dogs and apes!
> Man has Forever."

Man has a future, compared with which his now is verily a now of dogs and apes. If there be those who find it in them to be contented with any society now extant or already extinct, *we* are not of their number. We have ideals; we have studied the past, not as men read gossip nor as they read a new novel, for its "strong human interest," but because we believe that in studying it we may discover principles which are no less than the principles of progress, and having learnt certain of these principles we propose to keep them steadfastly before us in studying all contemporary social problems—including, for instance, forms of government. Furthermore, those principles must be our criteria or means of judgment, and we shall ask of any form of government, not "Do the people like it?" not "Does it please the Chancellor of the Exchequer?" but "*Does it open or close—does it make broad or narrow—the onward way?*"

The Great Controversy of To-day. In the light of these principles, let us attempt briefly to discuss the present great controversy, practical and theoretic, between individualism and collectivism. Each of these words is capable of a good and bad interpretation. They mean different things in different mouths. But we shall endeavour here to make reasonable interpretations of both, and to see whether these ideas cannot be judged in accordance with our principles and whether, also, they do not each of them contain a truth, or half-truth, the union of which with the other would be fruitful of good.

It is this controversy, and not the controversy between the principles of monarchy and democracy, that really concerns society to-day. There may have been a time and a place for monarchy, but neither is afforded by the progressive peoples of to-day. It need hardly be pointed out that our own country is a monarchy only in name. We shall ignore Russia, therefore; and we shall also ignore Germany, which will become a progressive people in any real and great sense only when she has done with her abominable burden of militarism. We may confine ourselves to England, France, and America—peoples on the whole, despite terrible lapses, pacific and progressive, all alike essentially democratic. The common argument in discussing these large matters is an argument for and against democracy; but that is really out of date. More especially is it out of date, because it concerns itself with the form and not with the substance. The mere democratic form is not the vital thing. In our study of human nature and society have we not seen that even a military autocracy depends upon the will of the people who provide their autocrat with his army, thus almost warranting the idea that such a form of government is, in a sense, democratic? The really vital question is not the external form of government at all, but the mutual relations of the individual society.

The Two Kinds of Democracy. Thus it is possible to have two mutually opposed forms of democracy which, though under the same name, yet offer the most fundamental opposition that society can conceivably show. When we realise this we shall realise how absurd is the current argument for and against democracy, as if democracy were always one and the same thing. On the one hand, we may have an ultra-individualistic democracy, and on the other an ultra-collectivist democracy. Now, these are the two ultimately opposed forms of society. The supposed difference between autocracy and democracy is nothing compared with this vital and fundamental difference between democracies themselves.

We may take the United States of America as a fairly typical example of the one extreme. There, we find a society which regards individualism, utterly disqualified, as the only true social principle. There liberty becomes licence. The new certainly gets a hearing; personal energy and initiative are rewarded; but there is no qualification of this principle by its correlative half-truth. The individual is allowed, in the exercise of his liberty, to destroy not only the liberty but also the lives of his less able or energetic or fortunate fellows. And the social state approaches to anarchy. This is not the ideal anarchy of the future, when, human nature at large having reached the heights which now only the few attain, each man will live by an inner law that impels him to serve all others, but it is the anarchy of human nature in its present state, which is indeed lower than the angels.

The End of the State is Justice. On the other hand, certain parts of America, and certain aspects of life in England and France, afford us hints of the other social extreme. The nominal label, in the case of France, at any rate, is still democracy. But we here have forsworn labels and label-makers, and may get on to facts. In the ultra-collectivist state, which is represented now only by a very few barbaric tribes, but which played a great part in the early history of society, we find the chief character to be the absolute rule of all over each. The individual is the slave of the society; he must do as he is told for the good of the whole—this involving the amazing assumption that majorities are always right. The slave, of course, is a slave, whether his master be an individual, a bureau, or a mob. And the slavery of the individual to the tribe in primitive societies is, we may venture to say, not merely a noteworthy fact of such societies, but the explanation of the fact that they are primitive.

How, then, are we to frame the ideals of liberty and justice which combine the half-truths seen by these two extreme forms of society—the half-truth that the individual must be allowed to express himself and the half-truth that the individual, as we now know him, cannot be a law unto himself? We shall find what we desire in the great formula of justice laid down and magnificently elaborated by Herbert Spencer. The end of the State, he said, is justice, meaning thereby exactly what Lord Acton meant when he said that the end of the State is liberty; and justice is constituted when "*Every man is free to do what he wills, provided he infringes not the equal freedom of any other man.*"

The Music-hall Type of Mind. The primitive idea of justice is that of aggression and counter-aggression; if you have your fists free, I may hit you, for cannot you hit me back. That primitive notion, which is still found in the music-hall and in the music-hall type of mind, has nearly vanished, and there remains the great idea expressed above, which constitutes the ideal that selects, recognises, and mutually complements the partial truths expressed by absolute individualism and absolute collectivism.

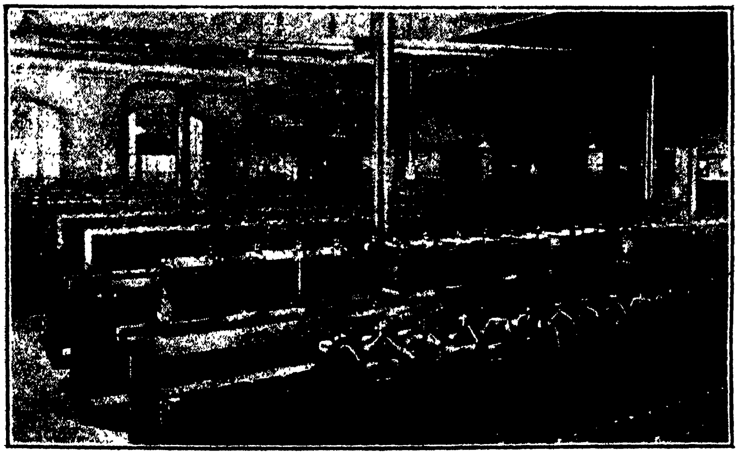
Repeaters. As the length of a telegraph line increases it is found that the speed at which signals can be transmitted through it rapidly decreases. It is, in fact, inversely proportional to the capacity per mile, and also inversely proportional to the resistance per mile, and as a consequence the signalling speed varies inversely as the square of the length of the circuit. When, therefore, the length of a circuit is so great as to reduce the speed below the maximum rate for the instruments, recourse is had to the use of repeaters—that is to say, the circuit is divided into two, and an intermediate instrument introduced which, on being affected by the signals from one section repeats them to the other, and *vice versâ*. In signalling from London to Edinburgh a repeater is introduced at Leeds, and in signalling from London to Dublin a repeater is introduced at Nevin, on the Welsh coast. The repeater is introduced at a point so that the products of the capacity and resistance of the sections on each side of it are as nearly as possible equal. In principle, it is merely an extension of the relay [see page 5067].

Figure **76** illustrates one of the most complicated forms. It is a forked repeater such as is used at Edinburgh on the news circuits already described; the wires from Glasgow on the west, and Dundee and Aberdeen on the north, meet at Edinburgh at the forked repeater, which is also connected to London. Another repeater is introduced on the same circuit at Leeds. As an interesting instance of the extent to which repeater working is possible, it may be stated that the Indo-European Telegraph Company maintain direct Wheatstone working between Manchester and Teheran, in Persia, by means of 11 intermediate repeaters.

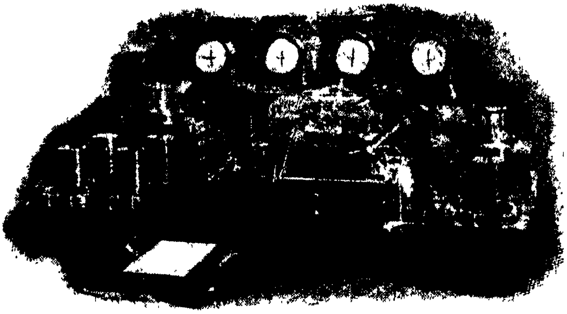


77. CENTRAL TELEGRAPH OFFICE, LONDON—ACCUMULATOR ROOM

Batteries. Until quite recently all telegraph circuits were worked by means of primary batteries, and at small offices this is still the case. Three main forms have been used—the Daniell, the Leclanché, and the Bichromate. These have already been described on page 465. The Daniell cells were used for local circuits—that is, between the sounder and the relay, and for such cases as duplex, where a constant current is required; Leclanché cells for needle circuits; and for long circuits, where the current consumption was considerable, the Bichromate was utilised. In determining the number of cells required for a given circuit, allowance has to be made for the resistance of the battery, as well as for that of the line and instruments, and a formula developed from Ohm's law [see page 61] is usually employed for this purpose. It is as follows:

$$N = \frac{CR}{1000E - Cr}$$

where N is the number of cells required, C the given current in milliamperes, R the total resistance of line and instrument in ohms, E = the electromotive force per cell in volts, r = the resistance per cell in ohms.



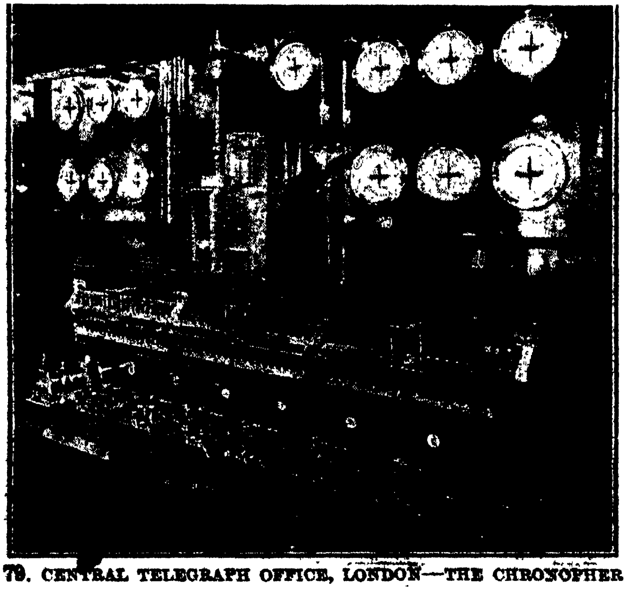
76. FORKED REPEATER

Accumulators. In all large telegraph offices primary cells have been displaced by accumulators, the change effecting a great economy in space and in cost of energy. Figure 77 is a very interesting view of the accumulator-room at the Central Telegraph Office, St. Martin's-le-Grand. It contains altogether 800 cells, and when these were introduced in 1899, no fewer than 23,000 primary cells were displaced. Accumulators have already been dealt with on page 3086. It will be of interest to refer to some other features of the Central

78. PART OF BASEMENT TEST FRAME AT CENTRAL TELEGRAPH OFFICE, LONDON

Telegraph Office, and it may be stated that the Secretary of the Post Office kindly allowed a special series of photographs to be taken for this publication. When the Post Office took over the telegraphs in 1870, 230 wires were led into the Central Telegraph Office; this number has now increased to 4,300, and special means have to be adopted for their proper handling. In **78** is shown a section of the basement test frame. The wires are first brought to the further side of it, which is not visible in the illustration, and arranged on horizontal bearers. They pass through this frame to the front side, where they are soldered to vertical strips of combined test springs, lightning protectors, and heat coils. These are all numbered so that ready access can be had to any wire for testing at this point. The wires are then distributed to the various galleries, and **81** shows the provincial test box on the third floor. The rectangular tablets are of ebonite pierced by small brass cylinders, the incoming wires are soldered to the rear of alternate horizontal lines on these cylinders. The cylinder above each line is connected to the instrument set, and on the front of the test-board two cylinders are connected together by the insertion of a small aluminium "U" link, from which this type of test box takes its name. A still later form of test box is shown in **80**. This is in one of the divisions, and it is made up of switch springs of the telephone form to be described in a later section. These take up less space than the "U" link form, and permit of greater flexibility.

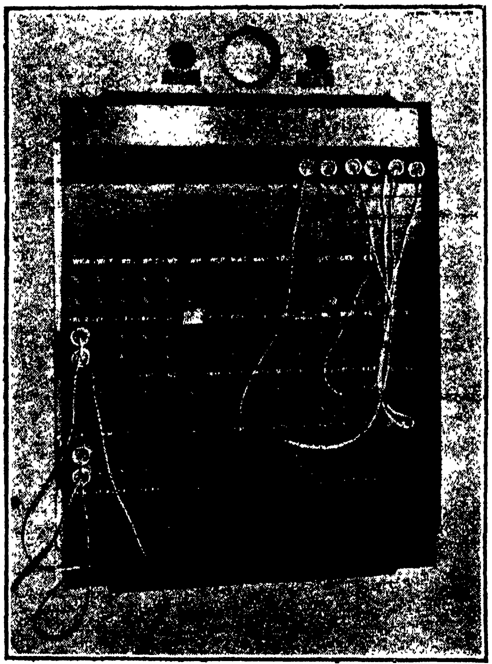
Correct Time. In **79** is shown one of the most interesting features in the Central Telegraph Office. It is called the *chronopher*. One line to each of sixty of the principal towns in the United Kingdom is carried through the set of switches which can be seen extending across the front of the board. Normally, these are connected through to the working sets. At two minutes to ten each morning the clock mechanism visible above the switches comes into action and slowly presses forward the long, horizontal busbar until these 60 lines are disconnected from the working sets and connected up to the special relay visible on the extreme left, which is in communication with Greenwich Observatory. Precisely at the hour of ten a current is received from Greenwich, which affects the time relay and sends out currents to master clocks, town clocks, and time guns situated at the towns aforesaid—as far north as Aberdeen, south-west to Penzance, and west to Waterford. Exact Greenwich time is in this way disseminated throughout the kingdom. The same current which actuates the chronopher relay passes on to Westminster and controls Big Ben. For towns other than those mentioned a less precise system suffices. Six repeating sounders are fixed on the front of the chronopher, and they are connected with various bells in the divisions which strike at the hour, so that the telegraphists, who are on the alert, can transmit the word "ten" to all the smaller towns. This same human relay system is in operation at all the provincial offices, so that the



79. CENTRAL TELEGRAPH OFFICE, LONDON—THE CHRONOPHER

chronopher instrument may be regarded as the centre of an immense spider's web, along every fibre of which at ten o'clock every morning a thrill passes.

London Intercommunication Switch. Until 1902, the system of centralisation and retransmission which has been described in connection with provincial circuits also prevailed in connection with London's own intercommunications. A telegram handed in at any suburban office was transmitted to the Chief Telegraph Office, and, after traversing its mazes by tube or by hand, reached another suburban circuit and was retransmitted. The competition of the telephone, with its prompt switching and instantaneous communication, made itself severely felt, and it became obvious that means must be found to shorten the time necessary for inter-city telegraphic communications. In accordance with modern methods, the telegraph took a leaf out of the book of its adversary, and an intercommunication switch on telephone lines, equipped with lamp signals and arranged for central energy working, was introduced. More than 300 London telegraph offices have been connected to it, and others are being rapidly added, and as it permits of direct communication between any two connected stations it is obvious that a great saving of time and also of staff has resulted from its adoption.



80 TEST BOX (SWITCH SPRING TYPE) AT CENTRAL TELEGRAPH OFFICE, LONDON

The Old Metropolitan Division. Under the old arrangements, the London suburban and branch offices, numbering nearly 500, were connected to instrument sets forming the Metropolitan Division. At four "check" tables, one at each corner of the building, the messages were sorted and marked for distribution by a staff of clerks whose knowledge of London's geography and the corresponding telegraphic avenues was simply stupendous.

In the year preceding the introduction of the switch the Metropolitan Division had a daily average of 102,000 transactions, of which number 54,000 were due to the reception of 27,000 messages *from*, and their subsequent transmission *to*, London offices. The new switch aims at eliminating the whole of these 54,000 transactions and at the same time effecting economies of time and space and plant.

Provision will ultimately be made for 300 switch wires to offices which collect only, 650 switch wires to offices which collect and deliver, and 200 circuits for receiving messages will be provided, making a total for the switch of 1,150.

The Morse sounder system is employed throughout, and this has necessitated changes at many offices and the training of the staff.

by glow lamps having switch springs above them to which circuits are connected.

Switch Offices. At each of the out stations there are a sounder and key and also a special key used only for calling the switch operator or for effecting a "clear" signal when finishing. It has a side plunger which actuates a star indicator when a call is made by its momentary depression. The star indication remains visible until the switch operator connects her sounder to the wire, when it disappears.

In concluding this Telegraph section, it will be of interest to give United Kingdom statistics for Post Office telegraphs and telephones for the years 1901 and 1906. They show at once the extent of and the trend of development. Telephones are included, and the great increase in the figures in these cases and also in those under the head of Underground is, of course, due to the development of the London telephone system.

Circulation Lists. It has also been necessary to supply to each of the offices two circulation lists, one containing names of streets, etc., and the other registered telegraphic addresses. The first of these contains no less than 30,000 entries, and the second 23,000. Figure 82 shows one section for three operators, and there are ten such sections. The bottom panels are occupied

NATURE AS A DOCTOR

Ill-Health and its Symptoms. Nature's Efforts to Keep Us Well. Symptoms and Treatment of Disease. False Systems of Treatment. Remedies

Continued from page 5412

By Dr. A. T. SCHOFIELD

WE shall, in due course, speak of the general features of disease, and go at some length into the various causes that produce it. We shall here consider the *symptoms*, the *diagnosis*, the *prognosis*, and the *treatment* of disease from a general standpoint.

The Symptoms of Disease. In the first place, there is no means of telling that a person is in ill-health at all but from symptoms. This is of great importance. These symptoms, or signs, are evidence that the man is ill. But this is only half the truth concerning them—the half with which we are most familiar. The other half, of which most of us have never heard before, is that symptoms also tell us if the patient is already being treated scientifically, and that *these symptoms are the very remedies that are being used for his cure.*

Symptoms arise from two causes. One set is the result of the illness itself, such as weakness, collapse, delirium, pain; another is the result of the actual methods of cure adopted by the *vis medicatrix naturæ*—the unconscious mind—for the relief of the sufferer. Such are temperature, cough, sweat, nausea, loss of appetite. There is a sense, indeed, in which *all* the symptoms, including even the weakness, pain, and delirium, may be regarded as protective and beneficial, even if not actually curative.

Symptoms, therefore, may be regarded, as a whole, as produced by the central governing force, partly for the protection and partly for the cure of the patient, and are, with few exceptions, beneficial and remedial. This is possibly new to a great many people, whose first idea in connection with a high temperature, for instance, is to lower it, or with a cough to stop it.

Nature's Treatment of Ill-health. Let us take two cases as illustration. A lady is sitting at dinner, when she is suddenly invaded by the germs of pneumonia. Symptoms at once set in. She shivers, her temperature begins to rise, and she gets into a fever. This tends to kill the germs and destroy their poison. She feels ill, and must leave the table; this is to make her acquainted with her state. She must undress and lie down; this leaves her lungs free and puts her at rest. She cannot do with light and noise; this ensures rest. She refuses all solid food; this is because she can no longer digest it. She bursts out into profuse perspiration; this is to prevent the fever from rising too high. She begins to cough; this is to keep her lungs free. Her breathing becomes more frequent; because it is shallow.

Here, then, are a number of symptoms, none of which a wise physician will interfere with, for he knows very well they are all beneficial. He may have been taught to "treat" them, but if he be wise the only way he will treat them is with respect.

The other case was given by Sir. F. Treves at Liverpool, and is of appendicitis. Here, indeed, every attack must prove fatal but for the rapid curative symptoms that supervene. The temperature again rises to kill the germs; the bowels cease to move to give rest; the abdomen becomes rigid to protect the tender area; an abscess forms to prevent the poison spreading; pain is felt at the spot to indicate the locality, and so on. All symptoms are beneficial, and represent Nature's efforts to cure the disease.

We will now briefly review the various classes of symptoms, which form two great divisions—the *subjective*, or those observed by the patient; and the *objective*, or those noticed by the doctors and others. We may divide the subjective symptoms into five classes—*sensory*, *motor*, *functional*, *mental*, or *phenomenal*.

The Great Value of Pain. The first of these symptoms is pain. Consider for a moment the value of pain. It is as useful as the red light on a railway. Where it is absent we are in imminent danger. A man who has lost feeling in his legs may burn them severely when asleep before a fire. The heart having no sensation, severe disease can develop unknown to the patient. Pain at once says something is wrong, and indicates the locality; without it we should not be safe for a moment.

It is of the greatest importance to have the seat, character, duration, and intensity of the pain accurately described. It may be boring, darting, cutting, dull, throbbing, or aching. It may be general or local. It may be fixed or shooting, constant or intermittent, severe or slight, superficial or deep. There may be tenderness in the part, or pressure may relieve it. As a rule, we say that sharp pains which are relieved by pressure are less serious than dull pains made worse by pressure. The sensations may not be those of pain, but of uneasiness, nausea, cold, with shivering (this is important). or of heat—general or local. Or there may be other sensations—a "ball" in the throat or stomach, irritation, aching, fulness, malaise, weakness, giddiness, or loss of sensation, partial or complete.

Amongst the *motor* symptoms are paralysis, partial or complete, generally described as local, stiffness, weakness, lassitude, involuntary, spasmodic, or painful movements, etc.

Functional symptoms include every irregular or imperfect action of any organ or special sense. The ears or eyes may be deaf or blind. There may be loss of smell or taste; the breathing may be laboured, short, hurried; the heart may palpitate or beat irregularly, and so on with every organ.

Among *mental* symptoms there may be delirium, mania, monomania, confusion, loss of memory, unconsciousness, excitability, apathy, despondency, and so on.

Under the head of *phenomenal* symptoms may be grouped definite states or acts that cannot otherwise be classed, such as cough, sickness, blood-spitting, running from the ears, formation of boils, tumour, or states such as bilious.

The greater part of these subjective symptoms are of a curative nature, as we have already seen. The remainder are the direct result of the disease. All seem to indicate the special illness the patient suffers from.

How Disease is Detected. We now turn to objective symptoms of disease—those observed by others. Our means of observation are sight, hearing, touch, smell, and experiment.

We notice first the general aspect and expression of the patient, the colour of the skin, the presence and character of any eruptions, the expression of the face, denoting ease or suffering, depression or excitement, the condition of stoutness or leanness, or wasting or bloodlessness, and many other matters. It is, indeed, here that the habit of rapid and accurate observation is so invaluable.

We must also notice the position of the patient —how he lies, sits, or stands, and how he breathes; the appearance of the eyes, of the tongue, and so on. The pulse, however, has now by no means the importance that it had before the days of exact observation.

Hearing tells us the character of the breathing, the voice and speech of the patient, including cough and its character, hoarseness, etc. But the ear is of special value when aided by the stethoscope, to hear and understand the sounds in the lungs, heart, stomach, etc. We notice also resonance or dulness by percussion.

Touch is an important means of objective diagnosis, and reveals many symptoms. We get a knowledge of the temperature, of moisture, of dryness, of size, shape, elevation, or depression of any part. We notice smoothness or roughness, pulsation, vibration, extent of movement, resistance, softness and hardness, and fluctuations, by which the presence of fluid is detected.

Smell and taste may reveal symptoms in certain cases. The general odour is often significant, and the special odour from any diseased part reveals decayed lung, cancer, etc.

Experiment includes weighing the patient, examining him with instruments, such as measures, thermometer, ophthalmoscope, laryngoscope, auroscope, specula, sounds, etc.; also by chemical tests of all sorts, and by electrical tests.

Nature's Unceasing Effort. Before leaving symptoms, the writer would repeat that Nature (the unconscious mind) is ever in disease seeking to adapt the disturbed balance of life to the environment, and causes the symptoms. Take the case of rheumatic fever, which is Nature's effort to get rid of a powerful blood poison, brought on by indigestion, bad air, cold, and damp. In doing so, one of the valves of the heart may get thickened, and cease to act perfectly. Nature therefore gradually enlarges the heart to meet the extra strain upon it, and the man suffers from an hypertrophied heart, a symptom which, so far from being hurtful, actually keeps him alive. If he be wise, he helps Nature by giving her less work to do by henceforth only "eating to live," instead of "living to eat," and all goes well. In fact, if the heart is overloaded, Nature makes another effort, and produces dropsy as a safety-valve to relieve the heart from too much weight of blood. This is another symptom beneficial in itself, but pointing, of course, to a grave danger. If the man still persists in his folly, Nature, having failed to adapt the life to its environment, has nothing left but to cease its efforts in the silence and stable equilibrum of death.

Danger of Interfering with Nature. While, therefore, we cannot observe too keenly and accurately the subjective symptoms in ourselves, or the objective symptoms in others, we cannot be trained to interfere too little; and this review of symptoms will be of great value if all who read it learn one lesson. The extent to which any interference is wise in domestic life will be considered in connection with the various diseases. These symptoms, ascertained by what the patient reveals, and what we are able to observe by physical examination, form the basis of our diagnosis.

The art of recognising the presence of disease, and of ascertaining from what form of disease a patient is suffering is known as *Diagnosis.* It is a matter of great interest and importance, for as it is founded on the symptoms and history of the disease, so it forms the foundation for prognosis and treatment; and the correctness and success of these entirely depend upon the accuracy of the diagnosis.

Only the simplest forms of disease can be recognised by the laity, and these not with certainty, so often is the meaning of symptoms misunderstood. A high temperature in a little child may not mean fever, but only a gastric disturbance; a pain in the heart in the same way may arise from flatulence, and so on. To form a correct diagnosis, therefore, is almost impossible, save to a medical man, and even he is often mistaken.

The Treatment of Disease. The foretelling of the course of disease is called *Prognosis.* Though a matter of the greatest importance to the sufferer, it can seldom be given exactly. One can often tell if a disease is curable or not; but the length of time it may take and the means that may have to be used depend on so many factors that great accuracy is impossible.

We will now consider the nature of the various remedies and systems of treatment. The old-fashioned way of classifying remedies and treatments was according to the effects they were supposed to produce. First of all, however, they were divided into two great divisions—*rational,* or those which produced effects by means we could understand and trace in the system; and *empirical*, or those which produced undoubted effects, but how we know not. Every physician employed both these classes of remedies; but, of course, the more he employed of the first division, and the less of the second, the greater the credit.

False Ideas of Treatment. Further, remedies and treatments were classed according to their supposed effects. We thus had *expectant* treatment, which really was most enlightened, and under other names is widely used to-day. It is founded on the principle that the *vis medicatrix naturæ* is often the only physician needed, the doctor neither assisting nor interfering with its operations, but only taking the fees. This system, good and enlightened in principle, becomes dangerous, and even fatal, in those cases which require immediate and prompt action. It has been the writer's lot to stand by a man's bedside and tell him he must inevitably die within a fortnight from complete blocking of the large bowel, due to his constipation having been treated on the expectant system.

The next form was *palliation*, which consisted in using means calculated to soothe and lessen suffering in those cases where a cure was not possible, but where life might be prolonged.

The *stimulant* treatment was founded on a doctrine that regarded most diseases as associated with, or dependent upon, a lowered state of the vital powers, and which required, amongst other things, a free and constant use of alcohol. One hospital physician, whose practice was founded on this treatment, often gave a bottle of spirits a day to cases similar to others that were more successfully treated in other wards without stimulants at all.

Obsolete Systems and Modern Views. The *lowering* (antiphlogistic) treatment is the opposite of the foregoing. It considered that very many diseases were due to over excitement and fulness of blood, and treated these by bleeding, blisters, purging, and the like. This was the most fashionable treatment in the seventeenth and eighteenth centuries, and it would be hard to say how many died from it.

The *elimination* system has more to recommend it, regarding disease as some poison introduced into the body, to be got rid of through the skin, kidneys, or bowels. The *hydropathic* system is largely founded on this.

The *alterative* system looks on diseases as vicious habits, which must be broken by violently "altering" the "course of Nature" on the "habit of the body." This system always employed very powerful drugs, often in dangerous quantities, such as mercury, arsenic, iodide of potassium, and the like. There were other systems, but these were the best known. In these days, such a classification is practically obsolete, and even the words empirical and rational are archaic. We are no longer sure that we can trace the real course of the action of drugs; we find the processes more complicated than we thought; and, besides all this, we are beginning to see that the action of no drug is purely physical, dependent solely on its chemical composition, but that we have to take into account constantly the personality and state of the individual at the time,—the amount of his vital power, and his nervous system, on which the efficacy of the drug partly depends.

Three Classes of Remedies. The simplest practical classification of remedies is according to their *nature* rather than their supposed *action*.

The division on this principle would be into three classes: *pharmaceutical* remedies, or drugs; *natural* remedies, which would include all mineral waters and spas, travel, climates, use of water, air, light, heat, electricity, etc., in every form, all sorts of physical exercises, including massage, riding, cycling, motoring, etc.; and, lastly, *psychic* remedies, which include every curative form of mind action. Let us take a brief but comprehensive survey of these three classes of remedies.

Here we must distinguish again between the rational use of drugs, which constitutes a science, and their empirical use, which is an art. Of course, the success of the treatment must depend, as we have said, on the accuracy of the diagnosis.

Until the last fifty years the most fanciful ideas prevailed both with regard to disease and drugs. The former were attributed to all sorts of processes and changes, wholly imaginary, that were supposed to take place in the body. The latter were credited with all sorts of fanciful properties, some being called hot, some cold, some contractile, some relaxing, some alterative; while some were considered of value owing to their noxious composition or taste, or their fanciful resemblance to the part affected. All this has long since given place to the *experimental* use of drugs, by which their exact effect was proved by experiments on animals, etc.; but the problem of the real action of drugs is so complex that pharmaceutical therapeutics will probably never become an exact science.

The Best Physician. In spite of the multitude of synthetic compounds made in America and Germany, laboratories for special diseases, by which our ordinary pharmacopœia is supplemented, the general use of drugs is less, and dependence on their effects not so great. The greatest physician in these days is the one who closely observes the action of the unconscious mind and copies most nearly the curative processes of Nature, using drugs sparingly, and never without a definite reason.

Amongst drugs which still hold their own as having a real specific value may be named various salts and compounds of mercury, arsenic, lead, sodium, potassium, iodine, chlorine, phosphorus, sulphur, carbon, iron; acids of various sorts; vegetable extracts, such as quinine, strychnine, opium, belladonna, digitalis; laxatives of all sorts; colchicum, podophyllin, euonymin, caffein, in addition to the swarms of artificial compounds, such as antipyrine, chloral ether, chloroform, phenacetin, paraldehyde, sulphonal, etc.

TECHNICAL DRAWING
continued from page 5421

DRAWINGS FOR A HOUSE

Preparing Contract Drawings. Site Plan. Plans of Floors and Roof. Elevations. Sections. The Staircase

By R. ELSEY SMITH

CONTRACT drawings form the basis on which estimates of the cost of carrying out any work are prepared, and are signed as forming an integral part of the building contract. They include a complete set of general drawings and sometimes detail drawings of portions of the work; the former are prepared usually to a scale of 8 ft. to 1 in., but sometimes, in the case of small buildings which are plain in character, to a scale of 4 ft. to 1 in. When drawings are made to the latter scale it is possible to show most work of a simple character with sufficient clearness to make detail drawings unnecessary except full-size details of all moulded work or special ornamental features.

General and Detail Drawings. When the general drawings are made to the scale of ⅛ in., detail drawings are required drawn to a scale of 2 ft. to 1 in., or, as it is more generally referred to, of ½ in. to 1 ft., or sometimes to larger scales for elaborate details; it is useful and desirable that some such detail at least should be included among the contract drawings; the more complete these are the less will be the likelihood of variations during the progress of the work.

Contract drawings are usually made on paper, finished in ink and fully coloured. This was the universal custom till recently; but now in some cases the drawings are carefully finished in ink on tracing paper or linen and then copies are made from them by use of the sun-printing process, and a set of these are fully coloured to form the contract drawings; other copies being supplied to the builder and, if necessary, to any sub-contractors.

This method of securing several copies from a single tracing is a great economy of time and labour, the principal drawback being that only black lines can be thus reproduced, and that, with some processes at least, there is a slight shrinkage noticeable in the copies. It is therefore very necessary when a tracing is to be reproduced by photo process that dimensions should be fully figured and the scale drawn on the sheet.

The Plan of the Site. The first step in preparing drawings for a building is to secure an accurate plan of the site. This is sometimes supplied to the architect, but must be checked. Often there is no such plan, and the site must be surveyed—a somewhat troublesome matter if it is already built upon. In towns where the whole site is to be covered with buildings the plan may be laid down at once to the scale to which the drawings are to be prepared; but in more open sites the ground may be plotted to a smaller scale depending on the size of the estate, but a scale of 22 ft. to 1 in. is often adopted. This plan should show the boundaries of the site, any buildings on adjacent sites that may affect the position of any new building near them, all buildings actually occupying the site, the north point, and any roads or paths. It should show the position and levels of any public sewers to which buildings on the site may be drained, and, where they can be ascertained, the situation of gas, water, and electric mains. The levels should also be indicated either by means of section lines or by a series of figures showing them at various points in relation to some well-defined datum line [5]. The levels of a site and the question of aspect have an important bearing on the planning in many cases.

A full set of contract drawings should include the following drawings:

A plan of the site. This may be to a smaller scale than the plans of the buildings, and on it the drainage is often shown.

Plan of the foundations. Drains are shown on this, if not on the site plan [7].

Plan of every storey in the building [6, 8, 9].

Plan of the roof.

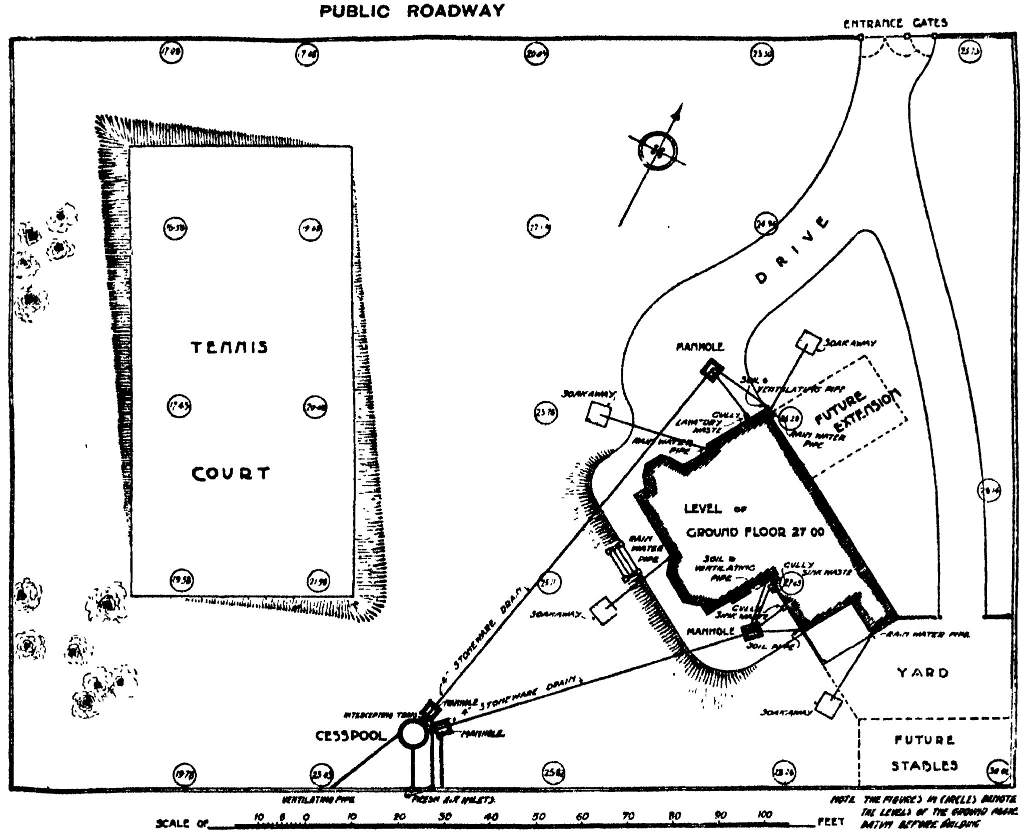
Elevation of each front of the building [10 and 12].

Sections sufficient in number to make the levels and construction clear [13 and 14].

The exact number of drawings will depend on the size and complication of the building.

Arrangement of Drawings. The actual size of the sheets will necessarily depend on the extent of the building and the scale used. For very large buildings sheets showing the entire buildings even to ⅛-in. scale are cumbersome to use and awkward to draw, and in such cases a complete block plan to a small scale may be prepared with advantage, the buildings being subdivided into well marked sections, and each treated as a separate building with its complete set of drawings. Where a building is small it may be possible, on the other hand, to arrange more than one drawing on each sheet of paper, and this facilitates reference. When this is done care must be taken to arrange the two drawings in proper relationship one to the other. For example: In the illustration on page 5544, the upper plan [6] is placed exactly over the lower plan [7] so that the lines of the side walls in the lower plan if carried up will coincide with those in the upper one. Should two elevations or an elevation and section be arranged side by side, care must be taken to see that the horizontal lines correspond in the same way [10 and 11]. It is not sufficient to make the drawings accurately to scale, but the leading dimensions should be figured on the plans and sections.

Plans. A plan is a horizontal section taken through the building. The plan of any given floor is presumed to be taken at a level between the floor and the ceiling ; but it is not necessary to assume that the horizontal plane cuts it at one fixed level and that only those features are shown upon the drawings which are cut by such a plane. All important features should be shown on every plan, including the doors and hatches, windows, piers, fireplaces with their hearths, internal windows or borrowed lights, or recesses for any purpose. Also any fittings that are to be fixtures and to be provided by the contractor, such as cupboards of various kinds, fixed tables, sinks, water-closets, lavatory basins, baths, urinals, copper, shelving, etc. . In cases where it is necessary to show two features coming one under the other, as, for example, a doorway with a window at a higher level, the lower feature is drawn solidly and the upper feature may be indicated by dotted lines. It is usual to mark on each plan the direction in which the floor joists are to run. This may be done by single or double dotted lines or by lines drawn in brown ink. Any sleeper walls carrying joists in the lowest floor may also be shown, and girders, whether of wood or iron, carrying upper floor joists ; but if of iron they would be indicated in blue ink usually. When the iron work is extensive or complicated it is often shown on a separate set of drawings or tracings used for this purpose. In complicated buildings there are other features that must be shown, but to avoid complication these are often indicated on a separate set of drawings and in different colours. Such features are: systems of passages or trunks used for ventilating complicated buildings; the main runs of pipes for heating buildings, including any coils or radiators; the run of main pipes for taking hot water to various fittings; electric mains, and gas mains.



5. SITE PLAN FOR A HOUSE ERECTED AT KENLEY

Nomenclature of Plans. The plan of the principal floor, which is usually arranged to correspond in level with the general level of the ground, but to be somewhat above it, is termed the *Ground-floor Plan* ; if there is a floor over the whole or a part of the site below this level, the plan of it is usually termed the *Basement Plan*, but if so arranged that a great part of it is above the ground level it is sometimes called the *Lower Ground-floor Plan.* If there are several floors below the ground floor level they may be described as the *First, Second, or Third Basement Plan.* The plan of the floor next above the ground floor is described as the *First-floor Plan,* and the plans of successive floors are termed *Second-floor Plan, Third-floor Plan,* etc., according to the number of storeys

above the level of the ground floor till the level of the eaves of the main roof is reached. The plan of the floor next above this level is termed the *Attic-floor Plan,* and if there is another at a higher level it is termed the *Upper Attic-floor Plan ;* more than two storeys in a roof are not, as a rule, allowed.

Foundation Plan. The foundation plan [7] is taken at a level below that of the lowest floor, and if the external walls have a projecting plinth this will usually be included in the thickness of such walls on this plan. Beyond the thickness of each wall are set out, on either side, the proper number of courses of brickwork for the footings of the wall, and beyond these the lines of the edge of the concrete. Under all ordinary openings in the ground floor the walls are not interrupted, but carried through as continuous walls; the footings and concrete are shown carried round all projections such as chimney hearths, piers, etc.

Basement Plan. Where a basement occurs the plan must show, in addition to the main building, any areas formed outside it to afford light to the basement windows, and any vaults under public footpaths. On all plans, walls are shown as having brick dimensions, no account being taken of the thickness of the plaster on the walls if there is any. The dimensions of rooms as figured on such plans represent the dimension between the unplastered walls, and the finished size of the room is a trifle less.

Ground-floor Plan. The walls on the ground-floor plan [6] are represented above the level of any plinth which may be indicated by a line outside the walls. If the wall is formed of more than one kind of material, this must be indicated by different colours on the plan. This plan at least should be fully dimensioned, and care must be taken, where a series of dimensions are given in different rooms, but extending from side to side or from top to bottom of the plan, that they correspond when added up to the extreme dimensions of the plan. Great care is required in arranging the plans of staircases to see that at all times there is proper head-room—*i.e.*, sufficient height between the upper surface of each step and the next flight or the ceiling immediately over it, to allow of persons passing up and down. This can only be secured by working out the plan and section conjointly. It is usual to number the steps from one floor to the next, and if there is a staircase descending to the basement as well as one ascending to the first floor, a portion of both flights is shown, and broken off by an uneven line: the same thing occurs on each of the upper floors.

The First and Subsequent Floors. The other floors [9] will generally resemble the ground-floor plan in character, but will show the building at a higher stage, and if the walls are reduced in thickness this must appear in the drawings. Any portions of the building that are not carried up will generally have the roof plan shown with the plan of the floor at the corresponding level. In arranging the upper plans care must be taken to see that the walls and divisions come over walls or divisions on the floor below, or when they do not that some adequate means of supporting them is provided. When the building is of a simple character, the attic floor may be combined with the roof plan [8], the lower parts of the roof and the plan of any rooms formed within it being indicated by full lines, while the roof above is indicated by dotted lines.

Elevations. An elevation is a geometrical representation of the true form of a façade [10 and 12]. It is not necessary that every part should lie in the same plane, but every part is represented truly to scale. The plane of the drawing is assumed to be parallel to the main face of the building represented, and any portions of which the plan is in a different plane are represented as if projected on to the picture plane. This may be seen in the representation of the bay windows on illustrations 10 and 12.

The elevation should show the finished level of the ground, all plinths, strings, and other external features, and the levels of all floors should be indicated by dotted lines. It is desirable that all features that will appear when the building is completed, such as soil and rain-water pipes, should be indicated, and the character of the materials to be used should be indicated by the method of lining the walls, assisted by colour.

Sections. A section represents the cutting of the building by a vertical plane [13 and 14]; but, as with a plan, it is not necessary to assume an absolutely rigid position for the plane, so in a section the position of the plane may be varied to some extent at will, so that it shall pass through special features. It must, however, be kept in a plane parallel to the main one, or a distorted section would be produced.

In fixing the position of the line on which any section is to be taken, it should be arranged to show all the most intricate and difficult work, and in particular to indicate all changes of level in floors, and the method of carrying any walls or partitions not resting directly on walls below. All parts of the building actually cut by the plane—the walls, floors, roofs, etc.—will be actually shown in section, while between these will appear in elevation one side or other of the various rooms, corridors, staircases, etc., so intersected, and the line should be in such a position as to make the utmost possible use of all these portions, as well as of the actual sectional parts. It is desirable, for instance, to show important chimney stacks, indicating by dotted lines the manner in which the various flues are gathered over and collected. In addition to complete sections, small sections of special features that would not otherwise appear may be often added to the sheet of sections or to a sheet of elevations as in 11.

It is very necessary to pay particular attention to the arrangement of staircases, and, as already pointed out, to work these in connection with the plans. In indicating staircases on sections it is particularly desirable to show complete flights by the use of dotted lines where the section would not otherwise enable them to be seen.

DENTISTRY AS A CAREER

The Qualities of a Good Dentist. The Nature of Dental Work. Various Methods of Treatment. The Filling Substances

Continued from page 5432

IF it be possible to form a just appreciation of the prejudices and preconceived ideas of the general public concerning dentistry from the opinions of a dentist's patients, it would seem quite needless to point the way and offer assistance to those who may wish to practise dentistry. For so great appears to be the repugnance which the career of a dentist excites in the lay mind, that one is tempted to believe that there is no one who will care to avail himself of the information and advice tendered in this treatise. It is important, therefore, that, at the outset, the popular conceptions should be carefully considered, so that, if possible, it may be fairly decided how far they are consistent with facts, or to what extent they must be deemed mere fallacies.

The Dignity of the Profession. The practice of dentistry, then, is said to be tedious—"back-aching" is the more graphic description—destructive to the health and eyesight, and disagreeable; it is suggested that it must surely be dreadfully monotonous, lacking both interest and variety, while even the most polite patient occasionally makes it clear that in his opinion a dentist who enjoys his work must be callous and indifferent to the sufferings of his fellow-creatures.

Now, these conceptions of the dentist's work, if they are considered to constitute more than a very partial statement, can be shown to be altogether inadequate and unjust. In the first place, they do not take into account what may be called the dignity of the profession, the importance of the dentist's work to the community, the value of his skilful services to the state and to mankind. Yet this is a very serious omission. On the one hand, the absence of teeth, or the presence of stained or decayed teeth, in the front of the mouth constitutes a peculiarly distressing disfigurement; while, on the other hand, the absence of efficient grinding teeth, or the presence of diseased teeth and gums, at the back of the mouth, constitutes a distinct menace to health. Such conditions are inimical to health, not only because they render impossible the efficient mastication of food, but because they result in the infection or poisoning of whatever food is taken into the alimentary canal.

process of digestion. Here the food is broken up and thoroughly ground to pieces in such a way that the digestive fluids can thoroughly penetrate and soak the mass. In the mouth, too, should take place the thorough mixing of the food with the saliva, which not only constitutes the first stage in the process of efficient digestion, but is also the best preparation of the food for the action of those other digestive fluids of the body which are subsequently to come into contact with it. When effective grinding teeth are absent these important functions are of necessity more or less imperfectly performed, the digestion of the food is more or less faulty, and the nutrition of the patient suffers in consequence. Where, in addition, the teeth are much decayed or foul, and the gums diseased, the patient swallows with every mouthful of food a quantity of disease-forming micro-organisms and their products, while the odour of his breath gives some indication of the extent to which he is poisoning the atmosphere which others are constantly breathing. Such being the case, no one need be surprised at the frequent association of ill-health with bad teeth, for, although a few may for a long time, owing to their great natural powers of resistance, ward off serious ill-health, yet, as decay of the teeth is the commonest disease that flesh is heir to, an immense amount of suffering, sickness, and diminished efficiency for useful work must be directly attributed to disease of the teeth and gums.

Avoidable Tortures. It is significant that in a recent inquiry conducted by a Royal Commission the evidence of the dental surgeon afforded the most direct and positive testimony to the physical degeneration of the people of these islands. It must have been difficult, indeed, to compress the mass of evidence which any experienced dental surgeon would have at his disposal. Generally speaking, the condition of the teeth can only be described as appalling, and this is especially true of the teeth of the lower classes. Very largely owing to utter ignorance concerning the close relationship existing between the condition of the teeth and of the general health, reckless neglect seems to be the rule, and the aid of the dentist is sought only when the tortures of toothache render life unendurable. Yet these results are certainly avoidable, and, even when they already show themselves, it is possible to keep them in check and to effect in most cases a complete cure. It is not necessary to detail here the numerous unhealthy conditions which spring from bad teeth; but it is important

e how much

indirect, of

Here, then, is the dignity of the dentist's work. His calling constitutes him one of the custodians of the health of the community. In this respect his services are second in value only to those of the doctor; and if at times he can only effect a durable repair of the ravages of decay at the cost of some discomfort to his patient, he has at least the consolation of knowing that he is saving his patient not only from severe pain, but from the risk of serious illness or debility.

The Interest of Dental Work. Again, the popular opinion that the practice of dentistry must be exceptionally monotonous is largely fallacious. It should be remembered that dentistry is essentially a progressive science and a progressive art. Both in the study of the diseased conditions with which he has to deal, and in the practical methods of manipulation with which he combats them, there has been in the past few years an enormous advance, and the dentist who wishes to keep abreast of his day will find that his special branch of surgery will make large demands upon his time and study. It is true also that he is constantly dealing only with teeth ; but his patients fail to recognise that in each day's work probably no two teeth dealt with present quite the same problem for solution. And it would be wrong to argue that the work of a dentist must be lacking in interest as compared with that of a doctor because the dentist has to confine his attention to one small part of the body. The same method of reasoning might be applied to a discussion of the comparative interest of the work of a general practitioner and of a specialist in some particular branch of medicine or surgery.

Dentistry, or dental surgery, as it would be better to call it, should be studied and practised as a special branch of surgery, and if this is done no dental surgeon need complain of the lack of variety and interest of his work. To complete the comparison of medicine and dentistry as professions it should be added that, whereas the practice of general medicine is still held to confer a higher social status upon the practitioner, the public recognition of dentistry as a branch of surgery is only a question of time, and is rapidly becoming more general, while the dentist, if his work is tedious, possesses two very real advantages in that his hours of work can be fixed, and that, for the man of average ability, success is more easily to be attained.

The Good Dentist's Qualifications. It should be emphasised that, whereas financial success is not invariably the proof of merit, and still more is not commensurate with the degree of merit, it is probably true that there is little satisfaction in mere financial success. The really successful dentist must have earned not only the reward of his labour but the regard and respect of his patients, as well as the approval of his profession.

What, then, are the qualities which make for success in dentistry, and what ought to be considered disqualifications ?

Fortunately, it may be asserted that, whereas certain natural qualities fit a man to a peculiar degree for the work of a dentist, there are few qualities which cannot be acquired to a degree which ensures average success. Apart altogether from the question of general health, a disproportionately large hand, marked clumsiness of the hands, seriously defective eyesight, and —since the course of education is long and expensive and the examinations of a somewhat high standard—a dull brain, ought to be considered positive disqualifications. To persist in spite of them is to court disaster, involving the waste of valuable time and money.

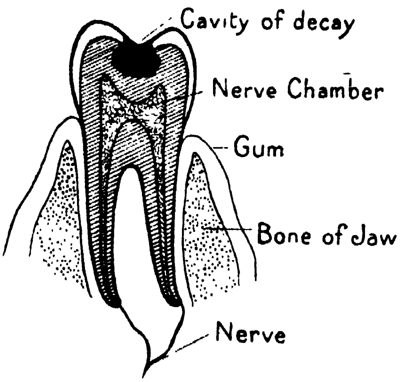
Practice and Theory. Turning to the positive aspect of the question, it cannot be too strongly emphasised that dentistry is both a science and an art. Without debating at any length whether it partakes more of the nature of a handicraft or a learned profession, it may be confidently stated that the dentist who has not acquired both manual skill and intimate theoretical knowledge of his subject is very imperfectly equipped, and must not expect to be successful. The student who gives his attention to the practice to the entire exclusion of the theory may become within his narrow limits an excellent mechanic as far as mere dexterity is concerned, but he cannot fail to be essentially a rule-of-thumb workman, who will generally do the second best for his patient owing to sheer lack of knowledge of the conditions with which he has to deal and of the means of dealing with them which science places at his disposal. Moreover, to say that dentistry is a science is to affirm that the efficient practice of dentistry demands not only the acquisition of detailed knowledge but, what is equally essential, the habit of thinking scientifically, and of constantly basing deliberate judgment upon a careful study of all the circumstances of every case.

But if it be true that such a dentist is incapable of rendering the highest form of service to his patient, it is at least equally important to bear in mind that a lack of manual skill is an even more serious defect, and that the student who neglects his opportunities of acquiring dexterity in his work makes a still more serious mistake than he who has too little of the scientific spirit in his methods of working.

Managing a Patient. These two, then, are essential qualities of the good dentist, without which he certainly does not deserve, and is not likely to attain, success. We have considered already the power of forming right judgments, of deciding what in the circumstances is the best course to pursue in dealing with each case as it presents itself, and it might be thought that, if equipped with these three qualities of knowledge, judgment, and skill, the dentist would be fully capable of dealing with the problems which his work involves, and that success would therefore be assured. That these qualities in themselves are not sufficient is due to the fact that the dentist has to deal not merely with teeth but with individuals. Were it otherwise the dental art would indeed present few difficulties, though it would as certainly be robbed of much of its interest.

But the fact that the dentist has to treat human beings, and not merely a number of teeth, complicates not a little the problems he has to solve. And it does so in two ways. In the tooth he has to deal with an organ of exceptional sensitiveness, which demands not only the gentlest handling of which he is capable and an intimate knowledge of the means of diminishing sensibility, but also a peculiar skill in " managing a patient." So far is the dentist from being callous to the suffering of others, that a man cannot in any sense of the word be a successful dentist unless he is keenly alive to the pain his manipulation may cause, and unless he strives constantly to minimise it.

The Dentist's Greatest Difficulty. Individuals differ widely in their sensitiveness to pain and discomfort, and in their capacity to endure them for the sake of future comfort and benefit. Some display a fortitude creditable in the highest degree, while others show an impatience and want of control which would be contemptible were they not pitiable. Ostentatious sympathy may destroy for the time the little self-respect which some patients possess, whereas a little firmness may brace a nervous and excitable patient in an extraordinary manner. It need hardly be said that, when he desires to be firm, the dentist must be careful to avoid even the appearance of brutality, for his aim must always be to inspire his patient's confidence, not only in his skill, but equally in his desire to do what is best with the least possible pain. To be successful he must acquire, in addition to technical skill, a knowledge of human nature, the power of rapidly judging temperament, and of accommodating himself to temperament. To reconcile his ambition to do good and permanent work with his desire not to give avoidable pain is, perhaps, the greatest difficulty with which the dentist has to contend.



1. SECTION OF TOOTH, SHOWING NERVE CHAMBER, CANALS AND CAVITY OF DECAY

It may seem superfluous to add that the dentist needs a large fund of patience, and that, if the difficulties of his work or the exasperating conduct of his patient have exhausted it, he must assume a virtue which he no longer possesses. A word should be added on the desirability of acquiring the habit of absolute fairness, almost of generosity, in all that is said to patients with reference to work done by other practitioners. This quality, like that of conscientiousness in working, the best kind of patient will always learn to admire and respect, and both will earn in time their own reward.

A Day in the Life of a Dentist. Two other matters call for consideration. One is the quality of invariable courtesy; the other that of scrupulous cleanliness. They do not need to be enforced by any argument. They are absolutely essential, and no greater mistake can be made than to suppose that they can be assumed at will for the occasion. They must be part and parcel of the man.

There is the greatest practical need for what has been said of the popular ignorance of the realities of the dentist's work. It is important that no young man should take up the work of preparing himself for practice under an entirely false impression, and it may be helpful to give some idea of a typical day's work in a dental surgery.

The first patient may be waiting for the dentist when he arrives in the morning; and it transpires that he has spent a night of such agony as only those familiar with toothache at its worst can realise. With little warning, severe pain may have come on soon after the patient retired on the previous night, and raged almost without cessation. None of the simple domestic remedies have been, in his case, at any rate, of any avail; and, in spite of great repugnance, the dentist's assistance is sought at the first opportunity, with the determination to "have it out."

The First Problem of the Day. Here, then, is the first problem of the day. The dentist has to form an opinion upon the cause of the pain, and to decide upon the best method of dealing with it. Without entering deeply into technical details, it may be said that pain of this kind is probably due to one or other of two causes. Every reader who has spent much time in the dentist's chair has heard of what is called "the nerve." This bundle of blood-vessels and nerves, which travels through a minute hole at the end of the root of a tooth, and thence through a tiny canal which runs through the centre of the root from end to end, finally spreads out to form a clump in the centre of the tooth itself [1]. When decay attacks a tooth there may be little or no pain until the hollowing-out has gone so far that a cavity is formed nearly as deep as this clump of blood-vessels and nerves. Even at this stage there may be no pain unless the nerve is injured by an instrument or some hard particle of food bitten into it. More often, however, a nerve which has in this way been exposed by the hollowing out of decay will become inflamed and extremely painful, and, if left to itself, will most likely inflict intense suffering for days, when it may cease in a mysterious way to hurt any longer. In such a case the nerve is said to have died, and is, in fact, no longer a part of the living body. It is like a limb which has been amputated, or a finger which has been frost-bitten. In other cases the inflamed nerve gradually ceases to be painful, and there may be relief for a few days, weeks, or months, and then, perhaps, another severe attack, during which the nerve finally dies.

Danger of Neglecting a Dead Nerve. Unfortunately, the pain which a nerve is capable of causing is not limited to the time when it is alive. The presence of that bundle of dead tissue in the tooth and in the root or roots of the tooth, constitutes a real danger. This dead matter, if it be attacked by micro-organisms or microbes—which are exceedingly common in mouths that are neglected—will decompose; and, unless the gases and poisonous juices which result from decomposition can escape through the cavity which decay has made, they will pass through the minute hole at the end of the root and cause an inflammation of the bone and soft tissues of the jaw. This inflammation is the beginning of an abscess, or collection of matter, which ends by opening upon the surface either of the gum or of the skin of the face, chin, or neck. This, then, is the second cause of severe toothache, and the first work of the dentist is to determine which condition is responsible in any particular case.

The Folly of Indiscriminate Extraction. Having determined this, partly by asking questions calculated to elucidate the circumstances of the case, and partly by a careful examination of the tooth and its surroundings, the dentist has next to decide how best to relieve the pain. An inexperienced patient, having suffered acutely from such a tooth, will no doubt strongly urge that the offender should be removed, and, unless reasons can be urged against this, the suggestion will certainly be followed, since it is obviously the quickest and simplest method of giving complete relief. But the modern dental surgeon, and with him at least a section of the public, has come to realise that the extraction of teeth, though in most cases a beautifully simple way of getting rid of pain, is an operation not lightly to be undertaken—an operation, indeed, which should be regarded only as a regrettable necessity in certain cases. When a tooth is still capable of rendering useful service, every attempt should be made to preserve it. A wise patient will prefer to endure some discomfort rather than sacrifice a useful tooth to the forceps, and the conscientious dentist will do his utmost to dissuade a patient from extraction if the tooth can be permanently and usefully preserved without making an unjustifiable demand on the patient's endurance.

The Method of Treatment. Naturally, the method of treatment will vary with the cause of the pain. In a case of exposed or inflamed nerve, the dentist will remove some of the decayed tooth-substance which more or less fills the cavity, and, having located the spot at which decay has attacked the nerve, will apply to it a small quantity of one or other of the various nerve-destroying substances at his command. Most of these preparations contain arsenious acid, which has the peculiar power of destroying the vitality of the nerve, combined with other drugs which are added for the purpose of relieving the pain temporarily, until the arsenious acid has had time to complete its work. The nerve-destroying preparation is then sealed in the cavity with soft gutta-percha or some other temporary stopping material, and the patient dismissed, an appointment being made for another visit.

If, on the other hand, the case [illegible] one of incipient abscess, the decayed substance is more freely removed, and the cavity enlarged until the dead nerve material is accessible. As much of this as can be removed without much grinding and cutting is then cleared away, and a little pad of cotton-wool soaked in carbolic acid or some similar antiseptic is placed in the cavity previously occupied by the nerve. This is then sealed in as before, and an appointment made for another visit.

It will be understood that in dealing with either of these conditions, especially with an exposed nerve, the utmost delicacy of handling is demanded. The tooth and its surroundings are acutely sensitive, and it should be the dentist's aim to manipulate them as little as may be consistent with relieving pain. Such a patient, having probably passed a sleepless night, and being inclined, perhaps, towards extraction, deserves to be treated with every consideration and to be saved from all unnecessary pain.

Filling the Tooth. Let us suppose that the next patient is one who a week ago was in much the same straits as the first patient found himself in this morning. The nerve-destroying material was applied, and relief obtained. There may have been for a short time during the succeeding night or day a return of pain of varying intensity, but the tooth is quite comfortable again now, and the next step towards the permanent saving of it may be taken.

This is the filling of the tooth. The operation consists of the removal of the inflamed nerve, which is now dead, and subject, therefore, to decomposition. This is performed by means of tiny barbed steel bristles, which are inserted into the nerve canal and withdrawn when the sharp barbs have caught the nerve tissue firmly, drawing it out of the canal. The complete removal of the dead tissue having been performed by means of these bristles and by fine drills rotated in the foot-engine with which most people are acquainted, the tiny canal is filled with little lengths of gutta-percha or some other filling material, and steps are taken to fill the cavity which decay has made, and which may have been enlarged by the dentist in order to enable him to obtain access to the canal or canals of the tooth. This, then, is the place to refer to the difficult problem of the choice of the most suitable filling materials.

The Ideal Filling Substance. Anyone who considers the matter carefully will perceive that a substance which is to serve the purpose of a tooth-filling should have certain qualities. It should be hard enough to withstand the force of biting and chewing; its appearance should resemble that of the tooth in which it is inserted, so that it cannot be detected; it should form an insoluble, water-tight, non-poisonous plug which is not irritating to the delicately sensitive nerve close to which it is placed. It should not conduct heat or cold readily; it should be naturally adhesive to the sides of the cavity; and it should be capable of being inserted so quickly and painlessly as not to be disagreeable to the patient, and so easily that failure to fill the tooth well and permanently is almost out of the question. Unfortunately, although many years of research have been devoted to the attempt to discover a substance combining all these desirable qualities, there is nothing known which can be called an ideal filling material. Many of the substances at the dentist's command possess some of the qualities desired, and in a few cases almost all the qualities needed are found combined in one material. The dentist has, therefore, the task of deciding in each particular case which qualities are least essential and which seem most desirable, and of making his choice in accordance with the judgment he has formed.

Common Filling Materials. The substances in common use as fillings may be classified.

METALS. Pure gold in various forms and pure tin are examples.

CEMENT. Formed by mixing certain acids, as phosphoric acid, or the acid salt zinc chloride, with certain salts such as zinc and magnesium oxides, the compound becoming hard in the course of a few minutes.

AMALGAM. The result of combining mercury with certain metals such as gold, silver, copper, zinc, or tin, the compound becoming hard within a period which varies from a few minutes to several hours.

GUTTA-PERCHA. Used in various forms.

PORCELAIN. The mineral which is the result of fusing compounds of silica by great heat.

It is impossible within our limits, and unnecessary for our purpose, to enter at length into a discussion of the properties of these substances, which are more fully treated in CHEMISTRY. The subject is an intricate one, involving much technical knowledge, which it should be the aim of the student to acquire. It will be seen, however, that the choice of the most suitable of them for each individual case gives scope for the exercise of mature judgment, and that the skill requisite for the manipulation of so many different substances to their best advantage is of a high order. The majority of them, possessing little adhesiveness, require that the cavity into which they are to be inserted should be specially prepared by cutting grooves and dovetailed holes, in order to render it retentive in form.

Removing the Dead Nerve. The next patient may be one for whom the growth of abscess has been cut short in the manner described when the requirements of the first patient were being discussed. Here, again, the first object which the dentist sets before himself must be the complete removal of the dead, and, in this case, decomposing nerve-tissue. The latter will be in a more or less fluid condition, and great care has to be exercised in its removal to avoid driving any of the poisonous material through the aperture at the end of the root into the tissues surrounding the tooth, where it may, as we have seen, cause serious inflammation or abscess. The canals having been thoroughly cleansed and filled, the problem again resolves itself into one of the choice and insertion of a filling material.

Following this there may be a succession of patients presenting teeth in which the process of decay has not advanced so far, and the dentist may decide that the tooth can be safely filled without first destroying the nerve. The advantage of this procedure consists in the fact that the full nutrition of the tooth is unimpaired by the loss of some of the blood-vessels which supply it, the life of the tooth being consequently prolonged. The risk of the procedure is that a filling material, if placed too near the live nerve, may irritate it, and thus cause inflammation and severe pain.

During the day's work, also, there will probably be several visits from patients requiring some slight adjustment of the artificial teeth they are wearing, which, owing to some change in the mouth, are causing discomfort.

Dental Work Among Children. The dentist may also be consulted with reference to children in whose mouth the teeth, as they appear through the gums, are taking up unusual positions, causing disfigurement or pain, and he will have to deal with these either by extraction or by adjusting to the mouth various forms of appliances which correct the irregularity by pressure upon the offending tooth, which guides it to its proper place.

Finally, there is a class of patient who present an entirely different problem. These people have in many cases been recommended by a doctor to seek the aid of a dentist in curing the diseased conditions which are largely the result of deficient or diseased teeth. By far the commonest of these conditions is dyspepsia or indigestion. Such a patient's mouth may present an appalling picture of the ravages of decay. Many of the teeth may be so extensively decayed that nothing remains of the crown. Other teeth are coated with a hard substance called tartar, while many spaces indicate how often a tooth has been sacrificed to the forceps for the relief of pain.

The Dentist as Doctor. For such a patient the dentist may have to perform a variety of operations. Some diseased and useless stumps may need extracting, during which the patient may be rendered unconscious by the administration of anæsthetics; for some it may be possible to construct and attach an entire tooth-crown of gold; the tartar has to be removed, and the gums restored to health; cavities in teeth which it is decided to preserve must be filled, while it is often necessary to supply the place of teeth that have been lost by artificial ones made of porcelain and mounted upon plates of gold or some other substance carefully adapted to the jaws.

Such, then, is a short survey of a day's work in a dental surgery, and at the cost of repetition it may be added that the mechanical and surgical problems alluded to are generally complicated by some degree of sensitiveness, ignorance, prejudice, or even obstinacy on the part of the patient. It is needless to say, perhaps, that outside the actual work of the surgery the conduct of a busy dental practice involves the writing or superintendence of a considerable correspondence and book-keeping.

A NEW DYNASTY FOR ENGLAND

The Work of Sir Robert Walpole. Wolfe's Capture of Quebec. Canada and India. The Gordon Riots. The Ministry of William Pitt

By JUSTIN McCARTHY

THERE was no direct heir to the throne when Anne died, and the supporters of the Stuarts and those of the House of Hanover hoped to snatch the crown. The House of Guelf, to which George the Elector belonged, traced its descent to the days of Charlemagne. One of its members had married a daughter of Henry II., and thus founded the Brunswick family.

George the Elector was born at Hanover on March 28th, 1660. He was the eldest son of Ernest Augustus of Hanover and of the Electress Sophia, daughter of James I., and was thus connected with the line of English sovereigns. On Anne's death he was proclaimed King of Great Britain and Ireland. He had been Elector of Hanover since 1698, and had fought in the campaigns of Marlborough. In 1682 he had married his cousin, the Princess Dorothea of Zell. The marriage was unhappy, and ended in a divorce.

Sir Robert Walpole. George I., on his accession, immediately nominated an entire Whig Ministry, with Charles Townshend as Prime Minister. He was, however, soon succeeded by the famous Sir Robert Walpole, who, during the reign of George I., practically ruled the country. He had held office in Queen Anne's reign, but was found guilty of peculation, expelled from the House, and imprisoned in the Tower. In 1715 he became First Lord of the Treasury and Chancellor of the Exchequer. He resigned two years later, but on the death of Stanhope he again filled both offices, which he held until his resignation in 1742, when he was created Earl of Orford.

He was a great financier as well as a great statesman, and it was his financial genius which prevented the most serious consequences from following the failure of the South Sea Company—the "South Sea Bubble."

The story of the Stuart risings in the reigns of George I. and George II. has already been told. In 1723 Bolingbroke returned to England, joined the opposition to Walpole, and contributed to the "Craftsman," a political publication of that time started by Bolingbroke and Pulteney. A brilliant politician of that day was Carteret, afterwards Earl of Granville, another bitter opponent of Walpole.

George II. George II., who succeeded his father as Elector of Hanover and King of Great Britain and Ireland in 1727, was born on November 10th, 1683, and was declared Prince of Wales in 1714. He took a more active part in the government than his father before him had done, but during the early part of his reign Sir Robert Walpole was still the ruling power. George II. was not a man of any great qualities, and his private life was, like his father's, immoral, although he was much influenced by his wife. England was at peace with other countries until the death of Walpole in 1745. During that time many treaties were made, one with Spain in 1729, known as the Treaty of Seville, which was confirmed two years later by the Second Treaty of Vienna. In the same year Townshend retired because Walpole compelled him to reject the Pension Bill.

The Tax on Wine and Tobacco. Walpole wished to follow his tax on salt by one on wine and tobacco, but this was so unpopular that he had to abandon it. The Definite Peace of Vienna was signed in 1738. Walpole retained his majority, and Bolingbroke went to France, where he remained until 1742. In the following year occurred the famous Porteous riots in Edinburgh, caused by the hanging of a smuggler called Wilson. Captain Porteous, of the City Guard, commanded his soldiers to fire on the mob who had rioted, and some of the people were killed. Porteous was condemned to death, but on being respited by the Government was seized by the rioters and hanged. The Lord Provost was dismissed, and the city had to pay the widow of Porteous £1,500.

In 1737 the Prince of Wales quarrelled with the King about his jointure, in which the King's party were successful in Parliament. Two years later Walpole was compelled to declare war against Spain, but the expeditions which were sent were not successful. In 1742 the Government came in with such a small majority that Walpole resigned office, and in the next year Henry Pelham became Prime Minister. The question of the Austrian Succession now came up again, and a large army of English and Hanoverians was sent to the Netherlands. George II. took part in the war, and commanded the English and Hanoverian army at the Battle of Dettingen in 1749, where he greatly distinguished himself. No English king has since taken part in a battle. Two years later the King's second son, the Duke of Cumberland, fought in the Battle of Fontenoy, in which the French, under Marshal Saxe, were victorious. In this war the Irish Brigade, composed mainly of Irish exiles, fought on the side of the French. The Treaty of Aix-la-Chapelle ended the war in the Netherlands in 1748.

The Seven Years War. In the meantime Pelham had resigned and returned to office. In 1751 the Reform of the Calendar was introduced, and in 1753 Hardwicke's Marriage Act. Pelham died in 1754, and Newcastle became Prime Minister. The Seven Years War began in 1756. Minorca was captured by the French, and Newcastle resigned. In the same year a Coalition Ministry was formed, with Pitt as Prime Minister. The King had for a long time refused to receive Pitt as a Minister, but had at length been compelled to give way, as it was impossible to form a Government without him. Pitt thus became Secretary of State and Leader of the Commons.

The Seven Years War went on with varying success. The Duke of Cumberland was defeated at Kloster-Seven, and compelled by the French to capitulate. In 1758 Ferdinand of Brunswick succeeded him, and in the following year he won a great victory at Minden. In September of the same year Admiral Boscawen defeated the French at Lagos. One of the great events of this year was Wolfe's capture of Quebec. This victory laid the foundation of one of England's finest Colonies. The leaders on both sides were killed in this struggle—the Marquis of Montcalm in the hour of defeat, and Wolfe in the hour of victory. In November Hawke defeated Conflans off Quiberon.

Clive, the Hero of Plassey. In the meantime the great English soldier, Robert Clive, who has been called the real founder of the Anglo-Indian Empire, won the famous victory of Plassey, and in 1759 the siege of Madras was raised, and Coote took Wandewash.

George II. died on October 25th, 1760—the year following these famous victories.

George III., his grandson, succeeded as King of Great Britain and Ireland and Elector of Hanover. He was born in London on June 4th, 1738, his father, Frederick, Prince of Wales, having died before George II. In 1761 George III. married the Princess Charlotte of Mecklenburg-Strelitz. George III.'s reign was one of the longest in English history. In it occurred some of the greatest events of all time, and in it, too, lived some of the greatest of English statesmen. George III. was very different from either of his predecessors. He had no intention of leaving the country in the hands of his Ministers ; he wished to rule himself. The Minister who had most influence with the King was Lord Bute, who was, however, extremely unpopular with the English people. The King was violently opposed to the Whigs, and in 1761 the " King's Friends," as they were called, succeeded in driving Pitt—afterwards the famous Earl of Chatham—from power.

The Prosecution of Wilkes. The Peace of Paris, in 1763, reversed the policy of Pitt. George Grenville was Prime Minister in 1763, and was succeeded in 1766 by Rockingham. Pitt, now Earl of Chatham, would have been willing to become the head of the Government but for an illness which made it impossible, and the Administration was continued by the Duke of Grafton. The prosecution of John Wilkes for the famous No. 45 of the " North Briton," the paper in which he criticised the King's Speech, made him the most popular man in England, and his name has ever since been associated with liberty. Wilkes was at this time Member for Aylesbury, but as he did not obey the order of the House to attend in his place he was expelled in his absence. In 1768 he stood for Parliament for the City of London, but, being defeated, he at once became candidate for Middlesex, and was elected by an overwhelming majority. Wilkes was sentenced to a fine of £1,000 and imprisonment for twenty-two months, and a new writ was issued for Middlesex; but Wilkes was again returned. Whenever the law declared him disqualified to sit in Parliament the electors of Middlesex again elected him, and when at last, in 1774, Parliament was dissolved, and Wilkes was again returned, the contest was not re-opened, and he was allowed to take his seat.

The Gordon Riots. Lord North became Prime Minister in 1770, and remained so for twelve years, during which the country was in reality ruled by the King, of whom North was merely the instrument. These years were disastrous for England. The policy of coercion used by the King's wish towards the American Colonies led to the American Revolution, the story of which is told later. In 1778 Lord North wished to resign in favour of Chatham, but this the King refused to allow, and the death of the " Great Commoner " in the following year left the King free to pursue his own policy with regard to America, in spite of the remonstrances of North and the resignation of several of his colleagues. The Gordon Riots began in 1779 by a meeting in St. George's Fields of a body of 50,000 people to present a petition for the repeal of the Catholic Relief Act. The mob, encouraged by Lord George Gordon, forced their way into the House of Commons. The House adjourned and the mob dispersed, but committed all manner of acts of violence. Gordon now thought his followers were going too far, and tried to restrain them, but it was too late. The Commons met after the adjournment on June 6th, and decided to consider the petitions, but the same night the mob broke open Newgate and released the prisoners. The King behaved with courage and resolution, and the military were immediately employed to put down the riot.

Fox's East India Bill. Notwithstanding the King's dislike of the Whigs, there was now a Whig Ministry, and in 1783 the Coalition Ministry of Charles James Fox and Lord North came in, resolved to break the Royal authority. The King determined to appeal to the country against the Government, and by unconstitutional means procured the rejection of Fox's East India Bill. Parliament was dissolved, and the elections resulted in a victory for the King over the Whigs. William Pitt, the son of Chatham, formed a Government in 1783, and under his administration England was powerful and prosperous, and the popularity the King gained in consequence was entirely due to the genius of his great Prime Minister. The King's mind became affected in 1789, but he soon recovered. The public rejoicings at this event were, perhaps, due more to distrust of the Prince of Wales than to any enthusiasm for the King; and the outburst of the great revolution in France had the effect of inducing many of the moneyed classes to support the Throne. But the lower classes suffered much from repression and injustice, and were consequently glad to welcome the new democratic doctrines which were gradually spreading over Europe.

A NEWSPAPER IN METAL

The Foundry. Stereotyping. The Papier Mâché Process. Quick News Methods. The Autoplate. Electrotyping. The Dalziel Process. Finishing Blocks

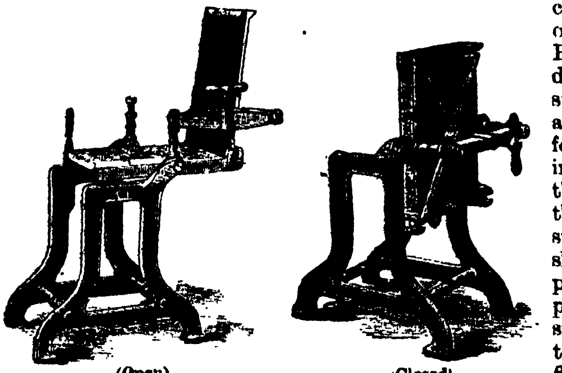
By W. S. MURPHY

THE process of printing wears out type, every impression flattening the surface by an imperceptible yet definite degree. Type is costly, and the printer naturally seeks out means to lessen the wear and tear on it. Other considerations prompt the idea. For instance, many books run to 600 pages, and no printer could allow all that amount of type to stand in pages. Of course, the obvious remedy is to print off the first formes, distribute the type, and use it for the following portion of the book. But if another edition of the book is called for, it all requires to be set anew. By taking a mould off the pages, from which any number of reproductions can be cast, all that expense and trouble may be obviated.

The Paper Process. The paper process may be resolved into four parts: (1) the composition of the "flong"; (2) forming the matrix; (3) casting the plate; (4) finishing the plate.

Typefounders have so simplified the furnishing of the stereotype foundry that a complete equipment could be carried in a wheelbarrow; but as concentration, in this case, produces complexity, we will go into a large modern foundry, where everything can be seen on an expanded scale. First there is the *metal-pot*, in which has been melted an alloy of lead, tin, and antimony, heated by a fire or gas; next stand the *hot plate*, a table with an iron top, hollow, for heating from the inside by steam or gas or coal furnace fumes, and over the end of the table the *matrix-press*, looking in every respect like a gigantic letter-copying press. Firmly based on its thick legs stands the large iron-topped *imposing table* [32]; near it is the *chase-rack*, holding a number of chases, ranging in size from large quarto to little things capable of holding a small card. Over a bit, out of the way of the founding operations, we see the machine department, with circular saw [31], cutting lathe, bevelling tool, and shaving knife. On the benches and tables lie brushes, shears, and various small implements. In small offices, the hand shooting-board and plane, shown in 28, is used. Scarcely observable, but most important, sits the *paste-pot*, with its brush, and on the bench near lies the store of tissue and blotting papers, without which the paper process would be impossible.

28. FLAT SHOOTING BOARD AND PLANE



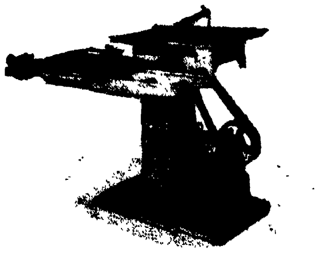
(Open) (Closed)

29. CASTING BOX

30. BEATING BRUSH

Making the Matrix. This array of tools and appliances will become intelligible as we proceed. The forme is brought in from the composing-room. If it is a large forme, the stereotyper usually breaks it up into smaller sections, the unit preferred being two pages. Damping the type to make the letters cling, the workman unlocks the forme, sets the clumps round the first section, and locks it up. He now prepares the *flong*. On a sheet of thick blotting-paper a thin layer of paste is brushed, and upon it a sheet of tissue-paper is evenly laid. Another application of paste, and another sheet of tissue, and then another two sheets pasted as before, compose the flong. Oiling the surface of the type, the workman lays his flong over it. This done, he puts a linen sheet over the flong, and, taking a long brush [30], begins to beat the flong into the type. The linen cover protects the soft, pasty composition, while conducting the blows of the brush bristles. Beating the flong demands dexterity, supple play of wrist, and fine judgment. A few unsteady or irregular strokes ruin the whole thing. When the flong has been sufficiently beaten, a sheet of stout wrapping-paper should be pasted on the back to strengthen it, and then the forme, with the flong on it, is carefully removed to the hot plate. Protected by a few layers of blanket, the forme is run under the press, which is screwed tightly down on it. In a few moments the press is unscrewed, the forme drawn out, and the matrix cautiously skinned off the face. Having been tightened, the forme is sent back. Pasting a flap of brown paper on the bottom of the matrix, the workman stretches it out on the hot plate under weights at each corner to dry.

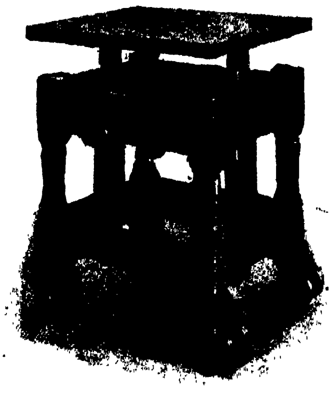
Casting the Stereotype Plate. When the matrix has been thoroughly baked, it is trimmed and made ready for the casting-box. The *casting-box* [29] is merely two thick iron plates, loosely hinged together at one end, fitted with closing clamp at the other, and mounted on a stand with swivels and springs that hold it in either a horizontal or vertical position. For the reception of the matrix the casting-box is put in the horizontal position, and the upper plate lifted back. On the level plate the baked matrix is laid, and round its three sides flat bars of steel, an inch broad and $\frac{1}{8}$ in. thick, are set. The upper plate is brought down, and a mould formed. Firmly clamped, the casting-box is turned to the vertical position. The flap we saw fixed to the matrix now lies over the mouth of the casting-box, and forms a feeding-apron for the metal. Having filled his ladle at the melting-pot, the caster pours the metal into the mould. Lead settles and cools quickly. In a minute the mould is opened, and a bright new plate comes out.



31. CIRCULAR SAW AND BEVELLING MACHINE (R. Hoe & Co.)

Trimming and Squaring the Plate. When the stereotype plate leaves the mould it is not ready for printing. A quantity of superfluous metal hangs about it, and other finishing touches are needed. Clear off the tags and rims with the circular saw [31], a toothed disc of steel set on a spindle within an iron table and driven by power. Our plate is too thick and the back too rough. For remedying these defects we have the planing machine or shooting-board and plane [28]. Rasp the top and bottom of the plate with a file to the depth you see necessary as a guide to the tool. Otherwise it may shave off too much. When the knife has passed over the plate it is of the right thickness and as smooth as glass.

If you look at an old stereotype plate, you will see that the edges are smooth and slanted or bevelled, whereas a plate fresh from the saw has a rough and straight edge. Besides, the sawn plate is seldom exactly square. The inventors have foreseen the need, and provided squaring and bevelling machines in numbers. The best and simplest consists of a movable iron table, fitted with screws and gauges for fixing the plate, set against a vertical spindle, capable of being driven at enormous speed and armed with a triple knife. Protect the face of the plate from the iron table by a pad or blanket, set it true in position, and let it move slowly along the whirling knives. In a few moments a finished plate results.



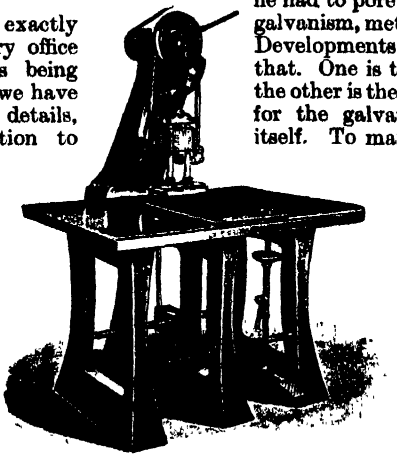
32. IMPOSING AND BEATING TABLE

Quick News Methods. Book-printing is rather a leisurely business. A day or two lost in the production of a book matters very little. With the newspaper the case is altogether different; it must be out every morning to the minute. Four large sheets, containing as many words as an ordinary novel, have to be set, stereotyped, and nearly a million copies of them printed in the space of a few hours.

The storm centre of this cyclone of labour is the foundry. As every page comes in on the trolley table there is a sudden rush of busy men, and the foundry becomes the scene of arduous labour.

Yet the stereotyper has not been caught unawares; he has been ready for the rush. Sheets of flong have been prepared and cut to page size, and lie waiting between damp cloths. The huge metal-pot is at the proper heat; the hot press awaits the forme, and the casting-box stands in position. It is round, like the segment of a circle, and this segment fits the circumference of each cylinder of the great rotary printing machines which will shortly be rolling off the newspapers at the rate of 90,000 per hour.

Working Against Time. The advertisement pages come in early, and they are cast in a more deliberate way than the late news pages. But the appliances and methods are the same. The forme comes in on the trolley, or table, and the workmen promptly slide it on to the imposing stone, or table. A swift brush with oil makes the type surface glisten, and then the flong hides it from view. Two men rapidly beat the flong into the type with brushes. Or, if the equipment is up-to-date, a flong-beating machine [33] performs the operation even more quickly. A thick sheet of paper is pasted on the back of the flong. Further protected by a flannel sheet, the forme is run under the roller geared at the end of the table, which deepens the impression on the flong [34]. Pressed and dried in the way formerly described, the matrix passes into the circular casting-box, and is cast. The finishing tools in the newspaper stereotyping foundry are automatic, as a rule. The *trimming saddle* is a curved block, equipped with cutting tools at end and side. On this the plate is fixed, and the knives quickly shear off the tags and margins on one end and side. To turn the plate round takes no time, and in another moment the whole plate is trimmed. But the back of the plate may be rough and uneven, and our flat planer is of no use for that curved thing. A planer has been devised to meet the need. This is a lathe with circular bed and circling knife. Laid face downward in the circular bed, the back of the plate yields its irregularities to the cutting tool, which rapidly moves in the same circle as the surface of the machine cylinder. The first stereotype plate can be produced complete in ten minutes, and subsequent plates in a much shorter period.



33. BRUSH STEREO-MATRIX MOULDING MACHINE
(Whitehead, Porteous & Co.)

No newspaper office is exactly like another, and in every office improvements are always being devised. For that reason we have purposely avoided minute details, and confined our description to the general features of the process.

The Autoplate. Rapid as the process of stereotyping for newspapers has become, the demand is for processes more rapid still. Short though the pause is between the locking-up of the formes and the coming of the stereo plates down the lift, it occurs just in the period when seconds are precious. The obvious remedy was a stereotyping machine, but it was easier to point to the way out than to invent the machine. In course of time, however, the desired time-saver appeared in the shape of the machine known as the "Autoplate" [35]. This machine consists of a casting mechanism and a series of finishing mechanisms which automatically co-operate in one machine to make the casts and finish them. It runs at the rate of between three and four plates a minute, and turns out a better quality of printing plate—with a harder and finer surface—than it is possible to make by hand. The improved quality of the plates is more particularly evidenced in pages containing illustrated matter, by reason of their being cast under great pressure.

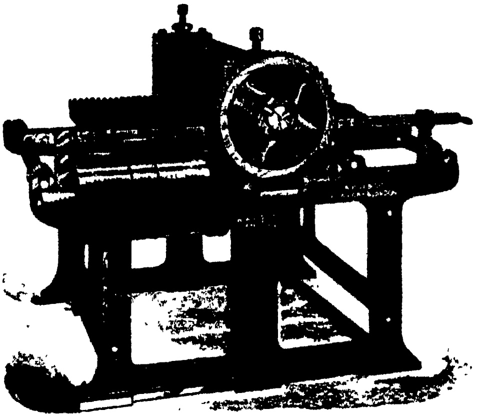
In the casting mechanism, at one end of the machine is placed the matrix. The operator, by the turn of a lever, starts the machine casting, and it proceeds automatically until the desired number of plates has been made and sent to the finishing devices. Then the matrix is removed, and another inserted, an act which requires but an instant of time.

During the operation of the machine the matrix is cared for automatically; and having been once inserted and secured, it requires no further attention until the full quota of plates is cast. The mechanism is so constructed that the matrix is manipulated with the utmost gentleness and precision, and a large number of casts can be made from a single mould without injury to it.

This, the latest of large inventions in the printing world, has supplied another link in the long chain of machines by which the printing process is carried through with scarcely the touch of a human hand, save in the direction of the mechanical powers.

The Science of Electrotyping. The electro-room used to be the arcanum of mystery to the ordinary printer. Here processes were carried on which he had no means of understanding. To get even an inkling of the secret he had to pore over dry textbooks on electricity, galvanism, metallurgy, chemistry, and mechanics. Developments in two directions have changed all that. One is the growth of technical education; the other is the substitution of the electric dynamo for the galvanic battery in the electro-room itself. To manage a galvanic battery properly a man required a clear knowledge of its principles and action, and this involved a smattering at least of chemistry and metallurgy as well as a grasp of galvanic theory. Even now the student would do well to study those sciences, if he desire to become master of the electro-room. As a groundwork he should read studiously the articles in the SELF-EDUCATOR on Metallurgy, Chemistry, Electricity, and Electrical Engineering, with special reference to acids in Chemistry, silver and copper in Metallurgy, and galvanic action and electrolysis in Electricity. In the electro-room of the present day the work is practical, and may be learned like any other trade.

The Discovery of Electrotyping. About 1839 three men, Professor Jacobi, of St. Petersburg, C. J. Jordan, of London, and Thomas Spencer, of Liverpool, appeared to claim credit for discovering that the deposit of a metal electrically corroded might by the same action be deposited on a mould with electrical affinity. This meant the discovery of electrotyping.



34. POWER STEREO-MATRIX MOULDING MACHINE

The "London Journal" for April, 1840, appeared with an electrotype plate, and Savage's "Dictionary of Printing," published the year following, gave several specimen plates produced by the process.

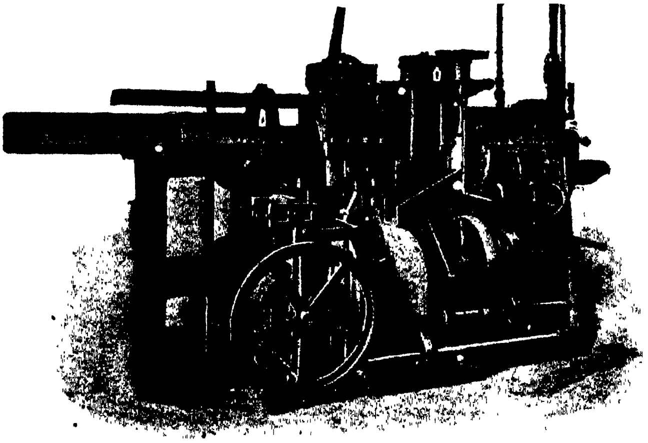
The process of electrotyping may be divided into six acts. (1) Moulding the forme;

(2) trimming the mould; (3) treatment of the mould in the trough; (4) releasing the shell; (5) backing the shell; (6) finishing the plate.

The Electro-room. The furnishing of the electro-room differs very much from that of the foundry. The equipment is larger, for the process is double. Here we have all the appliances and machinery for casting a plate and the apparatus required for forming the wax mould and depositing the electro besides.

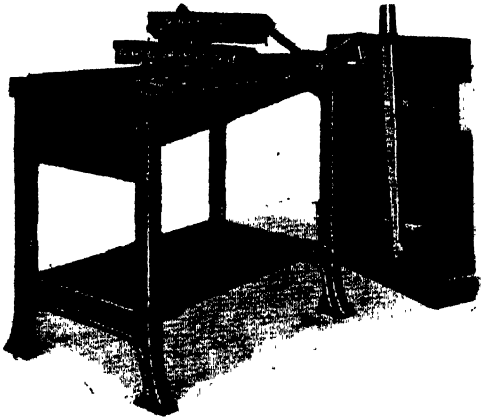
The forme is prepared in the same way as for stereotyping, but the locking-up apparatus is different. Wooden quoins and furniture should not be used in the electro-room, and cast-iron chases are unsuitable. Wrought-iron chases, heavy and strong, fitted with screws for locking up, are the best and simplest. When screwed up and cleaned, the forme is covered with blacklead brushed on to a high polish.

Wax is the main substance of the electro-mould. Every firm has its own favourite composition, but this may be taken as a fair average: 20 lb. beeswax, 3 lb. Venice turpentine, 8 oz. blacklead. The *melting-pot*, heated by a gas-ring, sits in a flat iron plate. A water-jacket round the pot distributes the heat evenly—a consideration with such a substance as wax. The wax is now poured into a moulding-case—a sheet of lead with a flange a quarter of an inch in height all round. Within a few seconds the wax has hardened, and the mould must now be pressed on to the forme. Many forms of press are used for this purpose. The essential qualities of a *mould press* are power and evenness of pressure. No matter what form of press he uses, hydraulic or toggle, the workman has to learn by practical experience how to adjust the pressure to his need. After being pressed the mould is removed from the type, and put into the hand of a skilled operator, who *builds* it up, cutting down excrescences, filling up defects, and rendering the mould solid and clear.



35. THE AUTOPLATE MACHINE

Showing a cast in the rough, one undergoing the last of the dressing operations, and a finished plate. The matrix is inserted at the right-hand end and the product delivered at the left, while the refuse is caught by the waste-box, as shown.



36. BLACKLEADING MACHINE

(The cover has been removed)

The Blackleading Machine. The builder has done his best, and now the mould goes on to the *blackleading machine* [36]. Outwardly this machine looks like a large box set on legs. In the box we find a moving lattice-table, and across it a pair of long-haired brushes fixed by two arms to a driving shaft. The mould is laid face upward on the table and sprinkled with blacklead. Then the box is shut, the lattice table moves to and fro, the brushes rapidly vibrate on the face of the mould, and bring it to a high state of polish. A few finishing touches with a camel-hair brush, and a rub up with the hand brush, make the mould ready for the plating trough.

When a workman loves his work he is not content to follow mere routine practice, getting the job through anyhow; he thinks out little improvements, and adds them to the process. One eminent practitioner, for instance, has found that by coating the back and outer parts of the mould with an insulating varnish, better results are obtained. Another has devised a method of using sulphate of copper in contact with iron filings, so as to produce a thin film of copper on the mould, before it goes into the trough, thus facilitating the formation of the plate very considerably.

The Bath. The *trough* or bath [37] should be made of wood, 3 ft. deep, 4 ft. long, 2 ft. wide, lined with sheet lead, or thick plate glass. Across the trough strong copper wires are fixed for holding the moulds, while at the side, within the trough, hang the copper plates called the anodes, literally the ways of the electric current, and practically the decomposing metal which is distributed on the mould. Water, strengthened by sulphuric acid and sulphate of copper, fills the trough. The moulds are hung in the solution by means of copper hooks linked on the rods. Now the electric current is switched on from the dynamo, and the work of electroplating has started. With the old galvanic batteries the process took at least twelve hours for an ordinary plate, but the current of the dynamo makes a thick plate in less than half the time.

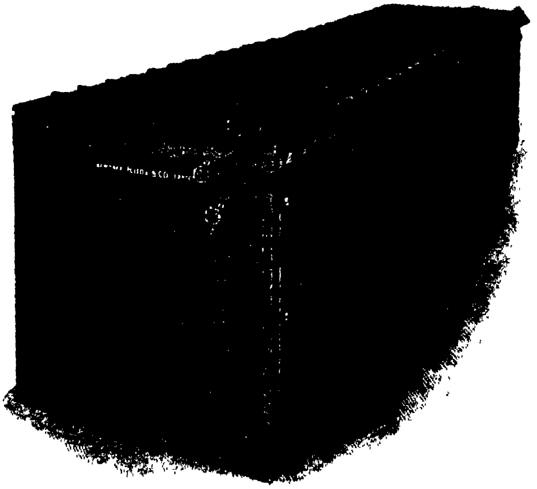
Making the Plate. The shell has formed a thickness of $\frac{1}{32}$ in., and is ready for removing from the bath. Taking the mould from the solution, the operator puts it under a stream of hot water, and frees the shell. After close examination and mending of faults, if any, the shell is laid on the backing pan, a shallow, oblong iron tray, with handles at both ends.

No amalgam of lead will join on to copper, and the backing metal is composed of lead, antimony, and tin. How is the difficulty to be got over? The electrotyper has already answered the question by finding in granulated tin a metal combining readily with both metals. Having been sprinkled with enough tin to cover the shell with a thin film, the pan is suspended over the square metal melting-pot on hooks geared in a frame above, and slowly let down into the molten metal. As the pan comes within the heat of the pot the tin melts, and spreads all over the inside of the shell. Then the pan is lifted on a level frame, and molten lead poured on to the required height.

The finishing of an electro-plate requires more delicate handling than the dressing of a stereotype plate, but the appliances and methods are practically identical.

Superseding the Electrotype. As may be readily understood, the foregoing process, consuming six hours of time, hardly contented the publishers of illustrated journals. Up till 1891, however, it seemed scarcely possible to do better. Common stereotype plates could not be made to reproduce fine illustrations, and the electrotype was the only apparent alternative. But in that year, Mr. Harvey Dalziel invented a process which completely changed the aspect of affairs, and gave into the hands of the printer a new and highly efficient method, capable of producing plates as swiftly as stereotyping, and as finely as electrotyping. Dalziel's process was invented in 1891. Previous to this date all high-class illustrated productions had to be produced by the expensive and lengthy process of electrotyping, which, a sa general rule, took about six hours.

The Dalziel Process. Dalziel's invention consists of a specially prepared plastic mixture (the ingredients of which are his secret) spread on a sheet of prepared paper. This is impressed as a mould on the blocks or formes required to be reproduced. So perfect is this mould that it yields facsimile the finest detail in the original half-tone or other blocks. The stereo-plate is made by running a specially prepared hard metal into the mould. These two operations take less than one hour, the result being equal to, if not better than, the finest possible electrotype. When a very large number of impressions is required from Dalziel stereos, they are dipped in a nickel depositing bath for a further period of 15 to 20 minutes.



87. ELECTROTYPING TROUGH

The merits of the invention may be appreciated by the fact that many high-class publications, such as the "World and His Wife," are printed entirely from these stereos.

Mounting Plates. Stereotype, electrotype, and all kinds of metal plates require to be mounted on a bed of wood or metal to make them equal to type in height. Various forms of blocks, or mounts, have been ingeniously devised. Typefounders and engravers who make a business of supplying illustrations to the trade usually mount them on solid mahogany, professedly of type height, though sometimes the printer finds good reasons for questioning the validity of the profession. [See TYPEFOUNDING.] Wood is not so reliable as metal, the wetting and drying, heating and vibrations to which formes are subjected in the various processes tending to warp and split even the best wood. Of late, metal mounts have come into almost universal use for stereotype and electro plates. Different patents are used, but the principle of them all is nearly the same. Metal block-mounts in two parts readily lock together, making up to different sizes, and clasping the four sides of the plate by narrow rims and brass catches. These blocks or mounts not only make mounting an easy matter of putting two pieces together; they also facilitate the work of imposing successive formes. All that the workman needs to do in such case is to unlock the forme, loosen the catches, lift out the plates already printed, and put in the fresh plates.

VARIETIES OF BASKETS

The Square Basket and its Manufacture. Ornamental Borders. Oval and Fruit Baskets. Workbaskets. Wicker Chairs and Crates. Toys

BASKET-MAKING continued from page 5490

AS a general rule, the framing of a *square basket* is much stronger than the skeleton of a round one, though, of course, small square baskets may be built up on very fine lines, like those shown in **5** and **15**. Suppose we elect to make a square basket 18 in. by 12 in., or thereabouts. As many square baskets are shallow, this one need not be deeper than 8 in.

The Bottom of the Square Basket. Selecting eight unwatered sticks 21 in. long, and about ½ in. in diameter, we straighten those of them which may be crooked with the commander [**2**, M, page 5489]. The two thickest are placed in the screw block [**3**], about 11½ in. apart., and fixed in position. Next, the others are put into the grip of the block, the thinner ends alternating with the thicker, to balance. It is obvious that the difference between the diameters of all the sticks must be as slight as possible; but a slight tapering is unavoidable. Having securely fixed the bottom sticks by their ends in the block, the next thing is to begin filling up.

The sticks standing up vertically in the screw block, we take two rods, fairly long and equal, and begin by a *pair*. Lay the first rod flat against the front of the second stick from the left hand side, the butt projecting a little over the third stick. While pressing the butt firmly against the second stick with the left thumb, bring the rod round behind the outside stick to the front, and then round behind the second stick, crossing the butt, and round to the front of the third stick. The projecting butt can be fixed behind the third stick. Introducing the butt of the second rod behind the third stick, and beside the other butt, bring it round in front of the fourth stick. The first rod, if it is to pair regularly, must come behind the fourth stick, and so we now have a pair of rods working over each other. At the outside stick to the right hand the pair are twisted back to start another row of weaving, and they are woven together across the breadth, making a sound base for this side of the bottom.

5. BORDERING A SQUARE BASKET

Filling up the Bottom. The whole bottom might be filled up by a continuation of the *pair*; but the common way is to fill up with *randing*, or for coarse work, *slewing*. With a single rod the weaving is continued to and fro across the sticks, till within about an inch of the end. A precaution has here to be observed. The natural effect of the pulling force of the woven rods is to draw the sticks closer together; if that tendency were allowed to go on unchecked, we should find one end of the bottom several inches narrower than the other. Practised workmen keep the structure in shape by the eye, but the beginner has not acquired that sense. A simple gauge may be made with a rod, bent at both ends to the size. Applying this at intervals to the bottom, as the work of filling up proceeds, the basket-maker keeps his work straight. Having filled up to within a short space of the end, we apply another pair of rods in the same fashion as was done at the beginning. Some consider it enough to work a doubled rod over that end; but for the sake of symmetry both ends should be made alike.

The Sides. When the bottom has been firmly woven it is taken out of the block, and the protruding ends by which it was held cut away close to the weaving, the remainder left being about 18 in. long. Next we select the stakes for the sides. For a basket this size we require eight for each end, and thirteen for front and back, making in all 21 pairs of rods. The stakes for the ends are cut at the back to a long point, and the point of each is thrust into the weaving of the bottom, one beside each stick. Like the stakes of the round basket the side stakes are given a slight cut on the inner sides, and turned sharply up close to the weaving.

The stakes at front and back are treated differently. It is necessary to drive the stakes through the outside bottom sticks. Make holes with the bodkin in the stick, at equal distances apart; sharpen the ends of the stakes, and drive them through, taking care not to split the sticks. This done, prick up each with the knife, on the side next the stick, and turn upwards. In order to keep the stakes from falling away at all angles, gather the top ends within an improvised hoop or holder.

Why Baskets are so Strong. We wish to make the basket capable of bearing a good weight and standing some wear. We therefore form the bottom courses with *wales* of three rods. The basket should be held firm on the workboard by a bodkin or iron weight. Put the first rod in between the first and second stake to the right, and bring it round between the second and third. Insert the second rod between the second and third stakes, and bring round between the third and fourth. Do the same with the third rod, passing it in between the third and fourth, and bringing it back between the fourth and fifth. Now begin weaving. Carry the first rod across the second and third, bring it round behind the fifth stake, and out to the front again. Naturally, the other two rods pass round the successive stakes, the second round the sixth, and the third round the seventh. Each rod is taken in turn and passed behind the stake next to the one already passed. Once we have made a beginning with such a method of weaving, the rest is easy, because it is simple repetition. Having made the breadth of *upset* we think necessary, the *walc* can be finished off evenly, and the single stroke called *randing* adopted to fill up the greater part of the sides.

and Borders. We might

ing nearly to the very top, and then work in a pair to finish off, relying on that and the border to keep all tight. But another waling course is considered better for strengthening the head. A strong and ornamental course can be made with four rods worked one over and after the other, in the manner already described. When well done the waling resembles a rope in appearance, and gives a firm backbone to the rest of the structure.

The simplest and most easily-learned border is that shown in our illustration of the square basket [5]. The stakes have not been cut off at the height of the weaving, but remain standing up 3 ft. or 4 ft. of bare rod. Holding the knife in the right hand, prick down each stake on the right side and bend over from left to right, so that it comes close down over the last round of weaving. Having bent down the number of stakes required for a start—three, four, or five, according to the width required for the border—pass them under and over each other in regular succession. In order to combine a stake with, say, five other stakes, its length must be proportionate, because they are all at equal distances from one another. Compared with a three-stake border, the five-stake one must be nearly double the thickness, because nearly double the length of rod has been put round the same size of basket. There is, however, an obvious limit to this method of bordering. Cut off the projecting ends of the stakes with the picking-knife, and lay them aside for the foot, if such be needed.

6. PUTTING IRONWORK ON SQUARE BASKET

The Rope Border. Another favourite and simple border which is used in fancy work is known as the *rope design*. To begin this, bend

No. 1 stake in front of No. 2 and behind No. 3.
No. 2 stake in front of No. 3 and behind No. 4.
No. 3 stake in front of No. 4 and behind No. 5.
No. 4 stake in front of No. 5 and behind No. 6.

Now take No. 2, the second

No. 6 and behind No. 7, bending No. 6 over it. Continue right round, and a rope border will be formed. But, note that the first four rods did not follow the rule; in fact, they could not, having nothing to go upon. Now, however, No. 4 has the last to work with and No. 1 the fourth last. Pulling them out, we combine them with the rest according to rule. All the points are sticking out to the front, and our next object must be to insert them securely into the weaving and form the whole border. Bring the point of No. 1 over the point of No. 2, and insert it into the next opening made by the curving stake beyond. By so doing, we double the curve and form the second strand of the rope. Perform the same operation with every point, and the result will give a fine rope border to the basket which we are making.

Plaited Borders. Some borders are made by plaiting four pairs of rods together in the simple manner known as the *foursome plait*—that is, one pair of rods always crossing over two [18]. This

is not great, but practice enables a

to bring out a large variety of patterns.

The Foot. To make the foot, turn the basket bottom upwards, and insert the tops cut from the stakes, after the border has been laid down alongside the stakes as if for another four sides. Weave two rounds of waling on the foot-stakes; then prick them down and border as has been described in the finishing of a basket. It wholly depends upon the thickness of foot desired what number of stakes are laid down.

Handles. The position of the handles is sometimes on the border, sometimes on the sides. In the former they are made up of rods twisted round each other and the border in a very simple way. Push the ends of two rods, at about a hand's breadth apart, in through the border and down beside a stake each. Bend over the one from left to right, and pass it through under the border on the right side of the other rod. Wind the second rod three times round the bow thus formed, and pass it through under the border; then bring it back over the border, and lap it round the bow again; repeat the action. Now bring the first rod into play, and lap it round the bow three times, performing the circle thrice in similar fashion. When finished, the tops are secured, and the handle made firm and complete. The side handle is made in similar fashion at any point on the sides or ends before the border is laid down. The basis of the *cross handle* is a hoop, worked over with rods on a rope pattern. The ends of the hoop are sharpened for driving into the weaving, each end beside a stake in the side of the basket. Bent round inside the basket to the outside, the rods are wound spirally on the hoop, and at the other end twined through the structure of the basket.

Lids. The lid of a large square basket, or hamper, if flat, is made in the same way as the bottom, with the difference that the outside sticks are

though about to make a shallow square basket, to hold the other within it tightly. The top of the lid is treated as the bottom of the shallow basket, and the sides are staked, upsetted and bordered, just the same, the

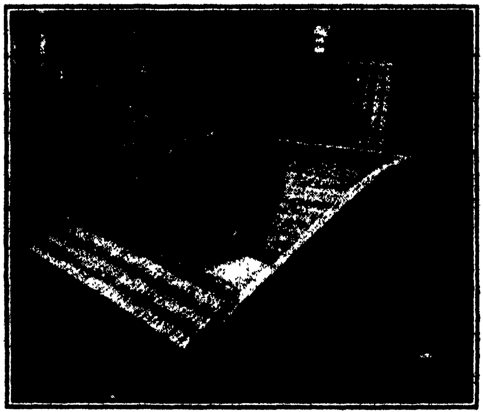
the trunk requi

Iron Fittings. It is quite possible to make baskets of the strongest and most elaborate kind with nothing but willow rods; but a stronger way of putting on the fittings is to call in the aid of iron. The hinges of the lid, for example, may be, and very often are, made of osier staples linked together and deeply thrust into the weaving. A stouter method, however, is to use a set of iron staples and an iron rod for the hinges. Again, the fastenings of the lid of the hamper, which is employed in carrying many classes of valuables, may be made of willow staples on lid and basket, secured by a padlock. But the better, safer, and more usual style of fastening is that shown in our illustration [6]. The hinged plates of brass are firmly stapled into the lid, and the tongue is brought over the staple fixed in the front of the basket. The fixing of these needs no direction.

An interesting departure in the use of iron in baskets is that known as "Parker's patent." The special feature of this device is the interweaving of a wrought-iron rod throughout the main parts of the basket, including the handles. For baskets employed in heavy work, such as coal transport or rubbish removal, the idea is very serviceable.

7. MAKING A WICKER CHAIR

Oval Baskets. In the main, the making of oval baskets, for carrying linen and other such goods, involves principles little different from those of the round basket; but the bottom is constructed in a special way. To form a base for the bottom, we require a *slath* made up of sticks and rods woven alternately over and under each other. The number and thickness of the sticks is determined by the size and quality of the basket, but four or eight tying rods are required according to the size or fineness of the basket. Working the rods in two equal divisions, the one division directed from right to left and the other from left to right, crossing and interweaving the rods with the sticks and each other, we lay a sound foundation for the bottom of the basket. After the structure has been given form, the bottom sticks are opened out and filled in by weaving, just similar to the round basket. Whether filled up by randing or slewing, the bottom is generally edged off with a pair, to give stiffness to the grip on the stakes.



8. FINISHING A BASKET FOR A MOTOR-CAR

One thing has to be noted about the sides of this and other baskets, and that is the slant which may be given in regular measure all round. On a bottom 14 in. in diameter, we may spring to a rim 22 in. or more or less in diameter. This involves a slant which must be carefully observed at all points and measured occasionally.

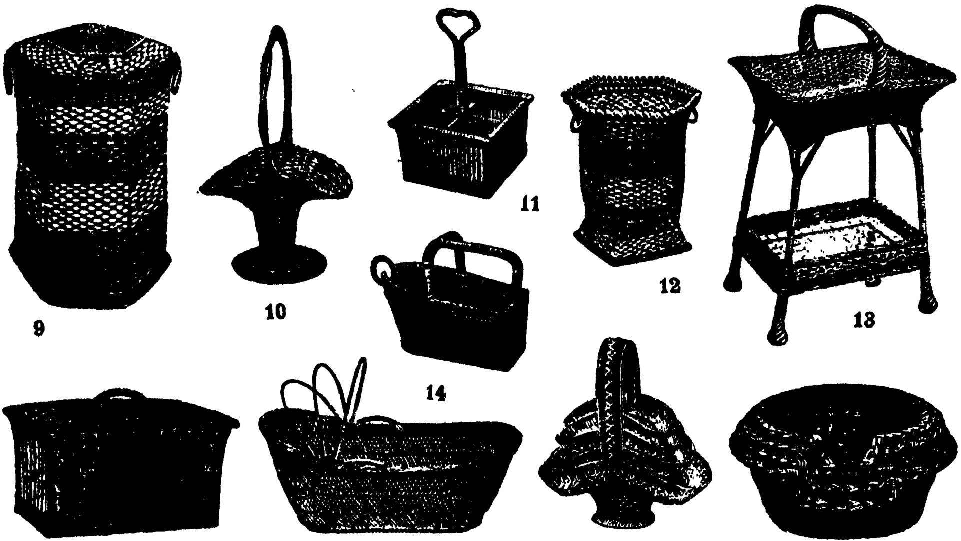
Fruit Basket with Lid. Flat, shallow baskets for holding fruit are always sure to be in demand at the fruit season, and the basket-maker usually plans to fill up odd times in making them. To anyone who has acquired the ability to make an ordinary oval or square basket, fruit baskets offer no difficulty. But sometimes the latter are made with lids which have some special characteristics. Let us attend to one of these for the short space necessary. Take a stake, mark off on it a little more than half the length of the basket, the breadth of the basket, and the half again with a margin. Make notches at the two marks, and bend the ends at right angles. This will form half a square to lie along the top rim of the basket; it is half the outside frame of the lid. Cut the ends to a slant. Prepare the other half of the frame in the same way, and see that the ends are cut so as to join neatly.

Secure the ends of the half you are going to work first with a looped rod to the breadth of the lid, and then select four or more *scallom rods*, according to the size of lid required, and twine the ends on the bow at equal distances. Shape two fairly thick sticks the length of the whole lid, and lay them ready. Now use a long weaving rod, lay the butt across the bow, with a bit to spare, and twine round the bow rod at the left side. Bring this top over the first scallom rod and round behind the first stick. At the same time fetch the butt behind the scallom rod, and bind it tightly over the first stick. Weave the two ends alternately across the whole framing, and continue with other weaving rods till the half is filled. Work on the second half of the bow, and complete the lid. See that the jointings are secure between the two halves of the bow. Various kinds of fastenings are adopted and the methods of hinging on the lid are also matters of choice. In any case, both fastenings and hinges are easily made.

Double-lid Baskets. The *double-lid* basket is a neat style of basket used for carrying drugs, glass, or other small parcels of fragile articles. No new principle is involved in the making of these baskets, though the workmanship required is finer. One thing must be specially noted—the framing is much heavier in proportion to the weaving than in ordinary baskets. In fact, the higher classes are woven with skeins. The double-lid sometimes puzzles the beginner a little, but it is little more than the two halves of the flat basket wrought and finished separately, without, of course, the strong sticks. Between the two lids a bridge is made across the basket, formed of rods neatly wound together with light osiers or skeins.

Round Cane Baskets. Various pretty round baskets may be made of cane-pith. Being more flexible, and therefore easier to work than osier, cane-pith is utilised for every kind of small basket. A simple and very useful round basket is made by crossing over two sets of canes, tying them together, weaving a round bottom with in-and-out plaiting, turning all the canes up, and continuing weaving to the top of the size designed. As a rule, the head is simply finished off with a rope or *trellis* border. For this purpose, the stakes, or radials, are left very long. We have looked at the rope border, let us glance now at the trellis. Turn down stake No. 1 behind stake No. 2, and thrust into the side of No. 3. By this method, we form a series of hoops on the top of the basket, showing a very graceful border.

Fancy Strokes. At the beginning, whenever that was, the basket-maker taught the weaver; but the worker of yarns has far outmastered his teacher, and now he can learn how to combine patterns from him. By varying the length of the crossings of the plaited yarns the clothmaker brings out fine effects, and the basket-maker has also learned the secret. Using flat stakes for the sides of baskets pretty effects are produced by making a square of alternate crossings surrounded by skeins passing two uprights at a time. Zig-zags, checks, stripes, and even figures are produced in this way. Stained canes, or osiers, give an even wider range to the artistic taste.



VARIOUS ARTICLES IN WICKER

9. Sexagon fancy soiled linen basket of wicker and rush plait **10.** Flower basket **11.** Partition basket for sauce **12.** Fancy waste-paper basket sided up with straw plait and rush plait **13.** White wicker work table **14.** Decanting basket for wine **15.** Buff picnic basket **16.** Bassinette, cross-fitched **17.** Nest of flower baskets **18.** Nest of dog baskets with plaited borders

Fancy Shapes. The rage for cheapness has spoiled somewhat the pleasure of the worker in the trade. Many of the fancy baskets which obtain a large scale are mere framings twisted, or what is most atrocious, nailed together, and woven in with fancy plaitings of straw. But the genuine article obtains a steady market if it is also tasteful. A neat workbasket can be made of light canes on a wooden framing, and with handles coming from the four corners to the centre. But we prefer the same model formed wholly of cane. It is not so easily worked, but the results are better. Cut a rod of cane-pith, measure into four equal parts, mark, notch with a picking knife at the corner points, bend so as to form a square, and bind the ends together. Select other eight canes of a size or two thinner, weave them across the frame, four one way and four the other. Into each corner fix a small upright. With skeins weave double a solid web along the whole frame. Bend up the crossing canes to form the stakes of the sides, which may be of any nice pattern the maker may fancy, the main thing to keep in view being the stability of the basket. If the pattern is to be an elaborate one, additional stakes must be put in. Taking advantage of this, we might make a fine trellis. Having thrust the added canes well into the bottom weaving, we bring them round on a level with the other stakes. First secure all with a double row of weaving; leave an open space of about one-third the height of the sides, and weave another double row. With the ends of the added stakes and the stakes of the frames we have ample material for making a close design of trellis-work of any pattern which may be fancied. Cane-pith being so flexible may be twisted to any shape without injury, if the fibres be kept flat.

Varieties of Wicker-work. The basket-maker and wicker-worker put out a large and wide variety of articles [9–18], ranging from the toy suite of furniture of the dolls'-house to the comfortable wicker armchair [7], from the baskets of Easter eggs delightful to the children to the crates carrying the parcels of the Post Office, and the bodies of motor-cars [8]. After he has learned the mysteries of randing, slewing, fitching, cross-fitching [16], staking, upsetting, and waling, the young basket-maker is on the way to a mastery of his trade which practice alone can give.

The photographs which illustrate these articles have been taken in the works of Messrs. G. W. Scott & Sons.

Figure 4 is from an engraving of a waste-paper basket made by Mr. Thomas Okey for the Society of Arts to exemplify the chief strokes used by the basket-maker.

PERCUSSION INSTRUMENTS & BELL-RINGING

Including the Drums, Cymbals, Triangle, Seraphine, Dulcitone, Castanets, Celesta and Glockenspiel, and the Art of Bell-Ringing

Continued from

By PAUL CORDER and ALGERNON ROSE

THE DRUMS

By Paul Corder

THIS group of instruments, although of comparatively small importance musically, is one which, of recent years, has filled an important place in orchestral music. With the exception of the kettle-drum, none of these instruments can be said to produce a sound of definite pitch, their use being almost entirely restricted to accentuating the rhythm. The percussion instruments most frequently met with in modern scores are these: kettle-drums, side-drum, bass drum, cymbals, triangle. These will be taken in the order mentioned above, and instructions given to enable the student to master their peculiarities. [Other instruments belonging to this group follow.]

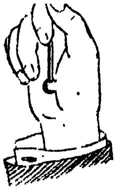
The Kettle-drums. The kettle-drums, known in France as *timballes*, in Italy as *timpani*, and in Germany as *pauken*, are the most important of the perpercussion instruments, and consist of a hemispherical copper body, with a cover made of calf-skin vellum. The vellum is secured to a ring which fits over the body of the instrument, and, by means of screws placed at equal intervals round the circumference, the vellum head may be more or less strained, thus producing notes of varying pitch. The body is supported, usually, by three sliding iron legs, the length of which may be altered and fixed with a set-screw to regulate the height of the instrument.

Two kettle-drums are usually employed in the orchestra, the larger having a compass of:

and the smaller one: 
so that the extreme notes available should lie within the octave, although these limits have been occasionally exceeded by a semitone in both directions. The larger instrument is sometimes called the F, and the smaller the B♭ drum, from the lowest note given by each.

The sticks used in playing the kettle-drums are generally made of some light wood: cherry or white beech are frequently used. They are 14 in. in length, with a diameter of $\frac{3}{16}$ in. to $\frac{3}{8}$ in., the head consisting, usually, of a disc of rubber, cloth, or piano-felt, having a diameter of $1\frac{1}{2}$ in. to 2 in. The stick should be provided with a small knob or other device at the extreme end, to prevent its slipping from the player's hand.

Tuning the Drums. The first and greatest difficulty to the student will be to acquire the art of tuning the drums to any notes required. The instruments should be placed side by side in front of the player, the small drum to the left, the larger to the right. In some orchestras this position is reversed, but the arrangement given is the more usual. In this country it seems to be the general custom for the drum-heads to be horizontal, but the method on the Continent of tilting them towards one another has a decided advantage in crossing from one instrument to the other. It will be noticed that each of the screws to be used in tuning terminates in a brass T-shaped handle, with the exception of the one on each drum that is nearest the player. These two handles, which would be in the way when playing the drum, are omitted, the two screws being turned by a separate key provided for the purpose.



HOW TO HOLD A DRUMSTICK

It must be borne in mind that by turning the screws in a direction similar to that taken by the hands of a clock the head is tightened, and, in consequence, the pitch of the drum is raised. Conversely, by turning the screws in an "anti-clockwise" direction the pitch of the note is lowered. Now, starting with the head of the larger drum quite slack, tighten all the screws successively, until each is felt to "bite" the thread of its nut; then, from this point, give each screw, say, half a turn, always including the one worked by the separate key, and omitting none. Strike the head lightly with the stick or the fingers, and, if necessary, tighten all the screws a little more until the note  is sounded. The drum must be struck near the rim, and never in the middle, where the tone is harsh and indistinct. Try whether it is in tune all round the edge, as, owing to the unequal thickness of the vellum, the intonation frequently varies. Such inequalities must be corrected by the screws nearest the faulty spots. The smaller drum may now

be tuned similarly to

Until the student has had some little experience in tuning, the notes required may be sounded on a piano or other instrument for his guidance. But later he should be able to dispense with such help. The sound of the A given by the orchestra when tuning may be of assistance in determining the pitch at first, but having tuned, as described, to F and B♭, any other notes can be found from these. For example, tune the B♭ drum up to C, tightening all the screws as before, and comparing the note with the F of the larger drum, until the interval of the perfect fifth

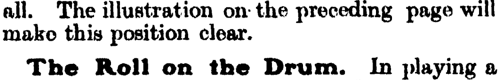
(F to C) is recognised. It is advisable in testing the note to use a light flick of the finger in preference to the drumstick, as the note is more clearly heard; moreover, there is less disturbance if the tuning takes place during the progress of a musical performance. If the drum has been tuned too sharp, it may be somewhat flattened by the pressure of the hand in the centre of the vellum. This change of tuning would be indicated in the band part by the words "Muta B♭ in C."

The student should practise tuning to various notes until perfect facility is obtained, even while the orchestra is playing in a totally extraneous key.

Many mechanical devices have been invented to abolish this tedious system of tuning, but they are so seldom seen in this country that it is not thought necessary to describe them.

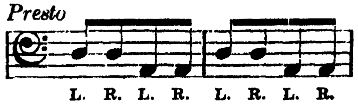
The correct position for holding the stick may now be considered. It is the same for both hands. The stick is gripped between the thumb and the side of the second joint of the forefinger, which form, as it were, a pivot on which the stick can swing. The middle finger, which is below the forefinger, should touch the stick near its extreme end, and, in conjunction with the ball of the thumb, should control its movement. The other two fingers should not touch the stick at all. The illustration on the preceding page will make this position clear.

The Roll on the Drum. In playing a roll—one of the most frequent and useful effects of the drum—the middle finger gives a flick to the end of the stick, causing the head to strike the drum, and as fast as it can be made to rebound off the drum-head this is repeated, the two hands performing this action so that the strokes alternate with one another, and are not simultaneous. For a *pianissimo* roll, this finger movement alone will be sufficient, but when more tone is required it must be supplemented by a loose movement of the wrist; the forearm should be used as little as possible, and the upper-arm not at all. The student, if unable to obtain access to the drums, may readily practise the roll with a pair of timpani sticks on the seat of an ordinary cane chair, and should not find much difficulty in acquiring the necessary skill. The roll is indicated in the music by one or other of the following signs, the meaning in each case being identical:



Care must be taken in playing single notes to let the stick bounce off the vellum as soon as the note is struck, as otherwise the tone will be destroyed; at the same time, the drum must not be permitted to sound for longer than the value of the written note, but must be muffled with the finger-tips or the hand.

As a general rule, the drum on the right hand is played by the right hand, and that on the left by the left hand; but exceptions to this are numerous. Several notes in quick succession on one drum would be played with the two hands alternately, and in certain cases the hands require to cross:

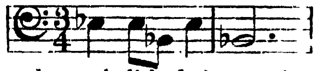


Instances of this cross beat are numerous.

In former times, when it was customary to give the kettle-drums only the tonic and dominant of the key to play—*i.e.*, the first and fifth, the notes were always written as C and G, whatever the sounds to be produced, the actual notes being indicated at the beginning of the movement; thus

Timpani in E♭. B♭.

would be played



This custom has now been abolished since tuning other than the tonic and dominant has been required.

Frequently three or even four drums are employed in the orchestra, and even if not actually required together, the use of a third obviates the necessity for so many changes of tuning.

In playing in an orchestra the student will have to accustom himself to the counting of many bars' rest. This is not among the least of his difficulties, especially if it is necessary to alter the tuning of the drums in the meantime. Nothing but practice can give facility in this matter, practice until the process of counting becomes almost automatic. It is of great assistance in finding one's way during a long rest if the band part is supplied with cues giving a prominent phrase of another instrument; also, pauses and changes of time should be noted, as these form landmarks, as it were, which enable the student to keep his place in the music. The foregoing remarks apply equally to the other percussion instruments now about to be considered.

The Side-drum. The side, or military drum consists of a wooden or metal cylinder with a vellum head at each end, tightened sometimes by means of screws, sometimes by cords and leather braces. In the orchestra it is fixed in front of the player in an upright or somewhat inclined position, the top head alone being struck. The lower head has several catgut cords stretched across it, called *snares*, which rattle against the skin and give the drum its peculiar, characteristic rasping tone.

The sticks are of hard wood, and are held in this way. The right hand grasps the stick near the end with all the fingers clasped round it, so that the knob shall strike the drum in the middle; the left hand is held with the palm turned towards the player, the stick clasped near the end by the thumb and forefinger, and then passing between the middle and third fingers.

To play a roll on the side-drum is by no means easy, and will require considerable practice to enable the student to master it. It differs from the roll on the kettle-drums in that two notes are struck with the left hand and two with the right, alternately. In making a crescendo during a roll, begin *pianissimo* near the hoop and advance nearer the middle as the tone increases, reversing the process for a *diminuendo.* The same methods of indicating a roll are used as described for the kettle-drum.

It is sometimes required in funeral marches and pieces of similar character to muffle the drum; this is accomplished by inserting a piece of cloth between the snares and the vellum, which prevents their vibrating; or a still more muffled effect is produced by enclosing the whole drum in a bag and playing through the cloth. The Italian word *coperti* is used to indicate muffling.

Music for the side drum is generally written in the treble clef; the exact note used is quite immaterial, as the drum should be of indefinite pitch.

The Bass Drum. The usual form of this instrument, that of a short cylinder of large diameter with vellum heads, will be familiar to everybody, and although there is a variety frequently met with in orchestras which resembles a big tambourine, only one side being covered with skin, the manner of playing is the same in either case. The drum is mounted on a stand or suspended from a frame, and except in military bands one side only is used. Generally only one stick is employed, the head terminating in a large knob covered with wash-leather, or sometimes made entirely of piano-felt. A smaller knob is not infrequently furnished at the opposite end of the stick, and in playing a roll the stick is held in the middle, and by a rotary movement of the arm each knob is made to strike the drum-head alternately. Another (and in many cases preferable) method of playing a roll is by means of a pair of timpani sticks held in the manner described for the kettle-drums, the only difficulty being that the drum-head is vertical instead of horizontal, as with the timpani.

In playing single notes the stick should be held loosely near the end, and should not move at right angles to the drum-head, but should rather sweep past it, striking the blow in passing. When a short note is indicated the vibration of the vellum must be stopped with the hand.

Music for the bass drum is written in the bass clef; the actual note used is, of course, quite immaterial, as the sound produced should be of indefinite pitch.

THE CYMBALS

The cymbals consist of circular plates of hard brass, which are held, one in each hand, by leather thongs fastened through a hole in the centre of each.

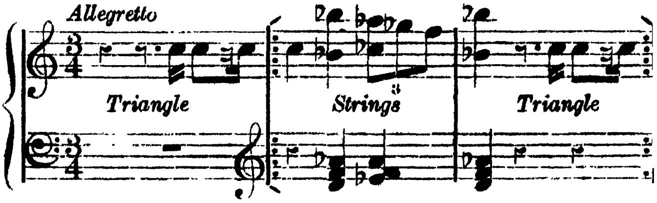
There are several effects to be obtained from this instrument, the most usual being the striking of the two together. This should be done with a sweeping movement of the cymbals past one another in order to obtain the best possible tone. Begin the stroke with the right hand somewhat higher than the left, and finish it with the left hand above the right (or vice versâ). Practise this stroke with varying strength from *pianissimo* to *fortissimo.*

Very frequently the bass drum and cymbal parts are written together, one player being supposed to manage the two instruments. In this case one cymbal is bolted firmly to the drum, the player wielding the other with his left hand, while the right is occupied with the drum-stick. This practice has many objections, and wherever possible the cymbals should be played by a separate player.

In playing a roll on the cymbals, unless otherwise indicated, the two cymbals are held close to one another, and the right hand made to rock quickly backwards and forwards so that alternate sides of the right-hand cymbal strike that in the left hand, which is held stationary. It is not easy to obtain much tone by this method, and a roll is frequently indicated to be played "*with drumsticks.*" In this case one cymbal should be suspended by its leather handle, and a roll executed on it near the rim with a pair of timpani sticks, in the manner described for the kettle-drum. The tone thus produced is peculiarly penetrating and sinister. Single strokes with a drumstick are sometimes required, for which purpose the bass-drum stick is to be preferred.

THE TRIANGLE

The triangle consists of a rod of steel bent to the shape of an equilateral triangle, the ends of which, however, do not meet. It is suspended from one of its angles, and is struck with a steel rod, producing a clear, penetrating note of indefinite pitch. Its employment in the orchestra is very limited, as it has scarcely any range of tone. Its chief use is to mark the rhythm in dance music. The only instance the writer can recall of the use of the triangle as a solo instrument is in this passage from Liszt's Piano Concerto:



The triangle notes, although written as C, do not, of course, sound so.

A shake or roll is sometimes required, and is played by rattling the striker across an angle of the instrument, it being necessary to guard against the tendency of the triangle to revolve meanwhile if, as is usual, it is suspended by a piece of string or gut.

Triangles are made of various sizes, but large ones are unsuitable to the concert-room. The smaller the instrument the shriller its note.

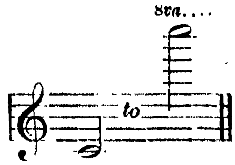
CELESTA & GLOCKENSPIEL

By Paul Corder

These two instruments, although dissimilar in many respects, are taken together on account of the subordinate position they occupy among musical instruments. Although they have a tolerably extensive compass, their use at the present time is solely confined to a few orchestral compositions, no solos having been written for either instrument by any composer of note. Nor is it difficult to understand why this is so; although the tone of the celesta is quite the most pure and beautiful of any instrument, yet it lacks variety and means of expression. *Fortissimo* and *pianissimo* have for the celesta hardly any meaning, and the clear, bell-like tone becomes monotonously irritating to the ear after a short time. Nevertheless, in its proper place in the orchestra the celesta is unequalled, and one need only refer to the third movement of Tschaikowski's charming "Casse-Noisette Suite" to call to mind the delicious effect of one of these instruments used with due discretion.

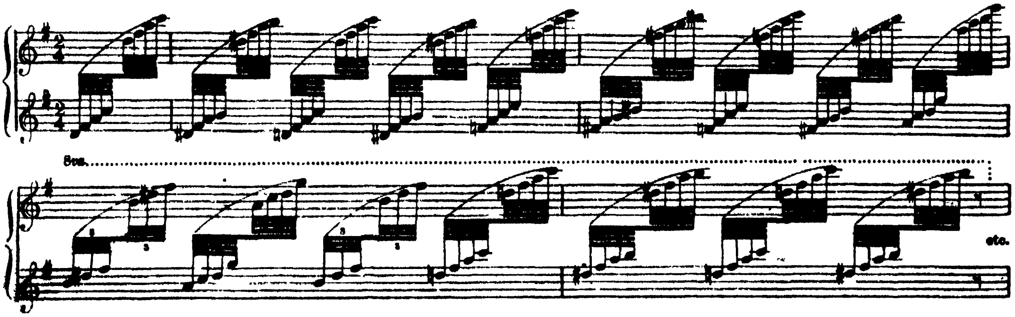
The Celesta. The celesta, as made by M. Mustel et Fils, of Paris, has the appearance of a small pianoforte, being provided with a keyboard similar to that instrument, but of less compass. The interior mechanism consists of a series of metal slabs with resonators, which are struck by hammers actuated by the keys. It will be assumed that the student who is desirous of playing this instrument knows something of the pianoforte [see Pianoforte, page 1210], in which case we need only point out in what respects the celesta differs from the superior instrument.

Its compass is generally considered to be as shown below, with all the intermediate semitones, but the makers have lately been extending this, and have recently produced instruments having several notes below middle C. But these low notes seem to be very poor in quality and weak in intonation; certainly the higher part of the instrument is the more effective.



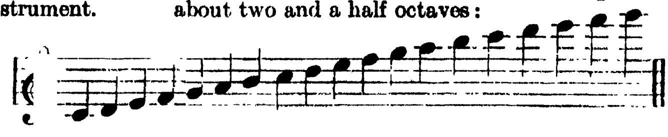
In order to avoid a multitude of ledger lines, composers sometimes write an octave lower than the part is to sound; but this custom is by no means uniform, and the executant will often have to use his discretion in deciding what are the composer's intentions.

The very limited powers of tone variation possessed by the celesta have already been mentioned, and although, with care, a good *piano* can be obtained, anything like a *forte* is out of the question. Moreover, in some instruments, if not in all, an appreciable amount of force is necessary to make the note "speak" at all; an exceedingly light "weight touch" such as would produce a perfect *pianissimo* on the pianoforte seems insufficient to actuate the mechanism of the celesta, and may result in no sound at all. For this reason evenness in arpeggios should be carefully practised as softly as possible. The following passage from the "Casse-Noisette Suite," already referred to, will make a capital study.



The Glockenspiel. The glockenspiel, or carillon, is an instrument of very different appearance, although it is more akin to the celesta than might be supposed at first sight. It consists, essentially, of a series of steel bars, which are struck with a light wooden hammer; but, unlike the celesta, these are struck by hand, the steel bars being suspended in a frame. In England this is generally a brass "lyre" shaped head supported on a stand; strings are stretched horizontally across this, on which the steel notes are hung, one above the other. There is another variety of this instrument, in which the steel bars are laid horizontally in a frame, but this is not often met with.

Usually, only as many notes as are wanted at the time are brought into use, extra notes being hung up as required. The complete compass is about two and a half octaves:



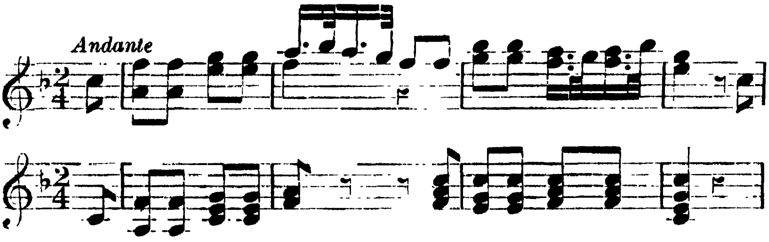
including all the intermediate semitones. The actual sounds produced are an octave higher than given, and are sometimes written so by composers. As these notes are sold separately, the student should test them before buying, for they vary considerably in purity of tone.

The tone of this instrument is much brighter and more penetrating than that of the celesta, and very quickly wearies the listener. Its range of tone is likewise exceedingly limited, but in this case it is uniformly loud, a *pianissimo* being an impossibility; or, more strictly speaking, its tone is so penetrating as to predominate invariably over all other instruments.

A difficulty to one not accustomed to these instruments is to remember that the notes in use do not necessarily represent consecutive degrees of the scale, nor are they always of the same set, but vary according to circumstances. However, each is clearly marked with its name, and by keeping the highest at the top of the frame, descending according to pitch, there is no occasion for any confusion.

The manner of hitting the notes is quite simple; a smart tap with the hammer, which must be allowed to rebound instantly, is all that is required, but it may be advisable to stop the notes from vibrating too long by means of the fingers of the other hand. Sometimes two hammers are used, one in either hand, and certainly the second one is a great help in executing rapid passages.

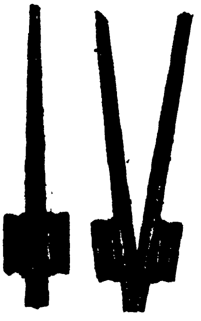
The part written for the glockenspiel by Mozart in the "Magic Flute," beginning is impossible on the instrument just described, and is intended to be played on a glockenspiel furnished with a keyboard. With a little alteration the passage could be played on the celesta, for which instrument, had Mozart lived a century later, he would most certainly have written it. In Handel's oratorio "Saul" there is a somewhat similar passage, which is written as though for a transposing instrument in G—that is, a fourth lower than it is meant to sound. [For a more detailed explanation of transposing instruments see the HORN.]



In conclusion, half an hour's practice at any of these instruments will do more for the intelligent student than pages of written description.

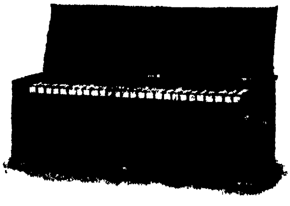
THE SERAPHINE

In an orchestra or in a church, in conjunction with the organ, the seraphine represents in tone the effect of a carillon. Whereas, in the glockenspiel, small steel bars are substituted for bells, in the seraphine—used in certain modern orchestras—thin steel reeds, beautifully voiced, acted upon by coiled springs, are connected with a keyboard. Rapid articulation is thus facilitated. Moreover, the tone is increased or diminished in force by wind pressure, the feet of the player working a pair of small bellows as in a harmonium. Although the notation to be played may appear simple, so penetrating is the tone of the instrument that the slightest mistake is very noticeable. A performer entrusted with such a part must, therefore, be either a pianist or an organist. For detailed exercises, appropriate to seraphine playing, the student is referred to studies written for the organ or pianoforte.



Shut Open
WOODEN CLAPPERS

DULCITONE



DULCITONE [Machell]

Instead of steel rods, this ingenious instrument contains rows of tuning forks struck by felt-covered hammers, damped by felted levers. After the instrument once leaves the maker, no tuning is therefore required. The compass is from three and a half to five octaves, and the weight is from 25 lb. The dulcitone has been used with marked success as a substitute in the orchestra for distant bells, or in conjunction with the church organ for echo effects. In ballet music, also, it has been heard with advantage. In quality, the tone is pure, sweet, and carries well. As the price is moderate and the instrument takes up but small space, it serves as an excellent substitute in house boats, yachts, and elsewhere if room is a consideration.

CASTANETS & TAMBOURINES

In the modern ballet orchestra, indispensable features of gipsy, Spanish, or Neapolitan dance music are parts for these percussion instruments. When, in so-called programme music, the composer endeavours to portray unusually realistic effects, the side-drummer has to be provided with a number of strange contrivances. It is to him that the manipulation of such accessories is allotted, especially in open-air band performances. In pieces descriptive of a hunt, etc., he needs a pair of wooden clappers to imitate the sounds of a whip. The orchestral whip costs about 6s.

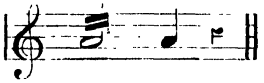
Haydn, Romberg, Mendelssohn, and other masters in their burlesque or toy symphonies, make use, further, of the sounds of various bird-calls and the pop-gun. The latter, in descriptive military band arrangements, occasionally necessitates the side-drummer being provided with a band pop-gun. This costs about 6s., and its noise is sometimes effective.

POP-GUN [Mahillon]

Tambourines. The chief of the side-drummer's accessories are the tambourine and castanets. For military bands, the tambourine is 15 in. in diameter, and costs about 18s. The orchestral model is slightly smaller. "Tambour," or drum, gave this instrument its name. It consists of a single drum-head, or parchment skin, stretched over a circular rim. The depth of the latter reinforces the sound. Small rods are fitted in the rim. To tighten or slacken the vibrating surface, screw the fly-nuts up or down. Cut out in the rim are a number of slots. In these slots miniature cymbals are arranged loosely in pairs. These impart to the tone much of its distinctive effect.

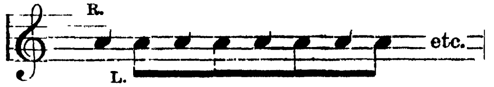
MILITARY TAMBOURINE

Tambourine music as an orchestral accompaniment to the tarantella or any Oriental dance, is written in the treble clef, usually on A, second space, being marked in the side-drum part. Although this instrument is a species of drum, it is not hit with a stick. Both hands of the player are required for its manipulation. It is capable of a variety of effects. When simply struck by the hand by a body of dancers, the peculiar noise it gives is most distinctive. If it be played by a single performer, one hand usually causes it to vibrate, so that the small cymbals jingle, whilst it is struck by, or strikes, the fist or tips of the fingers of the other hand. Berlioz has made considerable use of tambourine effects. A favourite direction of his was to get the curious tremolo, or roll, which is obtained by rubbing the tambourine-head with one of the fingers of the hand, not holding it. In that case, the noises of the small bells in the rim are chiefly audible. Such a roll is indicated as here shown. It is usually very short, because the finger rubbing the parchment causes the sound to cease as the digit approaches the margin of the rim. In music portraying a masquerade, or other extravaganza, a weird rumbling is caused by rubbing the vellum with the full strength of the thumb. By spinning the instrument on the finger-tips, expert players get other varieties of sound from the tambourine.

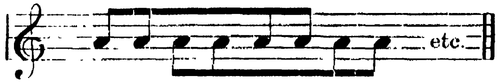


Castanets. In ballet music, when Spanish or Oriental dances are introduced, inseparable from the tambourine are the castanets. "Castaneta" is the Spanish for chestnuts. Ever since the Moors introduced into the South of Europe certain characteristic dances it has been the custom for the performers to attach to each hand small cups of hard wood or ivory, joined together by a string, and shaped like the two sides of a chestnut. If these adjuncts are not available, the clicking effects they produce are imitated by the dancers drawing the fingers quickly, from the point to the ball of each thumb. Most Spaniards are experts in this accomplishment, but in a ballet, if the dancers use castanets, they are fitted to the fingers. One little clapper is fastened to the thumb, the other is attached to the middle finger. To emphasise the rhythm of the dance, the two are then struck together.

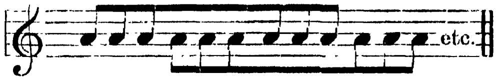
But there is a vast difference between merely clicking the castanets and playing them expertly. Accomplished performers are able to get a neat roll on them of several bars' duration. To do this requires careful practice. The student who desires to be able to articulate distinctly the different rhythms indicated in the ballets of Bizet, Delibes, to say nothing of those of Wenzel, Jacobi, or Byng, should begin by single-stroke exercises with alternate hands.



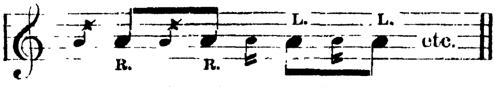
Here the object is to make each beat with the utmost regularity, and the student is advised to practise with the metronome in slow time at first, and increase the speed gradually until the semblance of a roll is obtained. Having acquired facility to make a single sound with each hand, try double sounds in the same way.



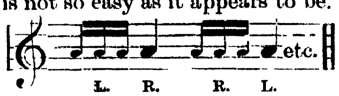
The next problem is to get distinct triplets by the hand, without any break or hesitation in the sequence of the sounds, so that each stroke should be of equal force.



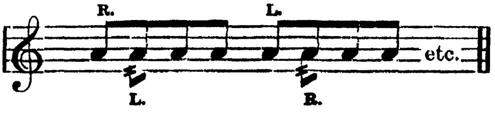
Grace-notes. As the castanets are embellishments in themselves to the effect of the dance, their performance is pleasantly varied by making short clicks or grace-notes mingle with those which are more emphasised. First, endeavour to produce a short click preceding a loud one, so that the right hand gives two postman's "rat-tats," and the left hand echoes those sounds without break.



The student should next endeavour to make with one hand a quick triplet softly and finish it by a loud stroke with the other hand. This is not so easy as it appears to be.



In side-drum playing, three grace-notes together are known as a "full drag." It must not be forgotten that in dancing the time-stroke usually falls when the point of the toe touches the ground, and that stroke should be emphasised. But during turning movements, pirouettes, or bendings, the castanets are particularly effective when they execute a number of short grace-notes together. These are, in a solo dance, inserted according to the fancy of the artist. But if they are to be a true embellishment, the castanets should be practised apart from the dance. We give in conclusion, one of the most ordinary examples of the insertion of such grace-notes.



Here it will be observed that the right and left hands alternately make four clicks in strict time. But on the second beat in each quadruplet the opposite hand inserts three or more short notes to embellish the rhythm. In the seguidilla and other lively dances, the castanet-player who can do this neatly finds that the time spent in study is well rewarded.

But when castanet music appears in a side-drummer's part he has no time, as a rule, to fit the apparatus to his fingers. Therefore, the orchestral or military performer provides himself with a pair of castanets attached to a handle about 1 ft. long. Between the two little cups is the stationary bowl of a wooden spoon, so that, when the handle is shaken, the castanets strike against this bowl. The player can thus at any moment insert castanet effects without difficulty. Sometimes in military bands a pair of castanets, held open by light springs, is attached to the hoop of the side-drum, and is manipulated by the drumstick. Orchestral castanets cost about 4s. The more familiar nigger minstrels' "bones" are but enlarged editions of the classical castanet, which goes back to the days of Babylonia and Assyria.

BELL-RINGING

Between the music of Art and that of Nature, bells are regarded as the connecting link. Being of fixed tone, they have been occasionally employed for impressive orchestral effects by Auber, Rossini, Donizetti, Meyerbeer, Sullivan, Wagner, and other great composers. Yet, in an artistic sense, bells are incapable of musical use in their truest form, since their full sounds can only be elicited when they are swung and hit by a clapper. But this precludes timing the exact moment of striking as well as the precise degree of force for each blow. It is, however, the irregular and formless character of the tones produced even by the best change-ringers which imparts that wild mystery or uncertainty to the sound of bells so attractive in the open country.

Of bell-ringing, the chief kinds are handbell-ringing, steeple-ringing, and tower-carillons.

Handbells. Nearly every church possessing a peal of bells keeps a miniature set for training beginners before they are allowed into the steeple. Though somewhat similar in appearance to the railway handbell, the tone is differently controlled. Instead of the clapper swinging loosely, it is supported by springs. These keep the tongue from touching the bell-lip when held horizontally. Yet, when the bell is required to be struck, the springs offer the least possible resistance. Moreover, the tongue, instead of being of metal, is of thick felt weighted to give the necessary force. Instead of being harsh, the tone produced by this means is sonorous and sweet, allowing the harmonics to be heard pleasantly. A peal of eight handbells, properly tuned, can be procured from any bell-founder for from £4 to £5. With these small editions of the large steeple-bells, the intricacies of ringing can be learnt without annoyance to a neighbourhood. For ordinary changes, five bells suffice. Few towers contain more than this number.

The students should seat themselves in a semicircle, so that each can see the other without having to turn round. On the extreme right of the semicircle is seated the first treble—generally the youngest performer—he having the smallest bell. At the extreme left point sits the physically strongest man with the largest bell, known as the bass. In the centre of the semicircle is the alto. In advance of him, on the right, is the second treble, and on the left of the alto is the tenor In front is the conductor. Instruction starts by each student being taught how to sound his bell properly.

Correct Position of Hand and Bell. Grasp the bell by the handle. Hold it downwards to represent the position of the bell as it hangs in the steeple. The leather handle, here, is flat, and the clapper is so hinged that it will only swing towards the flat sides of the handle. If held flat-side uppermost and waved from right to left, or left to right, it will not strike. Only upward or downward motions cause it to sound. In grasping the handle the thumb, pointing downwards, should press the brass rivet in the flat side towards the body of the ringer. Turn the back of the hand to the left, so that the fingers are round the flat side of the handle away from the body. Now, sloping the handle slightly downwards, the clapper will fall by its own weight opposite the side it is to strike. The spring prevents the tongue touching the lip of the bell.

The "ring" is given by turning the hand half round to the right. To ensure the strike, all that is needed is a slight impetus from the wrist. The first motion is to get a blow with the bell upwards. Raise the bell towards the shoulder, giving a slight jerk to represent a "hand stroke" in the steeple. The next motion is downwards towards the knee, to represent the "back stroke."

Rounds. The most common use to which a peal is put is that of ringing "rounds." On the Continent, besides pulling bells singly or clashing them together, campanology is unknown, despite the praises Schiller and many other foreign poets have lavished on the ringing of bells. In Great Britain, however, if there are five bells, they are tuned diatonically, and range, in position of rounds, numerically from the smallest to the biggest. The first treble, therefore, is "No. 1," the second treble "No. 2," the alto "3," the tenor "4" and the bass "5." In round-ringing the art is for each bell to strike with the utmost regularity. The custom is for each ringer to start off with a hand stroke, continuing without pause, each with a back stroke. When changing, in the third round, from "back" to "hand," there is a slight pause, as if, after counting five, came the figure "0." Two rounds are then played without break, the completion of the whole "pull" being marked by a second pause, and so on with a rest after every two rounds or whole pull. Consequently, if the ringing is in four-four time, the effect, at the beginning, puts the accent on the "lead," given by the first treble. The fifth bell, being the bass, the accent on the next bar is transferred to the lowest note. This is immediately followed, without break of time, by the three upper bells, so the third bar gets its accent from the tenor. This is followed by the bass bell to complete the back stroke. On the third beat of the bar there is a pause, and the first treble, beginning on the fourth of the bar, the accent on the fifth bar is given by the second treble. The smallest bell thus starts the sixth bar. But, as a back stroke is given, the tone is different in character to when that bell started off with the hand stroke.

The next bar is begun by the bass to finish the back stroke, and complete the whole pull. In the sixth bar, a rest thus occurs on the second beat. So the two treble bells mark the "three"—"four," and the accent on the seventh bar is made by the alto, and on the eighth bar by the second treble with the back stroke. Although only five notes are repeated in the same sequence, owing to the different accents and strokes considerable variety is accomplished in good round-ringing. [Ex. 1.]

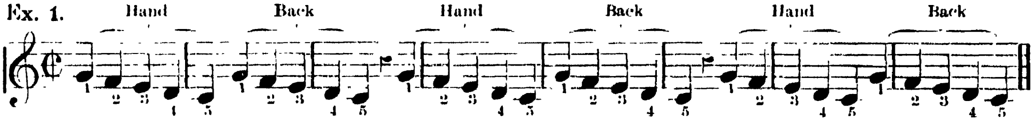
By altering four-four into three-four time, on the word "Go" from the conductor treble leads with a hand stroke as before. But the tenor, as his bell is fourth, puts the accent on the second bar. The fifth and first bells having struck, the accent on the third bar is transferred to the second treble, and the bass emphasises the first beat of the fourth bar. Pause on the second beat. The third beat is thus given by the "lead," and the fifth bar has the hand-stroke accent from the second treble, while the same accent by the bass starts the sixth bar, the alto emphasising the seventh. On the first beat of the eighth bar there is a pause; on the ninth, the accent is given by the alto with a hand stroke, the treble starting the tenth with a back stroke, the eleventh bar being accented in the same way by the tenor. [Ex. 2.]

Change-ringing. Bells are said to be in "changes" when struck in any other order than their normal numerical sequence. To ring a change implies the constant variation of the order in which the bell strikes. Alteration must be made according to rule with any given number of bells, so that they work observing the correct formula. If there are four bells, 24 changes is the limit, and the time occupied is one minute. If there are five, 120 changes is the number, these taking five minutes. With six bells there are 720 changes, occupying half an hour. With seven, upwards of 5,000 take three hours This is called a "peal." Shorter changes may be designated a "flourish" or "touch." With eight, upwards of 40,000 changes require a day and four hours. Nine bells give more than 360,000 changes, occupying ten days and twelve hours. When we come to twelve bells, the changes run into millions. In an early stage of the art, therefore, five bells with 120 changes suffice for any student. No change is complete until every variation of which the peal is capable is produced. The bells are then brought back into rounds. Like a ship, a bell is of feminine gender. She is never referred to by a bellringer as "it," but always as "she" or "her."

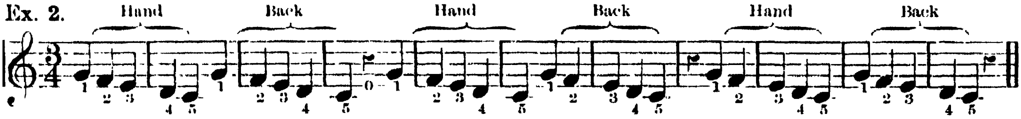
"Dodging." After rounds, the student must understand how to "dodge," either with the bell before or after him. If he has treble, and is told to "dodge," on the word "Go" he leads off with a round, first with a hand stroke and then a back stroke. Then comes a pause for No. 2 to ring first, No. 1 taking his proper place with the back-stroke round. He strikes second in the sequence which follows, and first again on the word "Round" from the conductor. If he is put to the third bell and is told to "dodge with second," on the word "Go," a hand and back stroke round being rung, in the third sequence he will strike in No. 2's place, the latter following him In the fourth sequence, he strikes in his own place, dodging again in the fifth sequence. On "Round" being called, he returns to his normal order.

A bell goes "up" when she strikes in a different numerical position, moving on from treble to tenor at each change. Her course is termed "going up" if, after leading off first in round, she "dodges" to second in the next sequence, dodging again, with the bell striking after her, to the third and fourth places

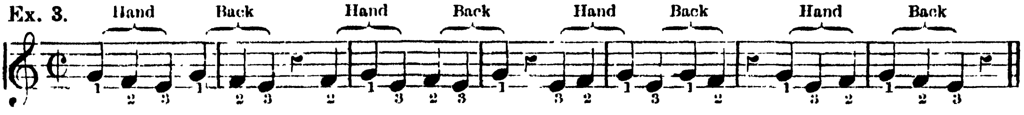
Ex. 1.



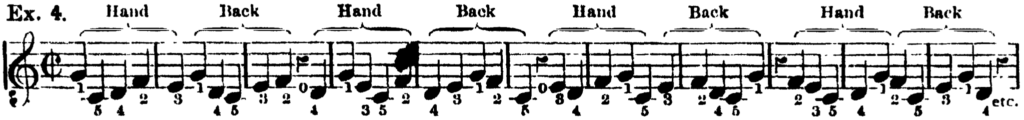
Ex. 2.



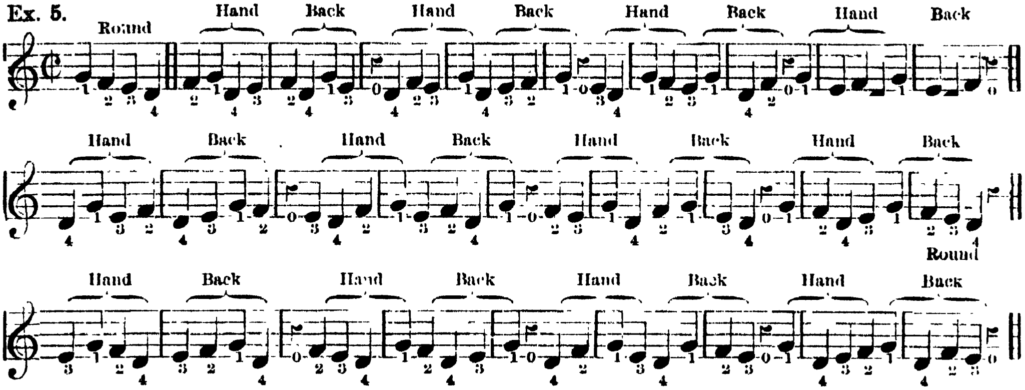
Ex. 3.



Ex. 4.



Ex. 5.



in the next two changes. On the other hand, her course is called "going down" if she alters her position from behind to the front. In the steeple, the expression refers to holding "up" the bell herself, when she must be rung slower to allow the others to strike before her. Likewise, if she is returning to "lead," she must be struck more quickly, or "rung lower." In other words, she then goes "down."

"Hunting." Hunting is carried out in two ways—"hunting up" and "hunting down." The first means striking after the bell last pulled, and is applicable to any number of bells. If three are being rung, and the student is first treble, on the word "Go" second treble will strike after him. In the first change, he must, therefore, pull after No. 2. The sequence thus is 2 1 3. Keeping his eye on No. 3, No. 1 will next strike after her. The order will then be 2 3 1. This brings No. 1 behind. On arriving in that position, the rule is to strike in the same place in the next change. So the sequence following becomes 3 2 1. Having "hunted up," No. 1 must now "hunt down." To do this, he has to look for the bell which strikes first of the other two. This is No. 3. Ringing after her, the sequence becomes 3 1 2. He is thus brought into No. 2's place. In the next change, he leads. The sequence is 1 3 2. As the rule, on returning to "lead," is to strike twice, in the next change the order of the bells is normal. They are, therefore, brought back to rounds, having performed the full six changes possible by three bells. [Ex 3.]

Hunting with Five Bells. Instead of three handbells, try five. If the student has first treble, and watches his four companions, he will soon get into the way of sounding his bell at the correct moment. At the first change he will strike into No. 2's place by ringing after the bell which followed him. If the sequence was 1 4 5 3 2, it will now be 4 1 3 5 2. Therefore, No. 1 bell will now be "below," and No. 3 "above" him. He must observe the latter to note which one follows him. Next time, he must "pull" after that one. In other words, he changes his sound-place with No. 3. The sequence rung becomes 4 3 1 2 5. Striking now in the centre place, he will have two bells "below," and two "above." Keeping an eye on the latter, he strikes his next blow after the bell which follows him. The sequence is, thus, 3 4 2 1 5. Having taken No. 4's place, there are three bells "below," so that he has only one to note. Striking after this next time, the change becomes 3 2 4 5 1. This makes his first stroke "behind." Having four bells "below," he must strike after the last of them. This will be No. 1's ultimate stroke "behind." Reversing the process, he will hunt down the other four bells. He lets the last number he pulled after pass him, so that he descends into No. 4's place. Striking after the last of the three below him, he next rings in No. 3's place, and, in due course, No. 2's, till he gets back to "lead." He will then strike again in the next sequence, and continue to hunt up and down till rounds are called.

The Course Method. Many ringers consider the "course" plan easier for hunting down than that described. All the student has now to remark is the bell which he "turns from behind," or that after which he has next to ring. When he has struck after her his first blow behind, she becomes his "course" down to lead. Supposing the student is No 2, and the sequence is 1 5 4 2 3. In hunting up, No. 2 turns No. 3 "from behind." So the first blow No. 2 strikes behind makes the sequence 1 4 5 3 2. According to rule, in the next half round No. 2 must strike behind again. But the ringer watches No. 3, that bell having moved down one, giving the sequence 4 1 3 5 2. The fifth, therefore, comes between 2 and 3. In the next change, as No. 1 is hunting up, she will intervene. No matter what bell follows No. 3, No. 2 follows that bell. The sequence thus becomes 4 3 1 2 5. In the next change, she moves down one into No. 3's place, No. 3 now being at "lead," the sequence making 3 4 2 1 5. As No. 3 has to give a second blow in the same place, No. 2 now gets close to her "course." So the sequence is 3 2 4 5 1. In the next change, therefore, No. 2 gives the first blow. The result of this hunting down by "course" method sounds as in Ex. 4.

Place-making. When a bell arrives "behind" or at "lead" in hunting, we have seen that she must strike two blows in each successive half round, so that she "lies a whole pull" in the same position. Yet, if this lying a whole pull were made uniformly, the possibilities of variation could not be fully developed. It is necessary, therefore, for other bells sometimes to "make a place" in the same way in one of the inner positions by striking two blows in succession at the same point. Thus, if No. 5 follows No. 1 in the first half-pull, and is cautioned to "make a place" in the second half-pull, she will again follow lead. Hence, she also will lie a whole pull next to treble. Meanwhile, No. 4 has been told to make place at No. 3. Thus, while No. 5 goes down to lead, No. 4 makes a second blow in No. 3's place, lying a whole pull in that position, as will here be seen:

1 5 3 4 2
1 5 4 3 2
5 1 4 2 3
5 4 1 3 2

To make all the alterations of which four bells are capable necessitates a knowledge of further rules. Here the changes are divided into three sets of eight each. On the word "Go" rounds are rung till the ringers get steady. Bells 1 and 3 then start hunting up, whilst 2 and 4 proceed to hunt down. Each bell lies a whole pull on arriving at "lead" or "behind." By "plain hunting," the eight changes produced are these:

2 1 4 3
2 4 1 3
4 2 3 1
4 3 2 1
3 4 1 2
3 1 4 2
1 3 2 4
1 3 4 2

The bottom line introduces a new rule. If the plain hunting were continued, No. 4, on arriving behind, would strike twice, and No. 3 proceed to third place, while No. 2 would descend to second place. With that method, however, the result would be a normal round. This should not occur until the whole change is rung. To produce the twenty-four variations, the rule is that "the bell treble takes from 'lead,' makes second place and leads again, the other bells dodging at back stroke-lead of treble." The ringing is thus given a fresh lease of plain hunting:

3 1 2 4
3 2 1 4
2 3 4 1
2 4 3 1
4 2 1 3
4 1 2 3
1 4 3 2
1 4 2 3

Here we see Nos. 3 and 1 are hunting up, while Nos. 2 and 4 hunt down, each bell striking twice on arriving at lead, or behind, except in the back stroke of the last pull, where the bell treble takes from lead, makes second place, and leads again, the others meanwhile dodging at the back stroke lead of treble. Consequently, Nos. 4 and 1 now hunt up, while Nos. 3 and 2 hunt down, until the change is completed thus:

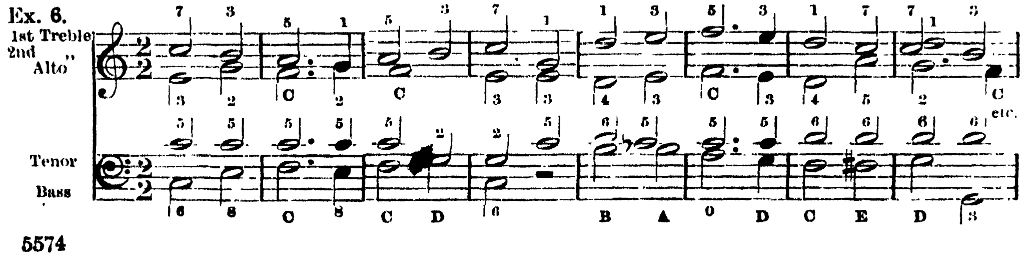
4 1 3 2
4 3 1 2
3 4 2 1
3 2 4 1
2 3 1 4
2 1 3 4
1 2 4 3
1 2 3 4

The students should now try Ex. 5.

Practising with Two Bells. The foregoing changes can be learnt by two players with handbells facing each other. One student should take 1 and 3, the other working 2 and 4. Although, in the steeple, the vibrations continue, when practising with miniatures the tone should be damped. For this purpose, double up a blanket, or thick rug, and spread it over a table between the players. Each bell is then taken up and replaced on every stroke so that no two sound together. If this is done in correct time, the effect will be *legato*. Should the damping be premature the sounds will be *staccato*. The same students can work a peal of eight bells by playing two with each hand. If attention is confined to change-ringing endless variations can be studied. Yet, however fascinating this may be in a steeple, it is not so entertaining to the uninitiated home circle. It is well, therefore, to practise diatonic melodies within the compass of one octave, as the eight bells generally represent the scale. Such exercises are useful discipline in keeping correct time. Handbell ringing by five performers has been made charmingly effective throughout a compass of five octaves including sharps and flats, different bells being used for the sharps to those for the flats. This accuracy in tuning entails 36 bells for the diatonic notes and as many more for the enharmonic semitones. Thus, each player may have 15 bells to handle. Quintets of players, after careful study together, have obtained remunerative engagements and been favourably criticised by eminent musicians.

The student who aspires to be a member of such a company must be prepared to practise unremittingly. Sometimes, the first and second trebles are taken by ladies; men manage better the larger bells. Five performers can play almost any music written after it has been arranged by a ringer possessing a knowledge of

Ex. 6.



harmony and composition. This is not so if there are only four performers. The rapid work in the upper voice is often more than one ringer can accomplish satisfactorily.

The Table. The student must be a good timist. Experience shows that the dimensions of a handbell table are most convenient when it is 16 ft. long by 7 ft. wide. To a depth of 3½ ft. from the front, the left end is reserved for the bass player's bells. At the far right end of the table towards the front (where the audience would be) is the place of the first treble, with 3½ ft. space before him for the smaller instruments. The long side, beyond the portion reserved for the bass, is divided with the second treble on the right, the alto on his left, and the tenor on the left of the alto, together with 3½ ft. in front of each of them for the bells most frequently required. That area of the table beyond these five divisions is used for depositing bells not wanted during the performance of a piece. If, for instance, the melody is in G, the C♭ bells are not likely to be required. As all pieces must be memorised before a public performance, players soon know the bells they need for any item.

Stand to play, and do not waste energy by flourishing about a bell except when a long, sustained note is required. Each instrument has a definite position in its compartment before the player. The one on his extreme left and in the row closest to him is always known as No. 1, the left bell of the second row being No. 2. On the right of No. 1 come Nos. 3, 5, 7, 9 ; while on the right of No. 2 come Nos. 4, 6, 8 and "0." Thus, the nearest row consists of odd numbers and the second of even. Those in the third row, beginning at the left, are called A, B, C, D and E. These letters designate the positions on the table. They do not refer to the notes of the bells.

The Science of Bellringing. Ringers calculate by position. Pythagoras regarded music as the "Science of numbers." To-day bellringing is taught and practised by mathematical rather than aural notation. Unless the faculty of counting is cultivated the student cannot hope to excel. Before attempting to handle a number of bells, begin by practising with not more than four. Place these in their proper order. Ring all the changes on the four bells until facility in that exercise is acquired. Then add two more to the right and study the six changes. Afterwards add bells in places A and B. Finally, as progress is made, 7, 8, 9, 0 and C, D and E can be employed. It will be found that two right-hand bells frequently follow each other quickly. In that case, the first, after being struck, must be transferred quickly to the left hand. If this is otherwise occupied, both bells can be held in one hand. Instead of taking the first bell between the thumb and first finger, lift it by the second and first.

The second bell can then be taken up by the thumb and first finger. But it must be held with its handle at right angles to the first. With the flat side towards the player's body the first bell can be rung either by an upward or downward movement without the other sounding. When No. 2 should ring, a turn of the wrist will bring the flat of its handle towards the player. The clapper will then strike without a second blow being given by the first bell. Taking two bells in each hand for consecutive notes, the student should practise the scale slowly until facility in this useful method of manipulation is obtained. It is only by such means that accomplished handbell ringers can acquire mastery over fifty or more bells.

Quintet Music. For a quintet such as described, the music is written in five staves. That for the two trebles and the alto is in the treble clef, and that for the tenor and bass in the bass clef. To save space we indicate on two staves the opening bars of Costa's "March of the Israelites," marking the positions for each bell [**6**]. Notes for the first treble are indicated by the tails being turned up, while the tails are turned down for the second. These performers divide the treble work ; they do not double it. It will be observed that the C and D are sounded together in bar 7. In this case, the first treble takes the C and the second the D ; but in bell-ringing the effect is always better when sounds are arpeggioed rather than struck in chords.

To get the numbers and letters correctly, when deciphering handbell notation the student must make out a plan for himself for the arrangement of the bells in his own compartment. These, being not in the same order as the sounds are represented on a piano keyboard, may appear confusing at first. They are located rather after the method of the letters on a typewriting machine, bells most frequently wanted being placed most conveniently for the two hands. Thus, as the example given is in the key of C, both C bells are on the right of the first treble's compartment. The G, or dominant, being next frequently wanted, is placed on his extreme left. The A's, giving an interval of a third, come next to the C's, while the B's are on the right of the G. As G♯ is only needed once in the piece it is placed by itself in the third row in position A.

As the second treble divides work with the first, the bell this player will use most is the octave G above that allotted to the first treble. So this G is on the second's right. On his left is the D, and on its right the E, the F being on the left of G. In the third row, in the positions A, B and C, are the bells giving B♭, C♯, and D♯, they being only seldom needed.

Steeple Ringing. After practising the rudiments with the handbells, the student should ascend a belfry. In her ordinary position in the tower, the bell hangs downwards. When swung and struck, her hollow body emits—according to the diameter of the mouth, thickness of sound bow, height, and other proportions—several tones. These are the "Strike" note, "Hum" note, the "Nominal," a minor third and perfect fifth in the first octave, and a major third and perfect fifth in the second octave. When the bell is in tune with herself, the "Hum" tone should sound a perfect octave below the "Strike" note, which gives the pitch.

The harmonics of a bell differ from those elicited from any string or wind instrument. Each sound is regarded as a principal tone dependent on the various curves of the bell. The "Hum" note, therefore, does not follow the law of resultant tones, and the presence of the lower minor and the upper major thirds is a puzzle which, so far, has baffled the greatest acousticians. In very large bells one hears—provided she is in tune with herself—a glorious succession of octave harmonics which have a peculiar charm. It is probably owing to the presence of so many sounds that bellringers refer to "Key" rather than the note which each instrument in a peal represents.

How the Bells are Fixed. On the top of the bell, cast with her, are two rings or "cannons." Iron braces, strongly bolted, secure these cannons to the cross-beam or "stock." To this, at one end, is fitted the iron axle into what are called "gudgeons." The axle works on brass or gun-metal bearings, to prevent corrosion. On one side of the stock is fitted a broad spoke of a wheel, in diameter more than double the height of the bell, the wheel working on an axle similar to that on the opposite side.

Both axles rest on stout beams firmly bolted to the floor of the bell-tower, forming together the timber cage for the bell, shaped like three sides of an oblong. The tire of the wheel is grooved. Attached to the large spoke, the bell-rope passes through an eye in the tire. Thence, it goes along the groove, down over the wheel and through the floor over a pulley, so that it works easily, into the belfry below. The ringers thus have the floor between them and the bell. So they are neither deafened by the strongest sounds of a peal nor exposed to inclemencies of the open air. When the rope is pulled at a distance of, say, 3 ft., if the bell is that height, the result is that her mouth, instead of pointing down, is thrown skyward. The ball of the clapper, striking that portion of the lip immediately over the head of the ringer, gives the hand stroke. On the rope being released the distance of the diameter of the mouth, the flight of the clapper hits the lip in the opposite direction away from the ringer. This is the back stroke. No matter how hard the bell is pulled, she cannot make a complete revolution. The beam on which she is hung is checked by an iron stay, the flight of the clapper being restrained by a relapsing curved rod known as the "slider." A forward and backward stroke of the bell constitute a whole pull. The student should practise with the bell lashed.

Practice in the Belfry. Take a piece of fine rope and make a noose in the centre big enough to slip over the flight of the clapper; the ends must pass over the lip of a bell on either side. Protect the lash at those points with leather, to prevent cutting. Make the rope fast to the cannons at the top of the bell. When she is now pulled, there will be no tone. A bellringer, who acts as coach, should set her at back stroke. He will adjust the rope to the exact length required by the student. Below the "sallie," or plumed wrapping, a bell rope is half as long again as is likely to be needed for the shortest ringer. When at back stroke, the rope should terminate in a loop just above the student's head. If it is too high, he cannot grasp it easily. The "tuckings," in that case, must be laid down; otherwise, they are pulled up by coiling, spiral fashion, to the right point, as needed.

Having set the back stroke, the coach should place the bell at hand stroke. The student, stretching his arms to their full extent without straining, should now be able to grasp the "sallie," or tufted part. Pull the rope down carefully till the bell is brought to balance at the hand stroke. If her weight is under 10 cwt., a force of 2 lb. or 3 lb. will bring her over the balance. As soon as she is "off," put the hand not holding the end of the rope down to that end. At the back stroke let the bell carry up both hands till she is just off her balance again. Stop her there, so that she does not hit the check. Pull her "off" with the same force as at hand stroke. When the "sallie" is opposite the student's face, he must grasp it, first with one hand, and then the other. He should let the bell carry his hands up to back stroke till she is again over the balance, without allowing the "sallie" to slip through the hand. To let the rope slide is a bad habit.

Attitude. Stand upright. Do not bend the body from the hips. Unless the student stands properly, the necessary coil of rope is apt to get into his face, and perhaps round his neck. If a large bell requires strength, drop the knees slightly. The mechanism probably needs attention if she requires more than 6 lb. weight to pull her off. Keep one foot slightly in advance of the other. When a position is once taken up, adhere to it till the completion of a flourish or peal. Do not turn the whole body in looking from one rope to another. Such a habit is exhausting when a 5,000 change is rung. A turn of the eyes or head will suffice. Having mastered a lashed bell, the student may take No. 3 in rounds. He must then listen for the interval between the strokes preceding him. If No. 1 in rounds, he must allow double time after completion of the back strokes before starting off again with hand strokes.

Carillons. In contrast to the irregular effect produced by change-ringing when bells are swung, a carillon implies a greater number of bells set close together and hung dead. Enclosed in a frame, a peal, like that at Bruges or Ghent, includes 48 bells. These are struck like clocks, mechanically, by a hammer on the outside of the lip.

CIVIL ENGINEERING
39

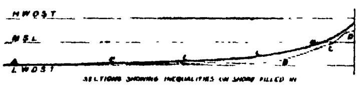
HYDRAULICS
continued from page 5497

By Professor HENRY ROBINSON

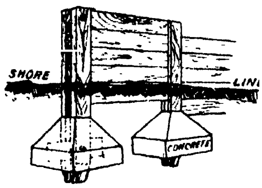
THE prevention of damage to and loss of valuable land by the constant action of the waves on the foreshores is one of national importance. At the present time there is absolutely no official and reliable record of the changes annually taking place round our coasts, and these changes are constantly affecting buildings and other works which have been carried out at a large outlay of public money. The annual loss of land in some parts of the country has been recorded, the following being a few examples which were given in a paper read before the Institution of Civil Engineers. The annual loss of land on the East Coast alone represents an area somewhat larger than the island of Heligoland.

Withernsea ..	6	yds. per ann.
Dimlington		
Easington		
Mappleton ..	2 to	
Hornsea Burton	2½ to 4½	,, ,,
Aldborough ..	2 to 2½	,, ,,

It is proposed, in this article, to consider generally the circumstances under which the loss of land occurs, and, although no rules can be laid down, to describe some of the methods employed under different circumstances for protecting foreshores from erosion.



19. CASE'S ELLIPTICAL THEORY



20. CASE GROYNE

The erosion of the coast-line is a subject which offers a wide field for investigation, which is being made by a Royal Commission. The subsidence of the land also deserves consideration.

Dr. Geikie remarks in his textbook on geology: "It is difficult to trace a downward movement of land, for the evidence of each successive sea margin is carried down and washed away or covered up. In the great majority of cases where such an advance is taking place, it is due, not to subsidence of land, but to erosion of the shores. The results of mere erosion by the sea, however, and those of actual depression of the level of the land cannot always be distinguished without some care. The encroachment of the sea upon the land may involve the disappearance of successive fields, roads, houses, and villages, and even whole parishes without any actual change of the level of the land."

Erosion is due to several causes, the chief being the scouring action of the sea on the foreshore, which is sometimes assisted by the action of rain and frost on the cliff face.

The erosion of the bed of the sea in most cases is impossible to remedy. It is due to the action of tidal and other currents and sometimes to submarine fresh-water springs.

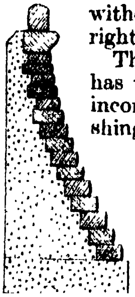
Points for Observation. The following are the most important points to be observed when considering the protection of foreshores:

1. Range of tide.
2. Direction and intensity of prevalent winds.
3. Direction and intensity of destructive winds.
4. Direction and force of 'long-shore currents, surface and bottom velocities being taken at high water, mean tide, and low water.
5. Percentage of material, per cubic foot or yard of water, carried in suspension. Samples to be taken from surface and close to the bottom.
6. Quantity of shingle or other detritus, and extent to which it is moved during different conditions of wind, waves, tide, etc.
7. Nature and depth of the marl, sandstone, or other material undergoing erosion.
8. Extent to which the sea bottom is undergoing change, especially in the matter of the formation or alteration of submerged banks causing alterations in the directions of currents.
9. Nature of material thrown on shore during on-shore gales, and the depth of water from which the material is torn.

The encroachment of the sea upon the land is a source of great anxiety to owners of sea frontages. In many cases where the land is used for agricultural purposes the pecuniary loss is insignificant as compared to the cost of protective works and the maintenance of them. This is, however, different when the land is valuable, and is required for building purposes. Then the construction of sea walls justifies the expense by affording protection to the valuable property behind them.

21. BEARD'S GROYNE

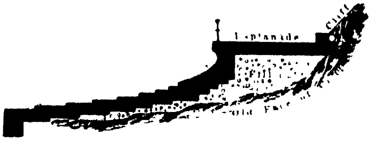
Protective Works. In many cases the expense of protective works falls on the owner of the frontage, as those owning the land immediately behind may be indifferent and prepared to wait until their turn arrives. This is obviously unsatisfactory, and as the whole question is a national one, some sort of Government aid and control is necessary. Land once lost to the sea, in many cases, cannot be reclaimed



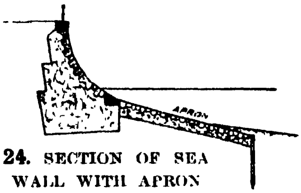
without involving questions of foreshore rights.

The action of a wave on a foreshore has two distinct results, that of the incoming water driving the sand and shingle up the beach, and, as the water retires, drawing the sand and shingle back into deep water. This material (or travelling beach) is deflected seawards, and is carried elsewhere, forming sandbanks and shoals. The place of deposition of the eroded matter is difficult to locate, as it is sometimes carried in suspension great distances. The arresting and depositing of this travelling beach is attained by groynes, properly arranged and constructed, whereby the beach level is raised.

22. SECTION OF SEA WALL

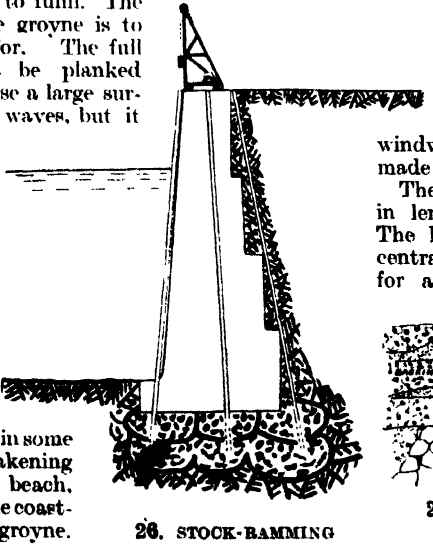


23. SECTION OF SEA WALL WITH APRON



24. SECTION OF SEA WALL WITH APRON

Groynes should be constructed in such a manner as to direct the power of the sea in depositing the drifting sand or shingle where it is needed, and to retain it in position. In this manner the beach level and foreshore are gradually raised. To assure this result a thorough knowledge of the tides, etc., on the coast under consideration must be obtained in order to settle the position, number, and distance apart of the groynes, which should be carried down to low-water mark if practicable. The construction and strength of the groynes must depend on the locality, and on the conditions which they will be required to fulfil. The ultimate height to which the groyne is to be carried must be provided for. The full height, however, should not be planked immediately, as it would expose a large surface to the full force of the waves, but it should be raised as the sand or shingle accumulates at the groyne. It is a matter of opinion as to the angle at which the groynes should be placed, but the writer does not agree with the assumption of many that all groynes should be placed at right angles to the shore. Unless the groyne is placed at the correct angle the shingle will be found to collect on the windward side and not on the leeward, causing a drop, in some cases of many feet, thus weakening the groyne and disfiguring the beach, while no protection is given to the coastline on the leeward side of the groyne.



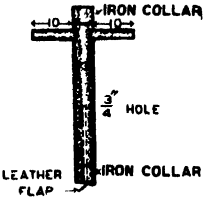
26. STOCK-RAMMING

Different Types of Groynes. The late Mr. Edward Case considered that the correct form of any shore composed of beach, sand, or any other shiftable material was a gradually sloping surface, the section of such shore between high and low water marks being an ellipse, the construction of which depended upon the range of tide and the horizontal distance between high and low water marks.

According to this elliptic theory, the shore should follow the curve *e e e e* from the point A upwards [**19**] and, if suitable material can be introduced, and this curve be arrived at, the sea should do no further damage, but should roll harmlessly in and out.

To obtain this result Mr. Case placed groynes constructed of light timber [**20**] between low-water mark and mean sea-level, and normal to the curve of low-water line, in order to trap the travelling beach. This system of groyning has been successfully employed at various places.

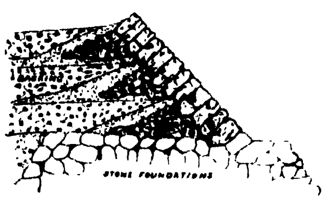
Another system of groynes is that invented by Mr. E. T. Beard, and is known as *Beard's Contour System* of groynes. This system has been employed at several places with success, notably at Cooding, Bexhill, in Sussex, where Mr. Beard informed the writer, in January, 1906, that the high-water mark has been driven 120 ft. seawards, and the beach level had been raised 19 ft. The special feature of this system is the *ramp* which divides the groyne into two portions as shown by **21**, the upper one to retain the permanent beach and the lower one to permit the drift to pass freely over the groyne.



25. STOCK-RAMMER

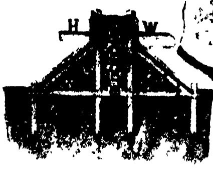
At Cooding the groynes were required to protect land lying behind a narrow shingle bank in which breaches had been made by the sea, the level of the land being below high-water mark. The length of these groynes was 328 ft. spaced at the rate of eight to the mile. The angle that the windward side of the groynes made with the shore was obtuse.

The piles, or uprights, varied in length from 10 ft. to 25 ft. The longest is placed at the central portion of the groyne for a length of 60 ft., where

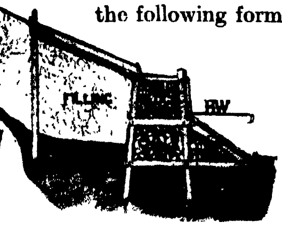


27. RUBBLE WALL FOR PROTECTING BANKS

the greatest force of the sea was expected. These long piles were also bedded in concrete, and were provided with land ties placed in two tiers one above the other and bolted to a main pile and between a pair of walings, 6 in. by 9 in. These ties were all placed on the windward side of the groyne. Wrought-iron tie rods were fixed at intervals to the upper portion of the long piles to give additional strength to the groyne. The planking was 2½ in. thick, spiked to the windward side. The upper portion of the groyne was constructed level, and then fell 3 ft. in 120 ft. to the *ramp*, or quick fall of 6 ft. in 20 ft., followed by a fall of 16 ft. in 148 ft., making the total length of the groyne 328 ft.

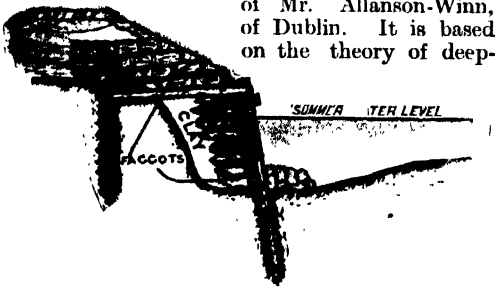


28. TIMBER AND RUBBLE GROYNE

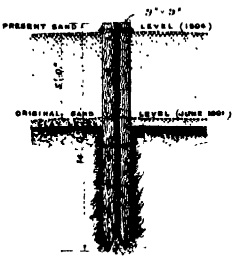


29. PROTECTIVE WORKS FOR FORESHORE

The Cable Groyne. A new method of protecting foreshores from the sea has recently been employed at Bray. This system is known as "cable groyning," and is the invention of Mr. Allanson-Winn, of Dublin. It is based on the theory of deep-sea erosion—that is, of erosion of the ocean bed below low-water mark and the consequent driving forward of the low-water line. In order to prevent this erosion, and to encourage the deposit and retention of the material, Mr. Winn employed chains (the weight of which must vary according to the locality). To each of the chains were attached trees, crates, faggots, etc., one end being fixed to a pile placed near low-water mark, the other being anchored out at sea at any distance or depth of water, thus forming a flexible hedge-like groyne below low-water mark. After a few weeks observation, Mr. Winn found that some few feet of sand and shingle had been collected by the groynes, which were soon entirely buried.



30. TIMBER PROTECTION FOR BANKS



32. WOODEN GROYNE

Waves. The height of waves is an important factor in dealing with sea walls, groynes, etc. The height likely to be attained at any locality by waves may be calculated, as they are found to be nearly "the ratio of the square root of their distances from the windward shore," or when h = height of wave, d = distance, and a = coefficient varying with the strength of the wind, then $h = a\sqrt{d}$. This formula (Stevenson's) may be taken to be $h = 1{\cdot}5\sqrt{d}$ in heavy gales, and in seas which do not differ greatly in depth.

In short reaches and in violent squalls, the following formula should be used:

$$H = 1{\cdot}5\sqrt{D} + (2{\cdot}5 - \sqrt[4]{D}).$$

The force of waves may be calculated from the following formula: Let

x = the greatest force that can assail a pier, etc.,

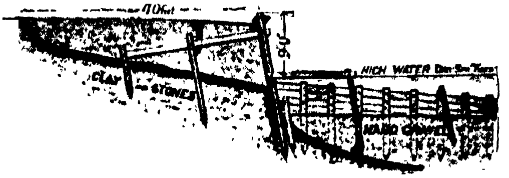
h = height of waves due to the maximum effective exposure,

a = azimuthal angle between directions of pier and maximum exposure,

then, when the force is resolved normal to the line of the pier, x varies as $h \sin^2 a$, but if the force be again resolved in the direction of the waves themselves, x varies as $h \sin^3 a$.

The direction of waves is often altered when approaching the shore, this being due to the change of depth of water.

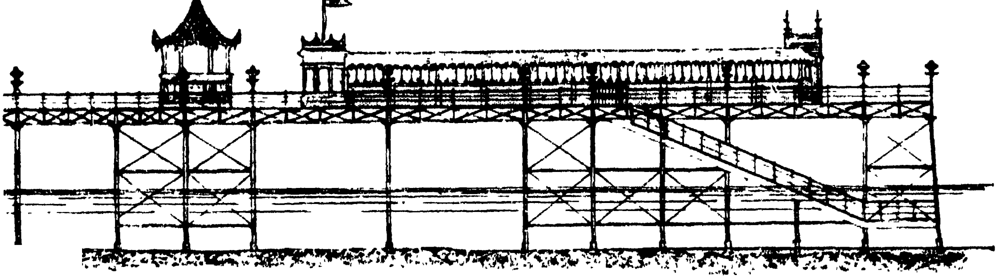
Sea walls are constructed in places where valuable property is to be protected, and, as before stated, their cost is justified. It is often found necessary to construct groynes to protect sea walls. The scouring action of the waves removes the beach, exposing the foundations, which are eventually undermined, and would, unless protected, result in the wall collapsing. The resistance of the wall to the waves causes the water to be thrown high up into the air, and in falling it scoops out and undermines the foundation. There are several methods of guarding against this. The face of the wall may be stepped, as in **22**, or an apron of stones may be formed [**23** and **24**] to protect the toe of the wall. Where the wall has been constructed on hard rock, no such precautions may be necessary, as shown in **22**.



31. TIMBER GROYNE

Great care must be taken in constructing masonry or concrete sea walls or piers, on account of the action of the waves on cavities in the work. The air contained in a cavity is compressed by the impact of the waves, and in time disintegrates the work.

Stock-ramming. A method (first employed by the late Mr. Kinipple) for filling cavities and solidifying foundations is known as *stock-ramming*. It has been employed extensively and is worthy of description. The simplest and cheapest form of solidifying foundations, stopping leaks, or filling cavities, is by stock-ramming. By this method liquid Portland cement grout is forced by a stock-rammer [25] through a tube or pipe into the crevices of the foundation; it solidifies, and forms a sound base. Should the foundation of the wall be sand or gravel, and it is desired to solidify the stratum to prevent settlement, series of boreholes of from 2 in. to 6 in. in diameter are sunk at intervals along the line of wall. Pipes are inserted and grout is forced into the stratum on which the wall is constructed. Another method, where the stratum is soft, is to force into it balls composed of hydraulic lime mixed with clay, sand, and iron filings mixed with sal-ammoniac, Medina cement, or half-set Portland cement. These balls are driven down the tubes into the soft substratum by rams. On setting they form a hard foundation for the wall. Figure 26 shows this method in operation.



33. PIER HEAD

Protective Works. The following are brief descriptions of types of protective works: Figure 27 shows a form of rubble wall for protecting a bank which is not exposed to heavy wave action. Figure 30 is a method known as *facining*, for protecting a bank under similar conditions as 27, being commonly used for rivers.

34. DESIGN FOR PIER HEAD

Piles constructed from tree trunks are driven firmly into the ground, as shown by the illustration [30], and are braced together, the face of the bank being protected by close rough planking with a backing of faggots and clay. The foot of the bank is protected by heavy stones. This form is unsuitable if exposed to wave action.

Figure 31 shows a method of protecting foreshores where they are exposed to considerable wave action. This groyne, if properly placed, collects the drift, thus raising the level of the beach.

Figure 29 is an illustration of a protective work for a foreshore where there is heaving wave action. The timber framing is filled with block chalk, being enclosed by a facing of open planking. The toe is extended, as depicted by the illustration, to afford protection against undermining. Figure 28 shows another form of groyne. The block chalk or rubble is, in this case, enclosed by open planking. Figure 32 is a section of a wooden groyne commonly used for foreshores.

Piers. Piers may be classed under various heads. Some serve the purpose of discharging goods and passengers at seaports, or on rivers, like those at Dover, Folkestone, Liverpool, etc. Others serve the double purpose of training the course of a river, as on the Tyne, where two solid concrete piers are carried out to sea on the north and south sides of the mouth of the river. The object in this case was to confine the water in a defined channel at ebb tide, and so to remove the bar, which previously had to be constantly removed, or lowered, by dredging. The object has been accomplished, and a greatly improved navigable channel has resulted. The construction of piers in connection with harbours is dealt with in another section. We shall confine ourselves to brief reference to promenade piers which are a feature at many seaside resorts.

Figure 33 is an illustration of a promenade pier which the writer designed for a watering-place where it was desired to combine a means of landing passengers from pleasure boats, steamers, etc., with arrangements for bathing, together with the usual bandstand, refreshment rooms, etc. In this case the planks of the deck rested on girders supported on cast-iron piles.

The next illustration [34] shows in plan another pier that the writer designed for a simliar purpose. The planking of the deck is bolted to longitudinal iron girders resting on the iron cross girders placed on the top of the iron columns sunk into the foreshore and forming either a group of piles or merely two, if the width of the deck is small. The method of constructing the pier in all the details will be dealt with in another section, which treats of the design of piers.

THE SUCCESSFUL CATERER

The Principles Underlying Efficient Catering. Rules for the Good Housewife. Country Tea Cottages. Confectioners. Management of Restaurants

By A. B. BARNARD

WHETHER catering is to be done for a small household of four or five, or for a big institution such as an hotel, certain principles underlie its efficient performance. We will state them summarily in the following paragraphs.

No thrifty housewife buys anywhere haphazard, nor does she, in a conservative spirit, continue to deal year in year out at the same shops. From time to time she compares the advertised prices of various firms with those she happens to be paying. The quality of the goods supplied must also be considered. For instance, it is false economy to buy inferior butter because it happens to be 2d. or 3d. per lb. lower in price than elsewhere, or dusty, stalky tea at 6d. per lb. less than that of a good blend. Such test purchases are possible in all large distributing centres, but outside these the caterer is more or less dependent on the local dealer, failing whom, it is best to order groceries direct from London stores or those of some large provincial centre. The street vendor of vegetables and fruit is not to be despised, for his price is usually less, and the articles often fresher, than those at shops. After a few experiments reliable dealers may usually be found, who are well pleased to get good, paying customers on whose orders they may depend. In the case of greengrocers and fishmongers, freshness and good quality of the provisions, and punctuality in their delivery are two most important points of recommendation. It is annoying to have a dinner spoilt by the non-arrival of a joint or poultry, or to receive it in an uneatable condition.

Knowledge of the chemistry of foods is of great value, since on it depends the making of dietaries and the planning of good menus—good in the sense that the dishes supply the right amount of flesh and fat-producing foods required to keep the body in a healthy and well-nourished condition. [See PHYSIOLOGY and HEALTH.]

Knowledge of How and When to Buy. Conservatism in diet is the great stumbling-block of English housekeepers, who fail to realise the great importance of ringing the changes on available food supplies. Our versatile neighbours across the Channel lift their hands in dismay at the automatically recurring porridge, bacon, bread and butter, eggs, and again porridge, bacon, bread and butter, eggs, year in, year out. Heat-producing porridge and fried bacon on a hot summer morning! Good digestion waits on appetite, yet how unappetising are many of our meals. In hot summer weather why not try one of the following by way of a change: cod-fish balls, soft roe (bloater's) on toast, steamed apples and oatmeal, tomatoes and eggs, tomatoes and macaroni, dates and whipped cream, sliced bananas and cream, or figs and hominy?

Some provisions are economical purchased in large quantities, providing, of course, that there is room in which to store them. Certainly those who manage hotels, boarding-houses, and institutions of various kinds should lay in stocks of potatoes, apples, onions, sugar, tea, bacon, flour, rice, tapioca, pickles, dried herbs, and condiments; these, together with jams, preserved fruits, and biscuits in tins, keep well in a dry and airy store-room or cupboard, and are less expensive purchased in bulk.

Economical buying does not necessarily mean purchasing at a low price, since a cheap article is often the dearest in the end, but getting the best return for expenditure. The ability so to do is perfected by experience, but rests mainly on knowledge, commonsense, and forethought.

The times when certain foods are in season need to be known and tabulated for reference, for in this way the thrifty caterer keeps in touch with times and seasons, and runs no risk of paying fancy prices for articles nearly or quite out of date. Oysters will not be ordered in July, cauliflowers in December, pork in August, nor rabbits in May. [See Table of Provisions, page 1531.]

Economy and Cleanliness. A thousand and one economies are practised by good providers, who bear in mind the maxim, "Waste not, want not." There are various ways of using up odds and ends, especially in the case of cold meat. For these the reader is referred to Cookery.

Our French neighbours show their greater economy in cooking in a variety of ways. They utilise the head and feet of a fowl, the eyes of a fish, the brains of a horse; the last, in fact, appears in the dietary of an invalid. Thus, parts of an animal which we despise and throw away aid in the production of tasty dishes. Then again, to what an extent are plants, some of them regarded as weeds by us, used across the water. An excellent salad is there made from dandelions, and wood sorrel can be employed in the same way. Nasturtium leaves may be utilised for sandwiches, mountain-ash berries and hips for jam, young nettle leaves as a substitute for spinach, and maize for porridge.

In planning menus, not only is a knowledge of the constituents of foods desirable, but also foresight in the ordering of provisions. To ensure this, daily visits of inspection should be paid to the store-room, so that any article running short may be renewed in time, and the cook will not suddenly discover that she wants potatoes, baking-powder, or pickles.

There is no more certain road to failure for the restaurant or tea-shop than want of cleanliness in either the preparation or serving of food. Customers will pass the door of a place which recalls unpleasant memories of smudgy plates and glasses, stray substances where they ought not to be, and tablecloths suggestive of microbes.

Detection of Adulterated Food. A caterer should always be on the look-out for adulteration in articles of food. Tea is much adulterated by intermixture with elm, beech, elder, oak, willow, and hawthorn leaves, unscrupulous dealers not hesitating to mix dried or exhausted leaves with good ones; coffee is adulterated with mahogany sawdust or coloured beans, cocoa with starch, bread with potatoes and alum, and butter with mutton fat. Chicory may be detected by scattering a sample on cold water—the coffee, which contains oil, floats; the chicory sinks, leaving a coloured streak. Mustard is adulterated with wheat or rice flour: to detect this the alleged mustard should be boiled and a few drops of tincture of iodine added. This will colour the flour blue. A short time ago a girl who was admitted to a London hospital was found to earn a living by making wooden seeds for raspberry jam.

Good Accountancy. Daily provision for the needs of the family presents to the majority of people the most familiar aspect of catering. Partly in imitation of Continental ways, and partly to evade the domestic servant trouble, there is a growing tendency in cities to take all meals, except breakfast, at hotels and restaurants. In up-to-date West End flats a restaurant will be found on one of the floors, to which a lift conveys the residents with less exertion than is required to reach the dining-room of a country mansion. Such conditions are at present exceptional, however, and most housekeepers cater for their own families. Naturally, the cost per head per week depends on the style of living. For a family of over four people 15s. is a very usual allowance, and permits of good living; 10s. would be enough for a nice table; 8s. 6d. provides a sufficiency, and, with careful management, 6s. will obtain enough plain nourishing food; 17s. 6d. to £1 should provide very good living. We are, of course, supposing normal conditions—efficient and economical management, average appetites, and markets which are easily accessible.

The locality of the house considerably affects the weekly expenditure for food, a shop in a district catering only for wealthy customers charging proportionately high while another in a less fashionable neighbourhood has a lower scale of charges for similar goods.

Rules for the Household Caterer. The household caterer should bear in mind the following rules:

1. Do your own marketing, and see a thing before you buy it. Butchers have a little weakness for sending a larger joint than the one ordered.

2. Pay cash, run no bills, and so get the best quality at the lowest price in addition to independence of custom.

3. Study price-lists, and avoid cheapened foods.

4. Buy foods in season.

4. If possible, carry home your purchases, as Continental housewives do. They are seen early abroad carrying provision baskets, or followed by a maid doing so.

5. Give plain, straightforward orders if you wish for good service.

It is false economy to stint the members of the household of good, nourishing food, for the shillings so saved are apt to find their way into a doctor's pocket. The problem is to know what foods and what quantities are necessary to produce the maximum efficiency of all the vital functions. Then, too, one man's food is another man's poison. Eggs are positively injurious to some people; sugar is necessary to children, and fat to thin persons. The diet of children should alter with their growth. Some persons with quick digestions need a light meal every three hours, and may even require a relay of refreshments by the bedside. Hence there can be no hard-and-fast rules for dietaries, and home catering affords scope for intelligent study, observation, and experiment.

We now proceed to discuss catering for the public in various ways, beginning with the humble sphere of the street vendor.

Street Hawkers. A familiar feature of suburban life is the barrow on which fish, vegetables, fruit, ice-cream, mineral waters, potatoes, or chestnuts are hawked about. In the unfashionable districts of a city the street seller can, for a few shillings, lay in a stock of his wares, and if he be a capable buyer and secure a good pitch, may in his limited line prove a formidable rival to a neighbouring fruiterer, who has rent to pay, while the costermonger either owns his barrow or hires it for a small consideration. The man is usually aided by his wife or daughter, and gets regular customers on his rounds. He must be early at the market—Covent Garden or Billingsgate, and, as he is out in all weathers, has a rougher life than his brother in the sunny climes of the South, where street sellers are ubiquitous.

Villages have usually some kind of ginger-beer shop—where ginger-beer or lemonade is bought at 9d. a dozen and sold at 1s. 6d.—or a small inn as the only place offering refreshment to the wayfarer; and usually the food, surroundings, and charges are anything but satisfactory. Owing to the increase of cyclists and motorists, there is a good opportunity for women to start tea-rooms catering for such customers, preferably near villages or small towns.

Country Tea Cottages. An attractive cottage on a high-road, say, along the Thames Valley, would answer the purpose, provided it had a garden with flowers and a few shady trees in front, under which afternoon tea could be attractively set on small tables. A legible and artistically-painted sign board, indicating that refreshments or teas are there provided, should be placed in a prominent position. To make such a venture, a capital of a few pounds is wanted to buy tables, chairs, table-linen, crockery, and cutlery; but in order to insure success and pocket £30 to £50 profits, spotless napery, dainty tables, prompt service, good bread (preferably home-made), butter, cakes, jam, cream, and tea or coffee are required. Home-made lemonade is always appreciated. Mustard and cress and salad from the garden, eggs from a poultry run at the back, watercress from a neighbouring stream, and home-made preserves might go to increase the profits as extras. Necessarily, a room or shed should be available in bad weather. Cyclists and motorists prefer a dainty tea costing about 1s., nicely served in pleasant surroundings, to that obtainable in a stuffy inn, and would probably recommend it to friends. Undoubtedly a demand for such refreshment places exists, and to two or three practical girls desirous of adding to a limited income such a scheme presents possibilities.

Confectioners and Bakers. Apart from the regular business of the baker and confectioner, refreshments are provided in their shops. Teas for 6d. or 8d. (including tea, two slices of bread-and-butter, one cake or pastry) would cost about 3d., yielding half profits. Tea, bread-and-butter, cake, jam, with lettuce or watercress supplied ad libitum, for 1s. would prove very profitable. Ice-creams give a full half profit or more, such as sell at 6d. costing a little over 2d. Milk-and-soda, home-made lemonade and sweets are specialities which can be made to pay well. Some women who have had a small confectioner's business and have made a modest beginning by "obliging with a cup of tea," do quite a large business in lunches, teas, and breakfasts. Outside catering for supper parties, afternoon weddings, At-homes, musical parties, Cinderella dances, conversaziones, and children's parties, is a natural offshoot, and usually yields somewhat less than half profits.

Charges for Parties and Dances. We here give arrangements, menu, and charges for such entertainments, as furnished by a suburban confectioner:

Charges: 50 guests, 3s. 6d. per head; all over 50, each person, 3s. 3d. 100 guests, 3s. per head; all over 100, each person, 2s. 6d. 150 guests, 2s. 9d. per head; all over 150, each person, 2s. 3d.

Menu: Tea, coffee, white bread-and-butter.

Ices: Strawberry cream, vanilla cream, lemon, water (others if required).

Iced drinks: Lemonade, claret cup, mineral waters.

Cakes: Madeira, pound, cherry, etc.

Biscuits of various kinds, macaroons.

Fancy pastry of various kinds.

Assiettes of sandwiches: Ham, tongue, eggs, and cress, etc.

Lobster and oyster patties, etc.

Lemon jellies, strawberry cream, meringues, tipsy cake.

Dessert (in season).

For suppers: Consommé soup (on departure).

This includes use of all plate, glass, china, buffet tabling, silver urns and candelabra, and plants in silver pots. The services of waiters and waitresses are also included. Dishes left over are returned.

Ball suppers can be provided in an hotel at 5s. per head per 100 guests.

For a £1 menu would be provided sandwiches, boned turkey or bird, mince-pies, sweets (jellies, blancmange, creams), fruit, lemonade. Waitresses in this case are charged for at 10s. or more, according to contract.

In the case of wedding breakfasts, the bride's cake is, of course, not included. At a good hotel a wedding breakfast can be provided at 15s., 17s. 6d., £1 1s., or £1 5s., according to the menu. Such entertainments are, however, since the extension of the hour of the marriage service from 12 to 3 o'clock being superseded by the more desirable wedding tea, which not only permits a larger number of guests, but may be served in the garden.

The charge per head for school treats ranges from 4d. to 9d., the latter sum providing tea, bread-and-butter, cake, and jam. Lunch for teachers and visitors at school treats is supplied at 1s. 9d. to 2s. a head.

Occasionally a confectioner's shop is situated near some public ground or park, where cricket and football matches, flower shows, and fêtes are held. This is an opportunity for the confectioner to supply tea, bread-and-butter, cake, jam, with lettuce or watercress ad libitum for 1s. Large cricket and tennis clubs run their own refreshment-rooms in the club buildings, and make considerable profit thereby in the season.

Large hotels have ample accommodation for dinners, wedding receptions, and ball suppers. When rooms are not specially built for the last purpose, the coffee and billiard-rooms may be utilised, the coffee-room for dancing, and the billiard-room as a buffet.

London Tea-shops. To give an adequate account of London tea-rooms and restaurants is a gigantic task. The "London Directory" gives a list of 414 refreshment-rooms, 762 dining-rooms, and 1,712 coffee-rooms, making a total of 2,888 eating-houses. Allowing each 200 customers a day gives a total of 600,000 meals, probably only a small portion of those actually supplied. Time was when the City man regularly took up to town a tin of sandwiches for his lunch; now establishments of the Aerated Bread Co., Ltd., J. Lyons & Co., Ltd., Slaters, Ltd., the Cabins, Ltd., the British Restaurant, Ltd., and others are found east and west, north and south. At such places a cup of tea or coffee costs 2d. or 3d.; roll and butter or cut bread-and-butter, 2d; cake or pastries, 1d. or 2d. According to the "Stock Exchange Year Book" for 1906, the following dividends were issued in 1904-5: J. Lyons & Co., Ltd., 30 per cent.; Aerated Bread Co., Ltd., 6s. 6d.; Slaters, Ltd., 16 per cent.; Express Dairy Co., Ltd., 2½ per cent. for the half-year ending in August, 1905.

Artistically decorated tea-rooms of a higher grade are increasing in the West End, and are used as lounges. The large stores and drapery establishments have found it necessary to attach tea-rooms for their exhausted customers.

Restaurants. The successful restaurant of the present day must not only provide a lunch or dinner daintily served and well cooked, but it must be eaten in an artistically decorated room, with smoking, card, and chess-rooms attached. The restaurant of the future promises to be very luxurious, containing bath-room, reading-room, and hairdresser's—a place, in fact, where the whole day may be spent.

The custom of giving dinners and supper parties at restaurants and hotels instead of at home is on the increase, partly due to the saving of trouble and also to lack of space in flats and difficulty of getting reliable domestic help.

For the benefit of those who dine à la carte, it is usual for a restaurant to display at the entrance the menu for the day, with the price of each dish; thus the City youth can estimate to a penny the cost of his meal—say, 6d. for meat or fish, 2d. for vegetables, 3d. for pudding, and 1d. the waitress. The last item runs to 1d. in the shilling, or 2d. in the shilling in high-class places. In the same restaurant luncheon à table d'hôte at a charge of 1s. 6d. (four courses) is common, ranging elsewhere up to 3s. or 3s. 6d. There is good scope for a shilling table d'hôte lunch, and it has recently been started as an experiment by the Aerated Bread Company, a typical menu including green-pea soup or fried turbot; roast beef, stewed rabbit or cold meats; potatoes, sprouts: rice pudding and prunes, or cheese and celery. With such a liberal menu, the portions cannot, of course, be very ample.

Let us examine (1) a City restaurant, established nearly thirty years, and (2) one of the modern type.

The Old-established City Restaurant. The restaurant we have in mind lunches, on the average, 400 people daily. The rental, rates and taxes amount from £600 to £700 per annum. The staff totals 30 persons—18 in the kitchen, six waitresses, and six at the counter and cashier's desk. The wages in the kitchen are from 12s. to 20s. per week, with board and lodging if required. Waitresses get 5s. per week, with board and lodging, their total earnings, including tips, amounting to some 30s. a week. Their average hours are eleven a day. Once a week they get off at four, and once a month have Saturday free. There is an annual holiday of nine days in summer, four days at Easter, Christmas and Boxing Days, and all Bank holidays; no Sunday work. The waitresses are trained from the time they leave school, and remain for years, leaving usually to marry. The wife of the proprietor personally supervises the kitchens. The same tradesmen have been employed for some 27 years. Orders are sent them each night for the next day, and they quite understan [illegible] inferior provisions would be returned; hence the food is of excellent quality. Arrangements are also made with market salesmen. The kitchens are underground, but the difficulty of ventilation has been removed by the use of Blackman ventilating fans. By means of two Ewart geysers, boiling water is obtained a minute after the gas is turned on. The kitchens are whitewashed three times a year, and the whole place is scrubbed down daily. One lift conveys the plate ordered, bearing a slip of paper initialled by the waitress through whom it was ordered, the other carrying down the empty plate. Broken food is given away.

It will be evident that such a restaurant, conducted in a homely fashion, has its own clientèle, which needs careful working up. Let us now consider one managed on different lines.

The Modern Restaurant. This restaurant belongs to a limited company, is conducted by a lady manager, is open from 9.0 to 7.0, provides some 300 lunches, and serves some 400 customers daily. Provisions are weighed and measured as they come in, and include 100 lb. of meat (Scotch beef, New Zealand mutton, and English meat), 18 lb. of fish, 3 cwt. of potatoes, and other vegetables by the sack or dozen. There is no place for cold storage, but supplies are obtained through provision merchants and contractors. The chef is English, foreign chefs having usually proved uncertain in temper, violent in language, and wasteful. The kitchen staff also includes two boys, who clean knives, perform pages' duties, clean brasses, and do most of the outside work, a general help, one girl for plates, and another for light washing up; also vegetable and pastry-cooks. The floors are scrubbed before 10.30, the whole premises and staff being ready for business by 11.30.

The charges for table d'hôte lunch are 1s. 6d.; à la carte—meat 6d. or 8d., vegetables 2d., sweets 3d., bread 1d., coffee 2d. Sixpenny teas provide one pot of tea, three slices of bread-and-butter, jam, marmalade, or watercress, and pastry or a piece of cake; but they have not "caught on," the same articles ordered separately, and costing 7d. in all, being preferred, so imperative is Dame Fashion. Exclusive of rent, gas, rates and taxes, the business returns half profits. It has been found by experience that a woman makes the most trustworthy and efficient manager—that is, of course, provided that she has special qualifications for the work, and does not follow the bad example of the male manager in leaving his post at will and failing to check weights and quantities.

Work and Earnings of Waitresses. The waitresses include eight in the two main rooms, six in the dining-room, and two in the smoking-room, besides a cashier. A dressing-room is reserved for their use; their hours are 9.0 to 7.0 daily, and 9.0 to 3.0 on Saturdays, with one week's holiday in summer. On arrival in the morning, they dust, spread fresh cloths, clean silver and cruets, and arrange the tables by 11.0. The charge of three tables with six customers at each is the portion of each girl. She takes her meals on the premises as opportunity offers. The wages are 6s. a week, and as 5s. a day represents the best harvest of tips, she depends mainly on these. Earnings of £1 to £1 10s. a week are exceptional. By the way, the announcement "No gratuities" is misleading and unfair to the girls. A system which provides an insufficient living wage, and leaves it to the waitress to get what she can out of a customer, is a degrading and demoralising one. Waitresses are even known amongst one another as "penny girls" and "twopenny girls." The non-tippers are called "slopers." Threepenny tips are things to be remembered, and experienced hands regard 2s. 6d. to 3s. 6d. in tips an average for a hard day's work. It may be remarked here that some firms deduct from wages so much for breakages, whether done or not, make the waitresses provide their own uniform and pay for the washing of collars and cuffs.

In our up-to-date restaurant the chef starts with a salary of 32s. a week, rising to 60s. a week, with a bonus of two guineas when the profits exceed a certain percentage.

Methods of Ordering Provisions. One restaurant company runs its own shops—butcher's, dairy, etc.; others send an agent to market. One has a distributing centre, where a staff of 2,000 is engaged in cooking and preparing provisions to be distributed at the various depôts, and where cakes, etc., are made during the night. It has its own buyers. Dairy produce is bought in the open market, and teas are obtained direct from India and China, and blended. Here the waitresses are paid 10s. a week and commission, and the annual holiday lasts from one to three weeks, according to the length of service.

The various coffee-houses and vegetarian restaurants claim a few words, since they are run on peculiar lines. The former are often dead failures, because they lack cleanliness and brightness, and thus instead of encouraging temperance drive would-be customers away. The latter are winning favour and increasing in number, for a well-managed and attractive place has a good prospect of success; one, with Oriental decorative work, which makes a feature of Indian, American, and Italian dishes, and provides a table d'hôte or à la carte lunch for 1s. 6d., and dinner for 2s. 6d., is very popular.

Coffee-stalls outside railway termini are open early in the morning for the late wayfarer or early worker. They supply a slice of bread-and-butter for ½d. and a cup of coffee for the same sum, and are largely patronised by workmen who come up to the City in the early trains.

Waiters and their Tips. The method of payment of waiters varies even more than that of waitresses. They may be paid a fixed wage and commission, a commission only, or may even pay for the privilege for working, recouping themselves entirely by tips. Such a livelihood is, of course, precarious, yet many find it profitable. In high-class establishments in London they may earn from £150 to £200 a year. At a well-known West End restaurant, where thirty waiters are employed, they are at work early in the morning preparing the hors-d'œuvre, go off duty till 5.30, return and work till 12.30. They are foreigners, who usually have the advantage over English waiters in being well trained and knowing several languages. At this same restaurant an excellent dinner of eight courses is provided for 2s. As the proprietor remarked, success depends entirely upon one's skill and knowledge of the business. One man, a few doors off, could not provide a similar dinner at 3s. 6d. In forty years he himself has reaped a fortune. As another instance of fortunes made in restaurants, one might quote the founder of "à la mode Beef Dining-rooms," established in Gracechurch Street in 1837; he left a fortune of £40,000.

As vegetarianism appears to be winning converts, we shall probably before long be well supplied with restaurants of this type.

ARTIFICIAL MANURES

Potash, Phosphates and Nitrates. Agricultural Consumption in United Kingdom. Sources, Manufacture and Analysis

Continued from page 5471

By CLAYTON BEADLE and HENRY P. STEVENS

Owing to the removal of certain constituents of the soil by growing plants, the land will soon cease to yield full crops unless artificial means are adopted to make good this loss. There are a large number of elements which are essential constituents of plant food, and Nature yields an abundant supply of most of these in the soil, air and rain. On the other hand, the elements potassium, phosphorus and nitrogen are present either in insufficient quantity or in a form not readily available to the plant if large yields are required. Different plants require the addition of different constituents, and for all information dealing with the practical application of manures we must refer the student to the course on Agriculture. We are concerned here only with the fact that compounds of potassium, phosphorus and nitrogen are required which must be available to the plant, and we shall show whence they may be derived and what manufacturing processes they undergo to prepare them in a suitable state for application as manure.

Potassium Salts. We have in our own country an ample supply of sodium compounds in the form of salt deposits, such as those in Cheshire and elsewhere, but we have no corresponding potassium salts close to hand, and we are, like most other countries, largely dependent on supplies from Germany, and apparently we shall always be so.

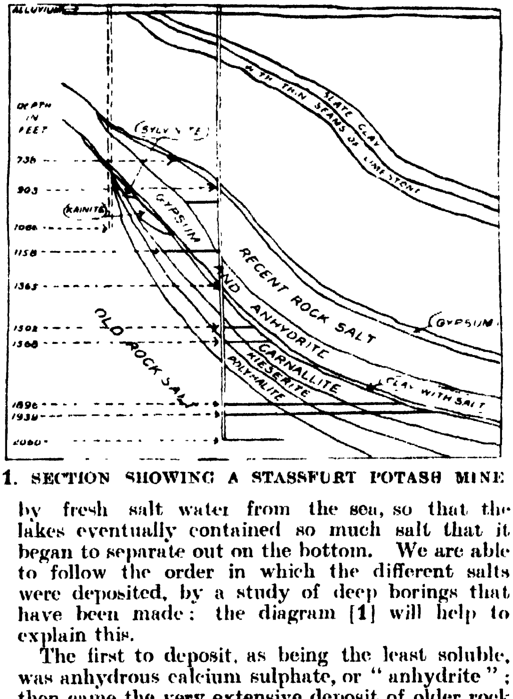
The rock salt deposits have been worked for very many years at Stassfurt, in Saxony, and about 40 years ago deep borings were made to see if a better supply could be discovered, with the result that enormous quantities were found a thousand feet or more below the surface. Above the deposit termed the "older rock salt," were large quantities of saline substances which were originally thrown aside as useless and termed "abraum salt," as they had to be cleared away to get at the rock salt (German, abräumen). It was not until some years later that people began to realise that these salts, containing large quantities of potassium, were of far greater value than the rock salt itself, and that they would eventually constitute the greater part of the world's supply of potassium compounds. Previous to this we were dependent for our supplies of potash on other sources, which did not, however, yield a fraction of what is now produced at Stassfurt.

The word *potash* is derived from "pot ashes"—that is to say, the ashes left in pots after the burning of wood. Wood, like all vegetable matter, contains certain potassium salts which are left as potassium carbonate in the ash.

Similarly, potassium salts are obtained from the residues of the beet sugar industry and kelp, certain varieties of sea-weed formerly much used in the manufacture of iodine. India also produces a certain quantity in the form of potassium nitrate: but all these sources together do not amount to more than 20,000 to 30,000 tons per annum, while the output of the Stassfurt beds amounts to 3,000,000 to 4,000,000 tons.

The Potash at Stassfurt. It must not be supposed that chemically pure potash is found in the earth and simply has to be dug out in this condition. Not only do various salts of potash occur, such as the chloride, sulphate, etc., but they are found in combination or admixture with sodium and calcium salts.

These *salt beds*, as they are called, were probably formed by the evaporation of the water of inland salt lakes, connected with the ocean by narrow channels. As the water evaporated, it was replaced by fresh salt water from the sea, so that the lakes eventually contained so much salt that it began to separate out on the bottom. We are able to follow the order in which the different salts were deposited, by a study of deep borings that have been made: the diagram [1] will help to explain this.

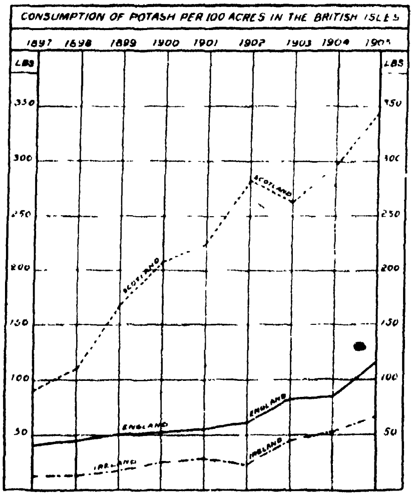


1. SECTION SHOWING A STASSFURT POTASH MINE

The first to deposit, as being the least soluble, was anhydrous calcium sulphate, or "anhydrite"; then came the very extensive deposit of older rock salt. This bed is 3,000 ft. thick, and is supposed to have taken 13,000 years to form. Above the rock salt came in order a number of combinations, or, rather, mixtures of different salts in definite proportions: polyhalite, kieserite, carnallite, kainite and sylvinite. Of these, carnallite, a double chloride of potassium and magnesium, $KClMgCl_2 6H_2O$, is the most important. Above this is a narrow layer of salt clay. Now, clay is impervious to water, and the narrow layer formed a watertight roof to the potassium salts underneath. Had not clay been deposited, potassium salts would never have been found there, but would have been washed away long before by underground waters. On the top of the salt clay is a deposit of anhydrite and rock salt, but no more potassium salts are found above this.

It must not be thought that the layers of salt deposits are as sharply separated from one another as represented in the diagram; their general position is, however, as indicated, and after mining, the salts are roughly sorted out as far as possible before bringing them to the surface. Except in some cases where the potassium salts are used straightaway as manures, they have to undergo considerable purification before they are put on the market. This is effected entirely by wet processes.

Concentration and Purification. The salts are separated by careful recrystallisation in large tanks, and extensive chemical works for this purpose have been built on the site of the mines. Carnallite is the chief source of potassium salts of commerce. It is treated in tanks with a strong solution of magnesium chloride obtained in a previous operation. As potassium chloride is more soluble, the majority of this dissolves, and the residue left behind contains rock salt and kieserite (magnesium sulphate, $MgSO_4H_2O$). The soluble liquor containing the potassium salts is concentrated, and potassium chloride separates out, containing 25 to 30 per cent. of impurities. Many of these are removed by washing with cold water and a suitable process of recrystallisation, yielding eventually the pure chloride (or muriate) of potassium.



2. DIAGRAM ILLUSTRATING THE CONSUMPTION OF POTASH SALTS IN THE BRITISH ISLES

Kainite, another of the naturally occurring minerals, is a mixed sulphate of the following composition, $K_2SO_4MgSO_4MgCl_26H_2O$, and is worked up to remove the chloride. The mixed sulphates of potash and magnesia may be worked up for the manufacture of pure sulphate of potash or sold straight away for manurial purposes. The percentage of sulphate and chloride varies, but the potash is guaranteed 12·4 per cent. K_2O.

Potash in Agriculture. Although the manufacture of pure potash salts for various industrial purposes is of very great importance, the larger proportion of salts brought to the surface is used as manures after suitable treatment. In Germany, the seat of production, potash salts are generally used in the crude state, but it pays to purify or concentrate those salts destined for export. The consumption in Germany in 1905 amounted to some 514 lb. (reckoned as pure potash K_2O) per 100 acres of arable land; whereas in England it was 114 lb., in Scotland 341 lb. and in the United States 58 lb. The following is a list of the more important potassium compounds from Stassfurt used as fertilisers in this country:

Kainite, containing 12½ per cent. pure potash.
90 per cent. muriate of potash, containing 50 per cent. pure potash.
80 per cent. sulphate of potash, containing 48 per cent. pure potash.
Potash manure salts, a partially manufactured product, made in two grades, containing 20 and 30 per cent. pure potash respectively.

The varying proportions of *pure potash* contained in these "potash salts" is noteworthy, and should be taken into consideration by the agriculturist in determining the proportion of potash he intends putting on his land. In this country far more kainite is used than any other form of potash manure, something over 55,000 tons being imported into Great Britain in 1905, while muriate and sulphate of potash are in about equal favour, 3,000 to 3,500 tons of each being imported during the same period, and 6,000 tons potash manure salts. The consumption of potash in agriculture in this country is graphically demonstrated in the accompanying diagram [2].

The percentage of potassium salts should always be expressed as pure potash, as the farmer may be led astray by the contents of potash being made to look more attractive by being stated, say, as sulphate of potash, one part of potash being equivalent to 1·85 parts of the sulphate. The reader is referred to the excellent Board of Agriculture leaflet No. 72, which will be sent post free and free of charge on application to the Secretary, Board of Agriculture, 4, Whitehall Place, London, S.W. Letters of application so addressed need not be stamped.

Phosphatic Manures. The raw materials for the manufacture of these fertilisers consist of tri-calcium ortho-phosphate, $Ca_3(PO_4)_2$, in various forms, such as apatite, phosphorites, phosphatic rocks, and coprolites. The percentage of calcium phosphate contained in these substances varies considerably, Canadian phosphorite having 70 to 80 per cent., while phosphatic rock from districts on both sides of the Franco-Belgian frontier may contain as little as 20 per cent. The so-called "river" and "land" phosphates from South Carolina form one of the most important sources of supply, and carry 50 to 60 per cent. of calcium phosphate. Orthophosphoric acid being a tribasic acid, forms three calcium salts, the tri-, di-, and mono-calcium phosphates. The naturally occurring tri-calcium salt is an insoluble compound, and therefore not easily available to the plant. For manurial purposes it is converted into one or other of the two salts. Of these, mono-calcium phosphate or "superphosphate," is soluble in water and readily available. Di-calcium phosphate, although sparingly soluble in water, dissolves more readily in organic acids, such as citric, and in neutral salts. It is, therefore, more available than would at first appear.

Manufacturing Operations. For the manufacture of superphosphate, the mineral is ground up and treated for two minutes with sulphuric acid (chamber acid) in a lead-lined wooden tank provided with an agitator. The semi-fluid mass is then let down into a pit built of brickwork or concrete where the heat developed in the reaction raises the temperature of the mass to over 100° C., and a good deal of noxious gas is given off. The calcium sulphate formed in the reaction combines with the water to form a solid mass of plaster-of-Paris, so that the whole sets, and is dug out with pickaxes. The lumps are then reduced to powder in suitable machinery.

The value of the superphosphate is based on the percentage of "soluble phosphates," which will average 25 to 27 per cent., but will naturally vary with the raw material, and may be as high as 45 per cent. Superphosphate containing as much as 87 per cent. soluble phosphate is obtained by Packhard's process, which consists in extracting the soluble phosphate from the calcium sulphate with water and concentrating the liquor with further quantities of mineral rich in calcium phosphate. In this form superphosphate has considerable advantage over the ordinary brands, costing much less for carriage.

If the mineral is of poor quality, or otherwise unsuitable for conversion into superphosphate, it may be extracted with weak hydrochloric acid and then precipitated with lime, chalk, or some waste product, as calcium sulphydrate from alkali waste. In this manner the so-called "precipitated phosphates" are obtained, consisting of the "citrate soluble" di-calcium phosphate.

Bones, bone ash and basic slags are all phosphatic manures. Bones will vary in composition according to previous treatment [see Glues and Adhesives, page 5357]; they may be treated for the manufacture of "superphosphate" on the lines already described, or merely ground up (bone meal). The basic slag formed in the Bessemer steel process by the combination of lime with the phosphorus of the iron, and containing 10 to 25 per cent. of phosphoric acid (P_2O_5) has been largely used of recent years as a phosphatic manure. The phosphoric acid is not taken up by the soil unless the slag is finely ground, which is effected in ball mills [see Cement-Making, page 1583]. The ground material should not leave more than 20 per cent. residue on a sieve with 100 meshes to the lineal inch. In buying phosphatic manures the farmer must take the same precautions as mentioned under Potash Salts: 142 lb. of phosphoric acid yield 310 lb. of phosphate of lime, so, to convert phosphoric acid to phosphate of lime, multiply by 2·2. It looks more attractive to see that a manure contains 26 per cent. of phosphates as against 12 per cent. of phosphoric acid, but, as a matter of fact, these proportions are equivalent, both manures containing the same quantity of the active ingredient. [See Board of Agriculture leaflet No. 72, already referred to.]

Estimation of Phosphates. Calcium and magnesium phosphates present in phosphatic manures may be rapidly estimated by a volumetric process [see also Analytic Chemistry, page 4403].

Uranium salts react with phosphates to give a yellow precipitate of uranium phosphate. The uranium solution—say, uranium acetate—is added from a burette until a drop of the liquid gives a brown colour with a freshly-prepared, dilute ferrocyanide solution on a porcelain tile. The brown precipitate consists of uranium ferrocyanide and shows that the standard uranium solution is in excess.

The standard uranium acetate is prepared by dissolving 35 grammes with 25 c.c glacial acetic acid, and making up to 1 litre. This is approximately equivalent to ·005 gramme P_2O_5 in 1 c.c. It is accurately standardised against a solution prepared by dissolving 5 grammes of calcium phosphate, $Ca_3(PO_4)_2$, suitably purified, in dilute HCl, and making up to 1 litre. The "phosphate value" of the uranium solution is then accurately determined by titrating 50 c.c. of the phosphate solution with the addition of 10 c.c. of a sodium acetate solution. The liquid is heated nearly to boiling when nearing the end point of the titration. The estimation of the substance under examination is carried out on a quantity of material containing about the same amount of phosphoric acid, and under similar conditions to the standardisation experiment. The sodium acetate solution mentioned above is made from 100 grammes sodium acetate, 50 c.c. glacial acetic acid, making up to 1 litre.

Nitrogenous Manures. In the republics of Chili and Peru are extensive desert tracts where nothing grows but a little coarse grass round the margins of its salt pools. This is the Chili saltpetre district, whence sodium nitrate is exported in large quantities to Europe, to be used either in chemical works or as a nitrogenous manure for the land. The deposits known as "caliche" lie only a few feet below the surface and vary in composition. The main ingredients are sodium nitrate 20 per cent. or more, sodium chloride 50 per cent., and sodium sulphate 5 per cent., with smaller quantities of other salts, particularly sodium iodide. In consequence of this it is one of the most valuable sources of iodine. Large quantities of sulphate of ammonia [see Acids and Alkalies] are also used as manure. It usually contains 24·5 per cent. ammonia.

Farmyard manure contains much nitrogen, and also phosphates and potash. Guano, seaweed, and fish manure are all nitrogenous, but contain, in addition, various proportions of phosphates and potash.

Nitrogen is often expressed as ammonia, but this need not deceive anyone if it be borne in mind that 17 parts of ammonia are equivalent to 14 parts of nitrogen and 66 parts of sulphate of ammonia. The estimation of nitrates in Chili saltpetre is of considerable importance in the valuation of this substance as a manure, and as it has not been described under Chemical Analysis, we shall consider it here.

Lunge's Nitrometer. It is convenient to introduce at this stage a form of apparatus devised by Professor Lunge and much used in analytical processes where a gas is evolved and has to be measured. It consists of two glass tubes [3], a graduated "measuring tube," A, and a plain "compensating tube," B. Both tubes are connected together at the bottom by a strong piece of rubber tubing securely "wired" on. The tube A at the top is fitted with a stopcock, E, doubly bored with slanting holes, so that the space in the tube may be connected either with the cup C or the outlet tube D, according to which way the cock is turned. Mercury is poured into the limb B till it about two-thirds fills both tubes, the cock E being set so that the interior of A is in communication with the air outside. The whole apparatus is supported on a suitable stand, which allows the tube B to be raised or lowered independently of A. On raising B the mercury will flow out of it into the tube A—in other words, the mercury will rise in A, driving out the air through the cock. On shutting the cock as soon as A is full of mercury, no air can be drawn in, even although the mercury in A tends to sink by the action of gravity on lowering B again to its former

3. LUNGE'S NITROMETER

position. On connecting D with the vessel containing the gas to be examined and carefully opening the cock in the reverse direction to that shown in 3, the mercury in A will sink, drawing the gas in with it. On shutting the cock and adjusting the tube B until the level of the mercury in both limbs is the same, we can now read off the volume of the gas we are about to examine at the temperature and pressure of the atmosphere. [For the influence of temperature and pressure on the volume of a gas, see course on PHYSICS.]

Operating the Instrument. We now, perhaps, require to bring the gas into contact with a liquid which will absorb one of its constituents without affecting the others. Suppose our measured volume of gas to be a mixture of air and carbon dioxide, and that we wish to determine in what proportions they are present. Pour into the cup C a small quantity of strong caustic soda solution, then lower the tube B, and by carefully turning the cock to the position shown in 3 allow some of the caustic liquor to be drawn into the tube A, being careful to shut the cock before any air is sucked in. Gently agitate the liquid and gas in A, by raising and lowering B, thereby compressing and expanding the gas in A and covering the interior walls with a thin layer of caustic liquor, and so exposing fresh surfaces to the action of the gas. The measuring tube may also be unclamped if necessary, and the mercury shaken up with the caustic liquor and gas, but this operation requires care. When the action is believed to be complete, adjust the levels in the two tubes again, and read off the volume of the gas, which will now be smaller than it previously was by the volume of dioxide absorbed. Gentle agitation of liquid and gas should be repeated, and on again measuring the volume the same figures should be obtained as before, showing that absorption of the carbon dioxide gas was complete.

Nitrates. Salts of nitric acid are decomposed with strong sulphuric acid, when a mixture of the two are shaken with mercury, the whole of the nitrogen being converted into nitric oxide, NO. All that is necessary is to carry out this operation in the nitrometer just described, and to measure the volume of the gas in order to determine the amount of nitric acid (N_2O_5) in the substance analysed.

Proceed as follows: Weigh out such a quantity of the substance that the gas evolved will be easily contained in the graduated portion of the tube. To obtain an idea what quantity this will be, it may be stated that every cubic centimetre of NO evolved corresponds to 2·4 milligrammes of N_2O_5, so that ·38 gramme of sodium nitrate or ·45 gramme of potassium nitrate will yield 100 c.c. of gas. Run the mercury up the tube A until it passes through the cock E and just begins to enter the cup C. Close the cock, and place the weighed substance in the cup, with a small quantity of water to dissolve it. By lowering tube B, and gently opening the cock, draw the liquid on to the top of the mercury in A, but be careful to see that no air enters. Add a little more water to wash out the cup, and draw this into the measuring tube. 1 or 2 c.c. of water should suffice to get the whole of the substance into the tube. Then pour 15 or 20 c.c. of *pure* strong sulphuric acid into the cup, and draw this into the measuring tube, close the cock, and, unclamping the tube A, shake vigorously the mixture of liquids at the top so that the surface of the mercury is broken up into globules, which mix in with the acid. Set aside one hour to stand, then adjust height of mercury in both tubes, and read off the volume of gas, from which may be calculated the percentage of nitric acid on the basis of the figures already given. Allowance must be made for the fact that sulphuric acid is not so dense as mercury, and requires a column six and a half times as high as the latter if both are to balance.

Other Uses of the Nitrometer. This instrument can be used for estimating nitrites as well as nitrates, each cubic centimetre of NO being equivalent to 1·7 milligrammes of N_2O_5. It is also used a good deal for measuring the total nitrogen in "nitrous vitriol" [see Sulphuric Acid, page 4627]; also for the estimation of urea and ammonium salts. This requires a little further explanation. Instead of using sulphuric acid to effect the decomposition, its place is taken by a strong solution of sodium hypobromite, which liberates all the nitrogen, whether in urea or ammonium salts, in the form of the gaseous element itself:

$$CO(NH_2)_2 + 3NaBrO = CO_2 + N_2 + 2H_2O + 3NaBr.$$

Every cubic centimetre of nitrogen is equivalent to ·002952 gramme of urea. In addition to these the nitrometer can be used for the estimation of nitrates and nitrites in water and in a number of other analyses which would lead too far to go into here.

Nitrogen from the Air. The atmosphere surrounding us contains roughly four-fifths of its weight of nitrogen. We have, therefore, an inexhaustible supply of nitrogen, if only an economical method could be found for converting it into nitrates or other nitrogenous compounds suitable for manure.

The manufacture of compounds of nitrogen from the air by electrical processes has recently made great advances. Two processes are working on a fairly large scale; one of them converts the nitrogen into basic calcium nitrate, and in the other the nitrogen is obtained in the form of cyanamide. Both these substances are said to be suitable for direct application to the land.

The cyanamide process is due to Drs. Frank and Caro. It consists in passing nitrogen over calcium carbide heated to a high temperature. The substance obtained has the formula $CaCN_2$. Calcium carbide is at present manufactured in considerable quantities for the production of acetylene gas for lighting purposes. The nitrogen is obtained from the air by liquefying it and distilling the liquid. The second method is merely a manufacturing adaptation of the observations originally made by Cavendish (1784), who found that nitrogen and oxygen combine slowly to form oxides of nitrogen under the action of electric discharges. The conditions applied in practice depend upon the fact that "the yield is notably increased when the electrodes are placed in a narrow part of the chamber in which the reaction takes place, in order to submit the whole of the gas to the action of the electric energy, and to draw off as rapidly as possible the gases which have been subjected to this action." (Guye.)

Experiments are in progress or small plants erected for working this process in Norway (Eyde & Birkeland), at Freiberg in Switzerland (Kowalski's method), and at Niagara Falls (Bradley-Lovejoy method). The gases obtained in the arc furnace chamber contain 1 to 2 per cent. by volume of nitric oxide, the remaining 98 per cent. or so consisting of inert gases. The problem of separating this large dead weight of inert gas economically is no easy one. By cooling the nitric oxide gas, it is converted into N_2O_3 and N_2O_4, which, by reaction with water and an alkaline solution such as lime water, yield nitrate of lime.

Group 12
MECHANICAL ENGINEERING
39

Continued from page 5456

By JOSEPH G. HORNER

Many of those who have followed the course on Mechanical Engineering, and who, perhaps, have approached the subject for the first time, may have received the impression that, where so large a number of departments and highly technical subjects are involved, there must be inevitable isolation from one another. It seems a far cry from moulding to machine tools, from pattern-making to metal-turning, from milling to forging, from the work of the draughtsman to that of the boilermaker and plater. That is true in one sense. But we want now to show in a final article the *unity* of engineering practice, the underlying and essential relations which exist between trades and subjects so diverse. We shall show how the heterogeneous and extensive elements make up an organic, unified system, with all of which the true engineer must be familiar. We ask our readers, therefore, to accompany us through a few typical engineers' works, and to see how the great organisation is laid out and carried on. Then we shall see in what manner the requisite training is obtained, and how the ambitious youth is started on his enthusiastic career. For there is little chance of high success in engineering for those who have no love for the pursuit.

Machines and appliances are found in every department of engineering without exception, and are much more numerous in some than in others, but are nevertheless ubiquitous. They are the key to economic production, for success or failure in general depends more largely at the present time on the utilisation of the most suitable machines out of several possible than on any other single factor. And the secret of successful organisation is to so arrange these machines and appliances, and the several shops and departments in which they are located, in the manner which is best calculated to ensure their most economical operation from the point of view of *output.* And these questions of arrangement, location, organisation, it must be remembered, lies wholly outside that of the selection of the machines and methods most suitable to produce given results on individual pieces of work.

The Units. A modern engineer's factory, employing a small army of men, ranging from, say, 500 upwards to 2,000 or 3,000, spread over several acres of ground, containing a number of different shops [see page 2108], with appliances, tools and machines that number some thousands, requires good generalship. Every shop and every sub-department of the works is a unit distinct and separate in itself, a little world of its own, a complete microcosm. But it is, nevertheless, linked with every other shop and department in the vast works, and this is the point of view from which it has to be regarded in the offices. The work in every department must be kept moving relatively to that in every other, though the men in the various departments never intermix with or seldom speak to those in other departments or have any knowledge of what is being done elsewhere than in their own. But the management knows, and has to regulate the progress and sequence of operations so that all the individual sections of machines and structures will come into the erecting, or assembling, or store, or shipping department at the right time. This explains the apparent marvel of the erection of a bridge, or the building of a locomotive or a crane, or the equipment of a central station or a new factory in what seems an incredibly short space of time. It explains why a firm can turn out a complete engine every day, or a hundred sewing machines or typewriters in a week, and so on. The secret is arrangement, organisation, management, with all that is covered by those comprehensive terms. Let us consider these in turn.

Arrangements. By the word *arrangement* is understood the laying out of the various isolated shops and the best method of linking them together. This matter, highly desirable though it is, has not received general attention until within the last ten years or so. Everyone who is at all familiar with factories can call to mind scores of old works laid out without any regard to economical inter-communication between the units—the shops. Upstairs and downstairs, and a shop here and another yonder, with nothing but rough, dusty, or muddy yard between, encumbered with the wasters and rubbish heaps of a generation—that is the old style, in which a vast amount of time, which is money, is wasted within and without the shops in the mere hauling of heavy materials and work about by human muscle: often, too, backwards and forwards over the same ground, or up and down old stairs. Central control is largely lacking, and men do to a large extent what seems right in their own eyes.

But the modern style is this—shops arranged in parallel or at right angles, and located so that the cost of haulage is reduced to a minimum. The shops are arranged as much as possible in the same sequence as that of the course of the work. Raw materials come in at one locality, and the work in its progress moves onwards towards the final departments in which it is delivered completed. A system of narrow-gauge tracks—*light railways*—traverses the shops, and also connects all the shops, one with another adjacent. Turntables, and curves are fitted where necessary, and weighbridges lie in the course of the tracks at the place of entry and of delivery. Besides this, there is a system of hoisting apparatus in all the shops where heavy work is hauled—as in the foundry, the boiler shop, the turnery, and the machine and erecting shops. It comprises overhead travelling cranes spanning the entire width of a shop, and ranging anywhere between 5 tons and 100 tons capacity, varying with the mass of the work to be handled. It comprises swinging jib cranes ranged along the walls, to command certain areas, to cover certain machine tools, or foundry areas, or a smiths' forge, etc. It also includes overhead tracks for suspended hoists, which are run along over the floors, or machines, to deal with a class of work too heavy to be lifted by hand, yet not heavy enough to require the services of the big cranes and travellers. To operate these cranes and various machines there are power installations. In a big modern factory there are generally four distinct power sets—steam, electricity, water, and compressed air.

Steam Power. The steam power of a works is not used for driving machine tools directly to the extent that it was a few years since. Its principal functions now are the driving of shop shafting and the supply of power to the dynamos for driving and lighting. Many independent machines that were formerly steam-driven, such as punches and shears, now have motors fitted. Many cranes formerly actuated by steam have been thrown out to make way for electric cranes. There is still, however, in many works a large number of machines and cranes that are steam-driven, besides the main shafting. The boilers generally used are of the Lancashire or Galloway type, though in many recent plants water-tube boilers of Babcock and Wilcox, or similar type, have been installed in preference [see Prime Movers].

Electricity. Electricity is without doubt the power agency which is destined to overshadow all others in factories, as elsewhere. Already many factories use electricity to drive shafting, or even abandon shafting for an individual motor drive to

Compressed Air. Compressed air, the youngest of the [illegible] power agents, is also one that is very promising. Atmospheric air is compressed by a steam engine in a cylinder, usually to 80 lb. per square inch for factory service, and delivered at that pressure into a receiver resembling a vertical boiler in external appearance, and thence delivered to hoisting machines, to machines for riveting, chipping, caulking, hammering, machine moulding, and much beside. In the early days of compressed air, difficulty was experienced consequent on the elasticity of the medium, which produced jerky movements, difficulties due to heating and condensation, to wear of the valves, and to other mechanical details. These have been overcome, and air-operated tools and appliances are reliable. There is the objection to piping as in steam and water supply, but in some machines there is little rivalry even with electricity in the field. In chipping, caulking, hammering, sand blasting, compressed air has the field all to itself. The tiny engines and their mechanisms are marvels of design [see page 5455]. Only in light hoisting does electricity come into close rivalry with air, and that only since air has spread itself over this promising field. In all overhead track systems, the rivalry now lies practically only between two kinds of hoisting machine—the air-operated, and the electrically-driven travelling hoists.

the lifting hook is being ousted in favour of the lifting magnet. Steam boilers and engines are required still, but the boilers that supply the power house are generally of water-tube type, and the engines are of high speed or high rotative speed type, coupled directly to dynamos.

The great advantage which the electric drive has over a system of steam pipes is the absolute flexibility of the electric conductor by comparison with the rigid steam pipes, with the condensation of steam therein—always an ever-present trouble. Many cranes and machines have their own independent boiler, but these are suitable only for outdoor work, as in yards, being intolerable in closed shops. An incidental point in favour of electricity is that a plant is required to supply light in any modern works, and the same, or a duplicate plant, can be used for power.

Water Power. There are certain operations in which the power of water, used at a pressure which ranges between 750 lb. and 1,500 lb. per square inch, holds a place that seems to be secure against the rivalry of the other power agencies. Whenever massive forgings have to be squeezed and shaped, or large steel plates flanged or bent, or heavy moulding machines pressed, or other operations of this general character performed there is no agent so reliable as pressure water. All works, therefore, which do massive forging and boiler work, heavy moulding by machine, forcing on of wheels over their axles, or machine riveting, must have a hydraulic pressure plant. This comprises engines and force pumps, accumulators and a system of very strong pipes with special joints to convey the water to the various machines. Formerly the same power was often used for the heavier fixed cranes about a works, and is so still in numbers of cases. But in laying down new installations, preference is now given to electricity for crane service, retaining, however, the hydraulic system for the duties just now specified.

the shops, and in

the shops, should obviously be made to conduce to economies in output. The old style was, generally, storied buildings, because the old shops mostly grew up in the heart of cities. As businesses were of slow growth, and space was limited, makeshifts were unavoidable, and this explains why the older shops, even those of the leading firms, are generally anything but modern in their arrangements. Heavy and light machines are grouped together instead of being separated, and upper floors are loaded with heavy machines that ought to be on the ground floor. In consequence of these difficulties many of the older firms have migrated to suburbs, built themselves new shops, and spread themselves out with room for future growth.

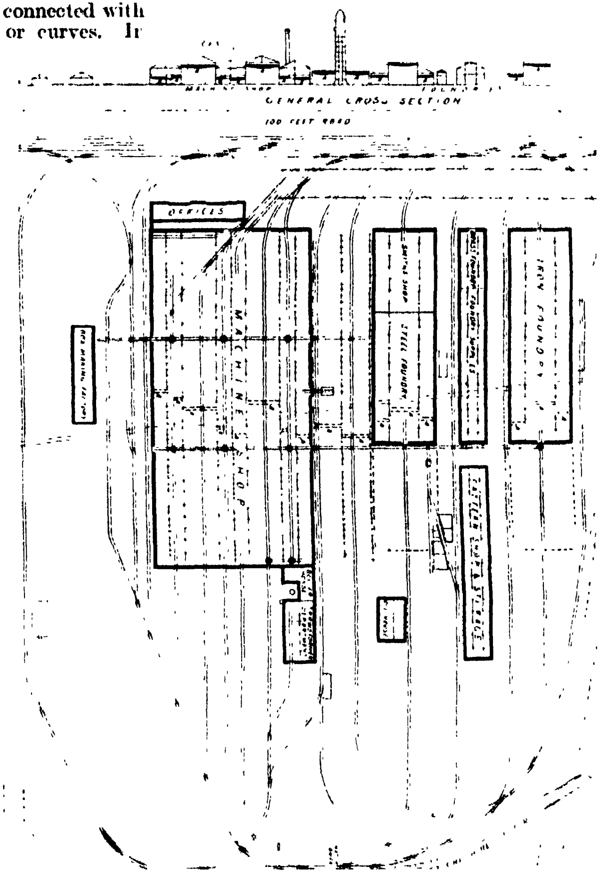
Buildings. Factory buildings may be grouped under two classes—the single-floor building, and the storied building. The former is suited for heavy machinery and massive operations; the latter for the lighter industries. The former is necessary in foundry work, forging, boiler-making, plating, bridge and girder work, in the construction of all massive machine tools, engines, cranes, and the heavier dynamos and motors. The latter is suitable for light brass work, as the manufacture of cocks, valves, gauges, pitch chains, and wheels, small mechanisms, sewing machines, typewriters, electrical apparatus, and so on.

But in nearly all factories there are heavy and light departments. There are light machine tools, bench work, assembling, fitting. Hence, we find that most factories have work on the ground floor, and work on upper floors, heavy and light respectively. Hence, a common type of building is that with a wide central bay, clear up to the roof, flanked with side bays, each with an upper floor. Or alternatively, side galleries are erected in the main building, still leaving the central area open to the roof. For most engine work these are the most approved arrangements. If the shops are so large that one bay is not sufficient, then the bays are simply repeated: two, three, or more, all alike, and running parallel with each other. It is not necessary to separate these with walls if they belong to a single shop, as a moulding floor or a machine shop, but the pillars which support the [illegible] principals are the only essentials present. [illegible], the view within these large shops is simply [illegible] of a very large rectangular area, with a few [illegible] of columns surmounted with girders erected [illegible] carry the roof principals. Each bay has [illegible] own separate sets of overhead travellers, cranes, and floor tracks, the latter connected with the shops adjacent by turntables or curves. In these shops the heavy machines are grouped by themselves, and the light ones in a separate area. Heavy lathes will occupy one department, where they can be served with heavy cranes, and light ones elsewhere; and so of other machines, as grinding, and gear cutting, and automatics, which are relegated to distinct areas. In foundries the machine moulding department will be kept wholly apart from the hand moulding. Floor work will be separate from bench moulding, loam from greensand, core making from moulding, etc.

Light. An essential in a shop is ample light, in which the old shops were sadly deficient. A shop open to the roof can be lit from the roof without any windows at the sides, though it is usual to include the latter. A continuous skylight is generally run along each side of the ridge. The *saw-tooth roof* is becoming more common, the idea being borrowed from the weaving sheds. Here direct sunlight is avoided, yet there is ample illumination.

Ventilation. The principles of ventilation and heating have been more honoured in the breach than in the observance. In modern works both are regarded. In the floor shops, open to the roof, a set of louvres along the ridge generally suffices for ventilation. Heating is more difficult. Heating by hot water on the low-pressure system is becoming usual. Some systems now combine heating with ventilation [illegible] ing with ventilation the technical facts of [illegible] adopted only in of the public are prejudiced [illegible] as yet. have not both sides alike. It is [illegible] tory is found too much on the observat-in [illegible] f old. opaque, [illegible] accommodation is [illegible] in many works, reading-rooms, libraries, and in a few instances technical schools, so that the younger race enjoy much greater privileges than their predecessors did.

Plans of Typical Works. Figure 1 illustrates one of the best laid out works in England, built at Trafford Park, Manchester, by the British Westinghouse Electric and Manufacturing Co., Ltd. The parallel lay of the shops, and the perfect intercommunication between them all, with the Cheshire railway lines, with the road, and with the Bridgwater Canal are the noticeable points in the plan arrangements. There is room for extension endwise of the steel and iron foundries, and in a lesser proportion of the other shops. The relative areas of the shops may be noted, as they are fairly typical. The machine shop is by far the largest, as it usually is in most engineers' works. It measures over 900 ft. in length, by 427 ft. in width, and covers between nine and ten acres. This vast width is divided into five bays, not, however, separated by walls, but by columns which permit of an unobstructed view. In fact, the buildings are steel skeleton-like structures on which all the loads of roof and cranes are carried, and the brickwork is merely a filling in to form walls.



1. TYPICAL ARRANGEMENT OF ENGINEERS' WORKS
(British Westinghouse Electric and Manufacturing Co., Ltd.)

Every shop where heavy work is done is served by tracks, which total to about ten miles in length. But then the area covered by the buildings amounts to 30 acres. The tracks are not, as is usually the case in works, of 18 in. or 24 in. gauge, but standard 4 ft. 8½ in. so that goods trains run into the shops when required to load or unload materials and manufactured goods. Where the tracks cross at right angles, turntables are used; elsewhere curves of 200 ft. radius predominate.

The ground floor and the two-storey and galleried types are represented here [see the general cross section]. In the machine shop two of the bays are open to the roof, and three are two stories high. The lighter electrical work is done here, largely by girls. The foundries are open to the roof. The iron foundry is 600 ft. long by 180 ft. in width. The brass foundry is 170 ft. long by 75 ft. wide. A number of powerful overhead travelling cranes serve the shops. These are indicated by the letters AA in the plan and general cross section. Most of them are of 50 tons power.

Another excellent lay-out is shown in 2, that of the works of the British Thomson-Houston Co., Ltd., Rugby. Here, two systems of tracks are employed. There is the standard 4 ft. 8½ in. in connection with the main line railway, and the "Hunt" system of narrow-gauge tracks serving the shops. The system is a most complete one, with turntables, crossovers, curves, switches. The drawing is self explanatory.

Sections. Figure 3 gives a section through four bays of the machine shop of Kendall & Gent, Ltd. The two middle bays are open to the roof, the two flanking ones are two-storied buildings, and both the ground floor and the upper one carry light machines. The floor which seems to cover the middle bays is not so, but an end gallery only.

The most approved method of supporting the roofs and the travelling cranes away from outer walls is here seen. Steel columns, lattice-braced, afford support to the roofs and the traveller runways, generally also to bearings for shafting. The columns leave free communication between bays. If a separation is required the spaces between the columns can be bricked in. But the brick filling carries no weight. This method is often adopted for outside walls. Steel columns carry the roof, and the spaces between them are bricked up.

Organisation of a Works. This phrase signifies the system by which the work of the various shops and departments is executed. It includes the commercial and the mechanical side, two very distinct groups which are seldom controlled by the same chief, or the same staff. Each requires knowledge and experience of a totally different kind from that of the other. Financing and manufacturing are as opposite as the Poles, but both are essential to the successful conduct of a business.

In the organisation of a factory, complete account has to be taken and recorded in the offices of all orders, the labour costs, the materials used, the prime costs due to all charges and expenses, the interest on and depreciation of capital, and the value of the assets. This entails an immense commercial system altogether apart from the tasks of actual labour. Of late years much more attention has been paid to the details of cost-keeping than formerly, and this has been favoured by the growth of the simple card system in place of cumbrous account-books. The work of the shops has to be preceded by estimates and tenders, by designs and drawings, after which the work is carried out under the supervision of managers and foremen.

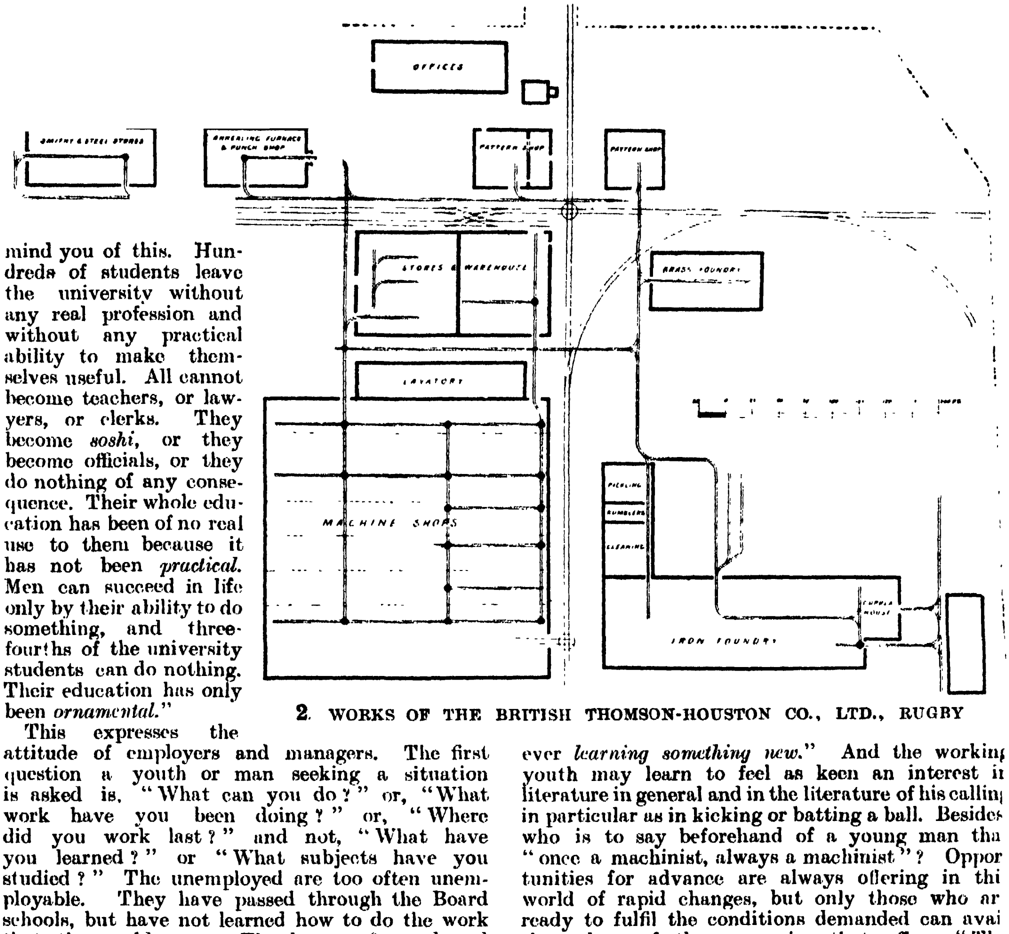
The Management of a Works. After a factory has been laid out and organised, the duties of the managers are supposed to proceed within specified limits. Latitude and initiative are allowed and often encouraged, but not such as would interfere with the general organisation laid down. Thus, a manager or foreman is perfectly free to use his judgment in regard to varying the methods which have been hitherto adopted in the shop of which he has charge, but in doing so he must not interfere with those of another department that lies outside the sphere of his responsibility, and he must not do anything that would check the progress of the work. Any radical changes can emanate only from, or be sanctioned by, the general manager, or the managing director, who has supervision of the entire factory. Experience shows that undue interference with the heads of departments is injudicious. The best results follow when a free hand is given, subject to the above-named necessary limitations; to give a man responsibility, and to judge and pay him by results is the sure way of getting the best out of him.

The Training of Engineers. The training of engineers and craftsmen is a question around which much controversy has been aroused in connection with the growth of the technical schools, and the increase in the unemployed in our streets.

The man who seeks success, either in the conduct of mechanical engineering works or in the practice of one of the separate crafts of the factory, can achieve it only by a combination of manual work and study. No man, however skilful he may be, or however excellent his opportunities of acquiring knowledge and experience may have been, can neglect without serious loss the recorded experience of others. To test it, write articles or letters to a technical journal stating how you have done certain pieces of work, and other readers will show you different, and perhaps better, ways of doing the same job. It is the same in visiting other shops, or in conversation with other men. The more you do in this way the less conceit will you have of your own acquirements. The greatest engineers are generally omniverous readers, and are discreetly modest.

Technical Education. The technical education of the schools cannot be kept out of the subject we are considering. Though the old engineers did without it, they would nevertheless have been spared many initial difficulties could they have stated them to a qualified teacher. The present danger is lest the place of technical training should be overrated. It must not be regarded as a kid-gloved, genteel device for creeping into engineering by avoidance of hard work. In that way lies certain failure. Successful engineering is not to be achieved by the cramming of facts from books and teachers. Facts, like tools, are of no value unless skill in their employment is acquired, and that is what the youth gathers in the shops. Hence the proper place of technical education is as an *aid* to the shops, not preceding or following, but *sandwiched in* with shop practice. But here the difficulty arises, because there is only one way to accomp written mainly by work in the shops in th "Machinery" resembles or to spend six sum eaters for the engine builders winter term in ineering is treated popularly in exclaim that thi onthlies, "Cassier's Magazine," Yes; and any y ineering [illegible] and influence, means to rise ab ruck, must do so. The youth who gives his [illegible] to dissipation, and turns up sleepy and silly in the morning, burns his candle thus; then why should the youth with noble ambitions grumble? The life stories of the great engineers, in common with others, teem with records of men of whom it is literally true: "But they, while their companions slept, were toiling upward in the night." A passage in the "Life and Letters of Lafcadio Hearn" applies exactly to the present subject. He says (vol. 2, page 164):

"Science is difficult, really difficult; but everything worth having in this world is difficult to get exactly in proportion to its value. The only question, I think, should be, 'What study will be most useful to me all through life?' but not whether it is difficult. What is important to know is always difficult to learn. And I would remind you of this. Hundreds of students leave the university without any real profession and without any practical ability to make themselves useful. All cannot become teachers, or lawyers, or clerks. They become *soshi*, or they become officials, or they do nothing of any consequence. Their whole education has been of no real use to them because it has not been *practical.* Men can succeed in life only by their ability to do something, and three-fourths of the university students can do nothing. Their education has only been *ornamental.*"

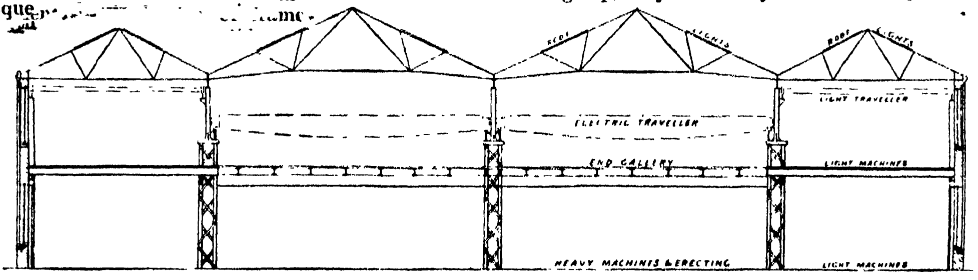


2. WORKS OF THE BRITISH THOMSON-HOUSTON CO., LTD., RUGBY

This expresses the attitude of employers and managers. The first question a youth or man seeking a situation is asked is, "What can you do?" or, "What work have you been doing?" or, "Where did you work last?" and not, "What have you learned?" or "What subjects have you studied?" The unemployed are too often unemployable. They have passed through the Board schools, but have not learned how to do the work that the world wants. The hewer of wood and the drawer of water whose sole capital is brute force has been displaced by the tireless machine. But the supply of skilled men is not equal to the demand.

[illegible] The question has often been asked. the technical facts [illegible] ftsman expect for a course of the public are prejudice[illegible] ruly pointed out that have not both sides alike. It [illegible] be[illegible]n manual workers found too much on the observa[illegible]in[illegible] ie the inducement opaque [illegible] me [illegible]

to study does not seem very attractive. Perhaps not, from the purely utilitarian point of view. Yet of old it was said, "Is not the life more than meat?" Though men may be poor, they can be of Nature's nobility. "Men, my brothers, men the workers, ever *learning something new.*" And the workin youth may learn to feel as keen an interest i literature in general and in the literature of his callin in particular as in kicking or batting a ball. Besides who is to say beforehand of a young man tha "once a machinist, always a machinist"? Oppor tunities for advance are always offering in thi world of rapid changes, but only those who ar ready to fulfil the conditions demanded can avai themselves of the vacancies that offer. "Th readiness is all." Moreover, the zest of life is no always felt so much in the success as in the struggles There is joy in the battle, even though the final not of victory may not be heard. Therefore we say ther is every reason why the youths in our shops shoul avail themselves gladly of all opportunities o increasing their knowledge by study, in season an out of season. Certainly, even if competence elud their grasp, they will rarely be "out of a job."



3. SECTION THROUGH MACHINE SHOP (Kendall and Gent, Ltd., Manchester)

Apprenticeship. In all departments of engineering the knowledge of the craftsman can be acquired only by apprenticeship, or its equivalent. By this is meant going through the same duties as those of the apprentice for a term of years, but without the indenture. That is how most of the lads are now trained. The difference is only in name, and in the fact that the period of tuition is terminable on either side at a moment's notice. This, however, happens only when the relations prove unsatisfactory. The trade is learned just as in apprenticeship; periods ranging from three to five, or seven years are passed through, and wages are paid.

Though this holds good of all the great departments of engineering, exceptions are growing up. Apprenticeship or its equivalent is adopted in pattern-making, moulding, forging, boiler-making, plating, turning, fitting, and erecting, and to a limited extent in the machine shop. But in some departments of this shop and of others the growth of machines of some types has had the effect of displacing skilled craftsmen. It is so in the practice of the automatic screw machines, of die forging, of moulding machines. These departments are growing, but as yet they do not very seriously assail the position of the skilled craftsman.

Articled Pupils. Articled pupils are the so-called "gentlemen apprentices," who pay premiums ranging from £50 to £100 a year for the privileges of enjoying the training afforded by going through the entire course of the works departments, including the drawing office. Sufficient knowledge is gathered in the shops for an intelligent understanding of the operations performed, without much manual skill. Many, however, do acquire a considerable amount of this. But the extent of the field which has to be covered prevents a lengthy stay in any shop. The work of design gathered in the drawing office is of greater importance, and a good scientific and mathematical training are essential here. Pupils are brought into intimate relationships with the principals or the management, and so may learn much. They are also sent out on contracts in charge of erections, and thus acquire practical knowledge. They also witness tests, and may have to assist at them. There are not wanting indications that pupilage may become an institution of the past, and apprenticeship on a broad basis take its place. That is so now in a few isolated works, and it may be expected to extend.

International Rivalry. A generation ago English engineers were in the proud position of being able to ignore the trade rivalry of foreign nations. British machinery was in great demand, and British engineers and workmen were sent abroad to teach the foreigner how to design and build mechanisms. That state of things is past, and now many of our own shops are equipped extensively with machine tools of German and American manufacture. The designs and systems also in use in those countries have been imitated here. The impress of American design is apparent in many British-made tools for turning, planing, grinding, milling, gear cutting, and measurement. Very often these tools are much better, stiffer, stronger than their prototypes, but their development has been nevertheless clearly due to American influence. Ten years ago the British firms began to wake up, and copy and improve; now they enter into rivalry with their teachers. It is the same in the lay-out of works, and in the altruistic aspect of the provisions made for workmen. The modern types of wo[illegible]s illustrated in this article are an innovation, the first developments of which grew in America. The interchangeable system also, to which reference has been frequently made in this course, is of American development. But it is now adopted in hundreds of British and German firms, for Germany, like ourselves, has borrowed from America.

Briefly, the issue now is that the three great manufacturing nations of the world have arrived at a period of intense rivalry. In a lesser degree, though only by comparison, the same holds good of the engineering products of Belgium, France, Italy, and Switzerland.

The Key to Success. Under these conditions the question of how to maintain a good industrial position — the time to talk of *supremacy* is past—becomes one of national importance. Clearly the solution lies mainly in the training of a race of capable engineers and skilful and contented artisans. How best to do this is answered in different ways. In England and America it is done mostly by a practical training in the shops, through indentured or non-indentured apprenticeship; and in the case of articled pupils, of going through the works. In Germany, technical training occupies a large and essential place. Military service also is stated to exercise a steadying effect, and to engraft habits of obedience and precision on the army of labour. The technical training is certainly reflected in the designs of many German machines in respect of the most economical disposition of materials, though this is sometimes cut too finely. Putting it very broadly, the differences in English and German design may be stated thus: that experience largely controls the first, and mathematical calculations the second. The first savours distinctly of the shops, the second of the schools. The difference is reflected in the technical literature of the two countries. English books are mainly practical; we have no original works corresponding with those of Reuleaux. American mechanics are not so hide-bound by the traditions of apprenticeship as the English are. The "one man one job" idea is not so rampant. Initiative is encouraged. Consequently the American has a chance if he is prepared to grasp it. His application is more intense, but he does not wear so long.

Technical Literature. The technical literature of engineering is rapidly becoming cosmopolitan. English journals are read abroad. They take the highest rank. "Engineering" and "The Engineer" are very solid, reliable, and representative, and are second to none in the world. The "Mechanical World" is mainly a workman's paper, and is very practical. The "American Machinist" is now known nearly as well over here as in the States. Its name exactly expresses its scope. It caters for the men in the shops, and is written mainly by workmen for workmen. "Machinery" resembles it closely. "Power" caters for the engine builders and users. Engineering is treated popularly in two excellent monthlies, "Cassier's Magazine," and the "Engineering Review." The articles are technically accurate, mostly written by and up-to-date. There are, of course, other journals and magazines, but those are the best. "The Foundry" (American) is devoted entirely to the moulder's craft. "Wood Craft" treats of various woodwork, including pattern-making; this is also American. The German journal "Zeitschrift des Vereine-deutscher Ingenieure" is the leading one in that country. Another excellent one devoted to machine tools is the "Zeitschrift für Werkzeugmaschinen und Werkzeug." "Stahl und Eisen" deals with foundry and metallurgical work. The "Revue Industrielle" is one of the best French journals.

THE BEST BOOKS ON MECHANICAL ENGINEERING

Steam and Steam Engines. “Steam,” by Ripper (Longmans, Green & Co., London. 2s. 6d.); “Steam Engine Theory and Practice,” by Ripper (Longmans. 9s.); “The Marine Steam Engine,” by Sennett and Oram (Longmans. 21s.); “A Manual of Marine Engineering,” by Seaton (Charles Griffin & Co. Ltd., London. 21s. net); “Marine Engines and Boilers,” by Bauer (Crosby Lockwood & Son, London. 25s. net); “The Steam Engine,” by Holmes (Longmans. 6s.); “Valves, and Valve Gearing,” by Hurst (Griffin. 10s. 6d.); “A Manual of the Steam Engine and Other Prime Movers,” by Rankine and Donkin (Griffin. 12s. 6d.); “Steam and Steam Engines,” by Jamieson (Griffin. 10s. 6d.); “The Practical Engineer's Handbook,” by Hutton (Lockwood. 18s.); “Text Book on the Steam Engine,” by Goodeve (Lockwood. 6s.); “A Handbook on the Steam Engine,” by Haeder and Powles (Lockwood. 7s. 6d. net); “The Safe Use of Steam,” by An Engineer (Lockwood. 6d.); “The Steam Engine,” by Cotterill (E. & F. N. Spon, Ltd., London. 15s.); “Theory of Heat,” by Clerk-Maxwell (Longmans. 4s. 6d.); “The Indicator,” by Pickworth (Emmott & Co., Manchester. 3s. net); “Indicator Practice,” by Hemenway (Chapman & Hall, Ltd. 8s. 6d. net); “The Indicator,” by Porter (Spon. 9s.); “Slide Valve,” by Welch (Spon. 6s.); “Slide Valve,” by Halsey (Spon. 6s. 6d. net).

Steam Boilers. “Marine Boiler Management and Construction,” by Stromeyer (Longmans. 12s. net); “Steam Boiler Construction,” by Hutton (Lockwood. 18s.); “The Heat Efficiency of Steam Boilers,” by Bryan Donkin (Griffin. 25s.); “Boilers, Marine and Land,” by Traill (Griffin. 12s. 6d.); “Steam Boilers,” by Munro (Griffin. 4s. 6d.); “Steam Boilers, Their History and Development,” by Powles (Archibald Constable & Co., Ltd., London. 24s. net); “Water Softening and Treatment,” by Booth (Constable. 7s. 6d. net); “Smoke Prevention,” by Booth and Kershaw (Constable. 6s. net).

Gas Engines. “Gas Engines, and Producer Gas Plants,” by Mathot (Lockwood. 12s. net); “Gas Engines,” by Robinson (Spon. 21s. net); “Gas, Gasoline, and Oil Engines,” by Hiscox (Constable. 10s. 6d. net); “The Gas and Oil Engine,” by Clerk (Longmans. 15s); “Gas, Oil. and Air Engines,” by Bryan Donkin (Griffin. 25s. net); “Modern Gas and Oil Engines,” by Grover (Technical Publishing Co., Manchester. 4s. 6d.).

Fuels. “Liquid Fuel and its Combustion,” by Booth (Constable. 24s. net); “Producer Gas,” by [illegible] the technical facts o[illegible] 10s. 6d. net); “Gas, Oil, of the public are prejudice[illegible]owes (Constable. 6s.); have not both sides alike. It [illegible] (Whittaker, London. found too much on the observa[illegible] [illegible]er Analysis,” by opaque [illegible] “Oil Fuel,” by [illegible] (Griffin. 5s. n[illegible]; “[illegible]me Petroleum,” by Redwood (Griffin. 2 vols.).

Steam Turbines. “The Marine Steam Turbine,” by Sothern (Whittaker. 6s. net); “Steam Turbine Engineering,” by Stevens and Hobart (Whittaker. 21s. net); “Steam Turbines,” by Stodola (Constable. 21s. net); “Experimental Researches on the Flow of Steam through Nozzles and Orifices,” by Rateau (Constable. 4s. 6d. net); “The Theory of the Steam Turbine,” by Jude (Griffin).

Automobiles. “English and American Steam Carriages and Traction Engines,” by Fletcher (Longmans. 15s. net); “Petrol Motors, and Motor Cars,” by Hyler White (Longmans. 4s. 6d. net); “Motor Vehicles, and Motors,” by Beaumont (Constable. 2 vols., 84s. net); “O'Gorman's Motor Pocket Book,” by O'Gorman (Constable. 7s. 6d. net).

Drawing and Design. “A Manual of Machine Drawing and Design,” by Low and Bevis (Longmans. 7s. 6d.); “Elements of Machine Design,” by Unwin (Longmans. Part I., 7s. 6d.; Part 2, 6s.); “A Text Book of Engineering Drawing and Design,” by Wells (Griffin. 2 vols., 9s.); “Sketches of Engine and Machine Details,” by Bentley (Chapman & Hall. 2s. 9d.); “Drawing, and Rough Sketching for Marine Engineers,” by Donaldson (Norie & Wilson, Minories, London); “Mathematical Instruments,” by Stanley (Spon. 5s.).

Mechanics. “The Mechanics of Machinery,” by Kennedy (Macmillan & Co., Ltd., London. 8s. 6d.); “The Constructor,” by Reuleaux (Engineering Magazine Office, London. 30s.); “Applied Mechanics,” by Cotterill (Macmillan. 18s.); “Applied Mechanics,” by Jamieson (Griffin. Vol. 1, 8s. 6d.; Vol. 2, 12s. 6d.); “Mechanical Movements,” by Barber (Spon); “Mechanical Movements, Powers, Devices, and Appliances,” by Hiscox (Constable. 12s. 6d. net); “Rope Driving,” by Flather (Chapman & Hall. 8s. 6d. net); “Dynamometers, and the Measurement of Power,” by Flather (Chapman & Hall. 12s. 6d. net); “A Manual of Machinery and Millwork,” by Rankine (Griffin. 12s. 6d.); “A Manual of Applied Mechanics,” by Rankine (Griffin. 12s. 6d.); “Friction and Lost Work,” by Thurston (Chapman & Hall. 12s. 6d. net); “Kinematics,” by Weisbach (Chapman & Hall. 21s. net); “Machinery of Transmission, and Governors,” by Weisbach (Chapman & Hall. 21s. net).

Materials. “The Materials of Engineering,” by Thurston (Chapman & Hall. In three parts, 8s. 6d., 15s., 10s. 6d. net); “A Text Book of the Materials of Construction,” by Thurston (Chapman & Hall. 21s. net); “Strains in Iron Work,” by Adams (Spon. 5s.); “Handy Book for the Calculation of Strains in Girders,” by Humber (Spon. 7s. 6d.); “Stresses and Thrusts,” by Middleton (Batsford, London. 5s.); “The Strength of Materials and Structures,” by Anderson (Longmans. 3s. 6d.).

Hoisting and Conveying. “The Mechanical Handling of Material,” by Zimmer (Lockwood. 25s. net); “Hoisting Machinery,” by Horner (Lockwood. 7s. 6d. net); “Aerial or Wire Rope Tramways,” by Wallis-Taylor (Lockwood. 7s. 6d.); “The Mechanics of Hoisting Machinery,” by Weisbach & Herriman (Macmillan. 12s. 6d. net); “Belting,” by Halliday (Spon. 3s. 6d.); “Belting,” by Cooper (Spon. 12s. 6d. net); “Toothed Gearing,” by Cromwell (Chapman & Hall. 6s. 6d. net); “Helical Gears,” by Horner (Whittaker. 5s.).

Railway Engineering. “British Locomotives,” by Cooke (Whittaker. 7s. 6d.); “Locomotive Engine Running and Management,” by Sinclair (Chapman & Hall. 8s. 6d. net); “Recent Developments in Locomotive Practice,” by Cooke (Whittaker. 2s. 6d.); “The Working and Management of an English Railway,” by Findlay (Whittaker. 7s. 6d.); “The Midland Railway,” by Williams (Bentley. 12s.); “Our Iron Roads,” by Williams (Bentley); “The Railways of England,” by Ackworth (Murray. 12s.); “Steam Locomotives,” by Pendred (Constable. 6s.); “Locomotive Engineering,” by Pettigrew and Ravenshaw (Griffin. 21s.); “Catechism of the Locomotive,” by Forney (Spon. 15s. net); “Modern Locomotive Construction,” by Meyer (Chapman & Hall. 42s. net); “The Construction of the Modern Locomotive,” by Hughes

(Spon. 9s.); "Railway Brakes," by Blackall (Spon. 8s. 6d. net); "Railway Construction and Maintenance," by Cole (Spon. 7s. 6d. net); "Railway Track and Track Work," by Tratman (Constable. 12s. 6d. net); "Light Railways," by Cole (Griffin. 16s.); "The Inspection of Railway Material," by Bodmer (Whittaker. 5s.).

Bridge and Girder Work. "A Practical Treatise on Bridge Construction," by Claxton Fidler (Griffin. 30s.); "The Design of Beams," by Atherton (Griffin. 6s. net); "Ironwork," by Adams (Spon. First series, 8s. 6d; Second series. 8s.); "Constructional Steelwork," by Farnsworth (Constable. 10s. 6d. net).

Pumps and Hydraulics. "Hydraulic Power and Hydraulic Machinery," by Robinson (Griffin. 34s.); "Pumping Machinery," by Davey (Griffin. 21s. net); "Hydraulic Machinery," by Blaine (Spon. 14s. net); "Hydraulic Motors," by Björling (Spon. 9s.); "Hydraulics," by Box (Spon. 5s. net); "Pump Construction," by Björling (Spon. 5s.); "Pumps," by Björling (Spon. 30s. net); "Pump Details," by Björling (Spon. 7s. 6d.); "Hydraulic Motors and Turbines," by Bodmer (Whittaker. 15s.); "Pumps," by Colyer (Spon. Part I., 28s.; Part II., 25s.); "Centrifugal Pumps, Turbines, etc.," by Innes (Tech. P. Co. 4s. 6d.); "Turbines," by Wood (Chapman & Hall. 10s. 6d. net); "Hydraulics and Hydraulic Motors," by Wiesbach (Chapman & Hall. 21s.).

Miscellaneous Subjects. "Lubrication and Lubricants," by Archbutt and Deeley (Griffin); "Aid Book to Engineering Enterprise," by Matheson (Spon. 24s.); "Depreciation," by Matheson (Spon. 7s. 6d. net); "Factories and Workshops," by Thwaite (Spon. 9s.); "Warming Buildings," by Dye (Spon. 10s. net); "Warming and Ventilating," by Dye (Spon. 8s. 6d. net); "Heating by Hot Water," by Jones (Lockwood. 6s.); "Hot Water Supply," by Dye (Spon. 3s. net); "Rustless Coatings," by Wood (Chapman & Hall. 17s. net); "Pipes and Tubes," by Björling (Whittaker. 3s. 6d. net); "Ice Making," by Redwood (Spon. 4s. 6d. net); "Marine Propellers," by Barnaby (Spon. 10s. 6d. net); "Workshop Costs," by Pearn (Tech. P. Co. 12s. 6d.); "Refuse Disposal and Power Production," by Goodrich (Constable. 21s. net); "Small Dust Destructors," by Goodrich (Constable. 4s.); "Compressed Air," by Richards (Chapman & Hall. 6s. 6d. net); "Steam Heating for Buildings," by Baldwin (Chapman & Hall. 10s. 6d. net).
